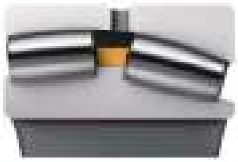
Asymmetrical Spherical Roller Bearings

for Wind Turbine Main Shafts

CAT. No. 3038／E

Asymmetric design of left and right roller rows

Longer operating life and better wear-resistance characteristics



Asymmetrical Spherical Roller Bearings for Wind Turbine Main Shafts

Next generation bearings delivering innovation to wind power generation

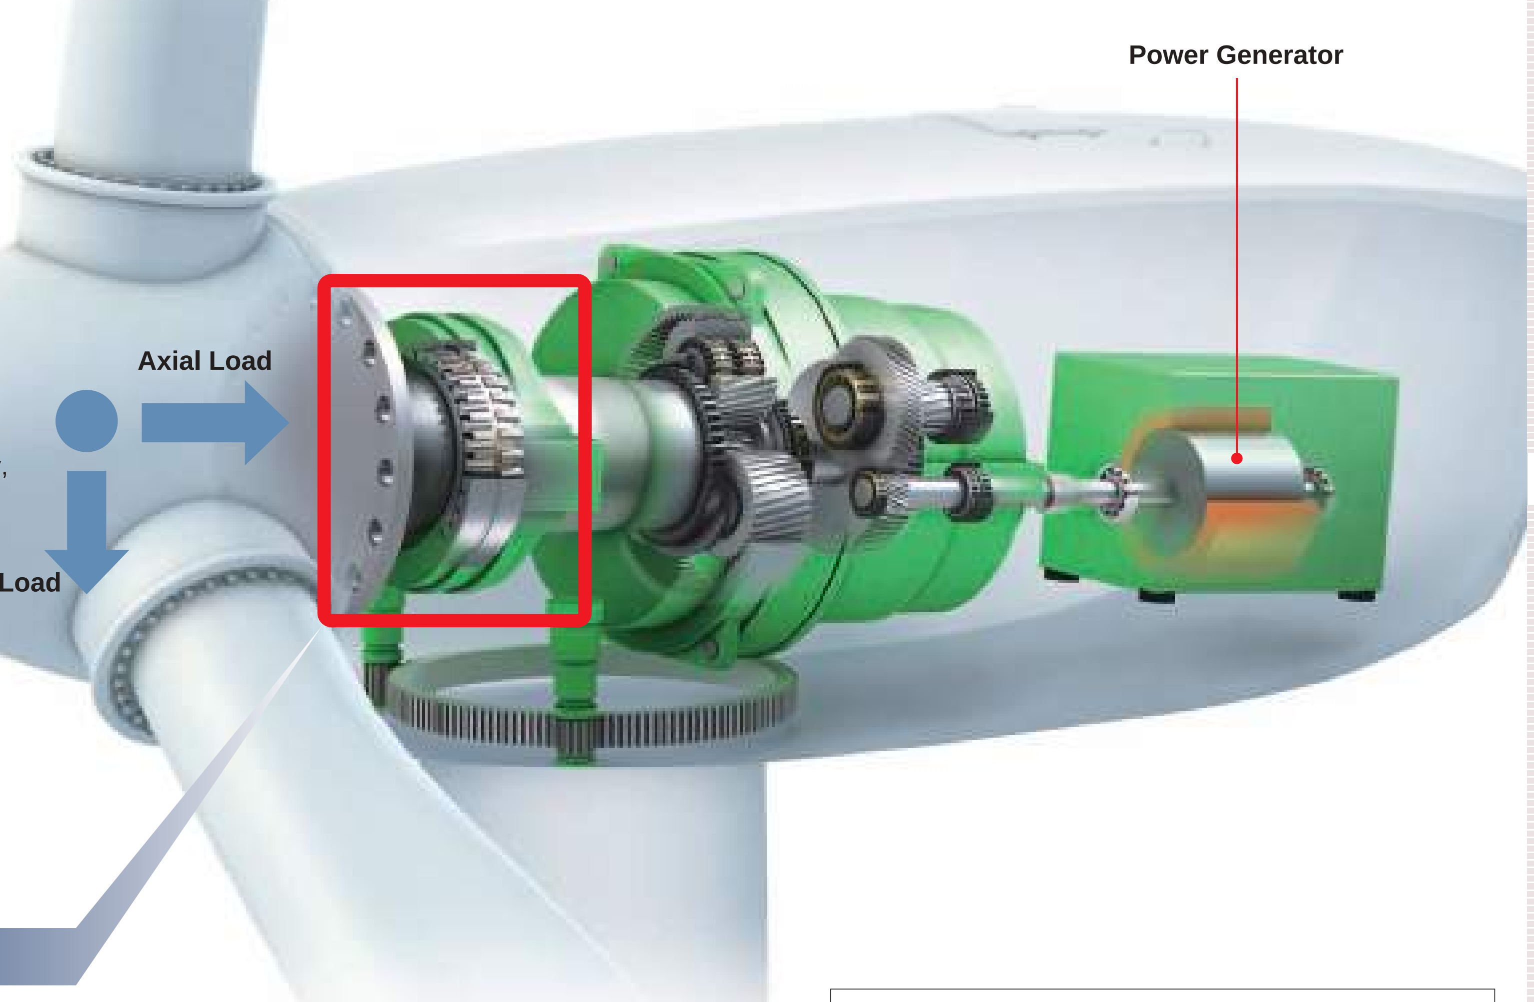
NTN

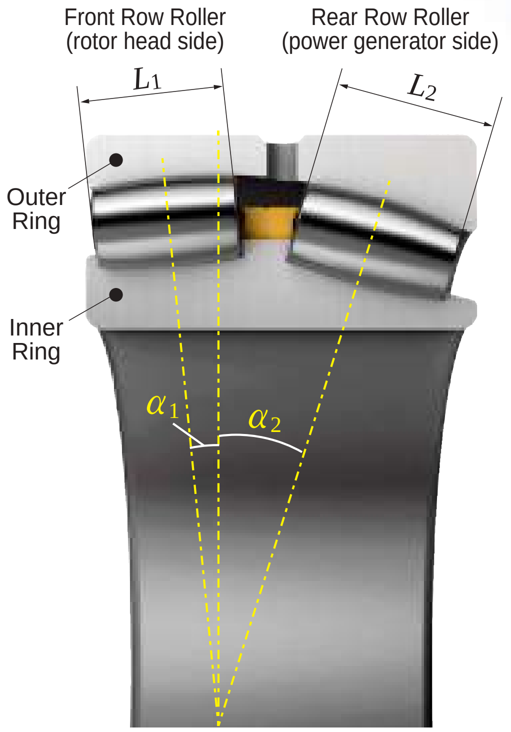
Asymmetric design of left and right roller rows for

longer operating life and better wear-resistance characteristics

Wind turbine main shaft bearings are subjected to axial loading caused by wind loads, in addition to radial loads from the weight of components including the rotors and blades. The use of spherical roller bearings for such applications results in the rear row (power generator side) being subjected to large loads while the front row is more lightly loaded (see **Fig. 1**). Additionally, spherical roller bearings have a characteristic of rolling and sliding due to inherent internal geometry.*1 These conditions, combined with insufficient lubrication at the roller/raceway contact, lead to wear at the raceway surface in areas with a high PV value.*2 As a result, damage might occur, particularly in the outer ring of the rear side.

Asymmetrical spherical roller bearings for wind turbine main shafts have an asymmetrical design of the internal left and right roller rows. This allows the left and right roller rows to distribute loads more evenly, giving the bearings a longer operating life and better wear-resistance characteristics compared to conventional spherical roller bearings.





Design specifications of the developed product

- ▷**Contact angle** : $\alpha_2 > \alpha_1$ (α_1: front row contact angle, α_2: rear row contact angle)
- ▷**Roller length** : $L_2 > L_1$ (L_1: front row roller length, L_2: rear row roller length)
- ▷**Cage design** : separate brass cages for left and right rows
- ▷**Inner ring design** : with inner ring center rib
- ▷**Roller design** : asymmetrical rollers (with maximum roller diameter position towards the bearing center)

*1 Rolling sliding: sliding caused by the difference in speeds between the contact areas of the roller and raceway surface in the direction of rotation
*2 PV value: value combining the contact surface pressure [P] and rolling sliding velocity [V].
*3 Compared with **NTN**'s conventional products (calculated by **NTN** under average fatigue load conditions acting on wind turbine main shaft bearings)
*4 When the rollers in roller bearings tilt away from the correct rotating axis

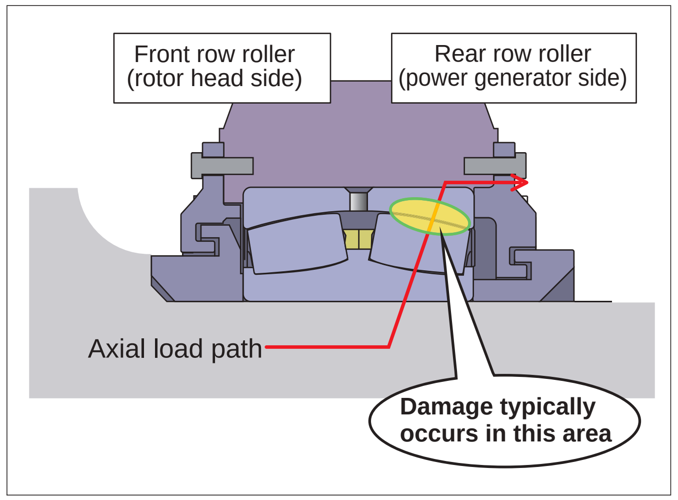


Fig. 1 Axial load acting on wind turbine main shaft bearing

Features

- **Asymmetric design of left/right roller rows:**
  Asymmetric bearing design with different length and contact angles between the rollers in the left and right rows
- **Increased wear-resistance:**
  Better wear-resistance characteristics due to a reduction in PV value*2 of approximately 30%*3
- **Extended operating life:**
  Approximately 2.5-times*3 longer life when compared to theoretical life of the standard product

Compared to conventional products, the contact angle of the developed product is smaller at the front row and larger at the rear row. Additionally, the length of the rear row is longer than the front row, allowing for more efficient support of axial loads from the wind on the rear row and better support of radial loading on the front row.

The asymmetric spherical roller bearing is designed with a central rib on the inner ring. The maximum diameter position of the roller is located towards the center of the inner ring to prevent roller skewing.*4

Solutions from NTN

Solution 1

An asymmetric spherical roller bearing design can be selected with the same boundary dimensions as the conventional product, resulting in longer theoretical operating life and better wear-resistance characteristics.

Solution 2

An asymmetric spherical roller bearing design can be selected with approximately 10% reduction in inner diameter and 30% reduction in weight to achieve a similar theoretical operating life as the conventional product.

CONTENTS

Warranty

NTN warrants, to the original purchaser only, that the delivered product which is the subject of this sale (a) will conform to drawings and specifications mutually established in writing as applicable to the contract, and (b) be free from defects in material or fabrication. The duration of this warranty is one year from date of delivery. If the buyer discovers within this period a failure of the product to conform to drawings or specifications, or a defect in material or fabrication, it must promptly notify **NTN** in writing. In no event shall such notification be received by **NTN** later than 13 months from the date of delivery. Within a reasonable time after such notification, **NTN** will, at its option, (a) correct any failure of the product to conform to drawings, specifications or any defect in material or workmanship, with either replacement or repair of the product, or (b) refund, in part or in whole, the purchase price. Such replacement and repair, excluding charges for labor, is at **NTN**'s expense. All warranty service will be performed at service centers designated by **NTN**. These remedies are the purchaser's exclusive remedies for breach of warranty.

NTN does not warrant (a) any product, components or parts not manufactured by **NTN**, (b) defects caused by failure to provide a suitable installation environment for the product, (c) damage caused by use of the product for purposes other than those for which it was designed, (d) damage caused by disasters such as fire, flood, wind, and lightning, (e) damage caused by unauthorized attachments or modification, (f) damage during shipment, or (g) any other abuse or misuse by the purchaser.

THE FOREGOING WARRANTIES ARE IN LIEU OF ALL OTHER WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE.

In no case shall **NTN** be liable for any special, incidental, or consequential damages based upon breach of warranty, breach of contract, negligence, strict tort, or any other legal theory,and in no case shall total liability of **NTN** exceed the purchase price of the part upon which such liability is based. Such damages include, but are not limited to, loss of profits, loss of savings or revenue, loss of use of the product or any associated equipment, cost of capital, cost of any substitute equipment, facilities or services, downtime, the claims of third parties including customers, and injury to property. Some states do not allow limits on warranties, or on remedies for breach in certain transactions. In such states, the limits in this paragraph and in paragraph (2) shall apply to the extent allowable under case law and statutes in such states.

Any action for breach of warranty or any other legal theory must be commenced within 15 months following delivery of the goods.

Unless modified in a writing signed by both parties, this agreement is understood to be the complete and exclusive agreement between the parties, superceding all prior agreements, oral or written, and all other communications between the parties relating to the subject matter of this agreement. No employee of **NTN** or any other party is authorized to make any warranty in addition to those made in this agreement.

This agreement allocates the risks of product failure between **NTN** and the purchaser. This allocation is recognized by both parties and is reflected in the price of the goods. The purchaser acknowledges that it has read this agreement, understands it, and is bound by its terms.

LARGE BEARINGS

TECHNICAL DATA CONTENTS

1. Load Rating and Life

1.1 Bearing life

Even in bearings operating under normal conditions, the surfaces of the raceway and rolling elements are constantly being subjected to repeated compressive stresses which cause flaking of these surfaces to occur. This flaking is due to material fatigue and will eventually cause the bearings to fail. The effective life of a bearing is usually defined in terms of the total number of revolutions a bearing can undergo before flaking of either the raceway surface or the rolling element surfaces occurs.

Other causes of bearing failure are often attributed to problems such as seizing, abrasions, cracking, chipping, gnawing, rust, etc. However, these so called "causes" of bearing failure are usually themselves caused by improper installation, insufficient or improper lubrication, faulty sealing or inaccurate bearing selection. Since the above mentioned "causes" of bearing failure can be avoided by taking the proper precautions, and are not simply caused by material fatigue, they are considered separately from the flaking aspect.

1.2 Basic rated life and basic dynamic load rating

A group of seemingly identical bearings when subjected to identical load and operating conditions will exhibit a wide diversity in their durability.

This "life" disparity can be accounted for by the difference in the fatigue of the bearing material itself. This disparity is considered statistically when calculating bearing life, and the basic rated life is defined as follows.

The basic rated life is based on a 90% statistical model which is expressed as the total number of revolutions 90% of the bearings in an identical group of bearings subjected to identical operating conditions will attain or surpass before flaking due to material fatigue occurs. For bearings operating at fixed constant speeds, the basic rated life (90% reliability) is expressed in the total number of hours of operation.

The basic dynamic load rating is an expression of the load capacity of a bearing based on a constant load which the bearing can sustain for one million revolutions (the basic life rating). For radial bearings this rating applies to pure radial loads, and for thrust bearings it refers to pure axial loads. The basic dynamic load ratings given in the bearing tables of this catalog are for bearings constructed of **NTN** standard bearing materials, using standard manufacturing techniques. Please consult **NTN** Engineering for basic load ratings of bearings constructed of special materials or using special manufacturing techniques.

The relationship between the basic rated life, the basic dynamic load rating and the bearing load is given in formula (1.1).

$$L_{10} = \left(\frac{C}{P}\right)^{p} \cdots\cdots\cdots\cdots (1.1)$$

where,

p= 3......................For ball bearings

p= 10/3.................For roller bearings

L_{10} : Basic rated life 10^6 revolutions

C : Basic dynamic rated load, N
(C_r: radial bearings, C_a: thrust bearings)

P : Equivalent dynamic load, N
(P_r: radial bearings, P_a: thrust bearings)

The basic rated life can also be expressed in terms of hours of operation (revolution), and is calculated as shown in formula (1.2).

$$L_{10h} = 500 f_h^{\,p} \cdots\cdots\cdots\cdots (1.2)$$

$$f_h = f_n \frac{C}{P} \cdots\cdots\cdots\cdots (1.3)$$

$$f_n = \left(\frac{33.3}{n}\right)^{1/p} \cdots\cdots\cdots (1.4)$$

where,

L_{10h} : Basic rated life, h

f_h : Life factor

f_n : Speed factor

n : Shaft speed, $\min^{-1}$

Formula (1.2) can also be expressed as shown in formula (1.5).

$$L_{10h} = \frac{10^6}{60n}\left(\frac{C}{P}\right)^{p} \cdots (1.5)$$

The relationship between Rotational speed n and speed factor f_n as well as the relation between the basic rated life L_{10h} and the life factor f_h is shown in **Fig. 1.1**.

When several bearings are incorporated in machines or equipment as complete units, all the bearings in the unit are considered as a whole when computing bearing life (see formula 1.6). The total bearing life of the unit is a life rating based on the viable lifetime of the unit before even one of the bearings fails due to rolling contact fatigue.

$$L = \frac{1}{\left(\frac{1}{L_1^{\,e}} + \frac{1}{L_2^{\,e}} + \cdots \frac{1}{L_n^{\,e}}\right)^{1/e}} \cdots\cdots\cdots (1.6)$$

where,

e = 10/9...................For ball bearings

e = 9/8.....................For roller bearings

L : Total basic rated life of entire unit, h

$L_1 . L_2 \cdots L_n$: Basic rated life of individual bearings, 1, 2, ⋯n, h

When the load conditions vary at regular intervals, the life can be given by formula (1.7).

$$L_m = \left(\Sigma \Phi_j / L_j\right)^{-1} \cdots\cdots\cdots\cdots\cdots\cdots\cdots (1.7)$$

where,

Φ_j : Frequency of individual load conditions

L_j : Life under individual conditions

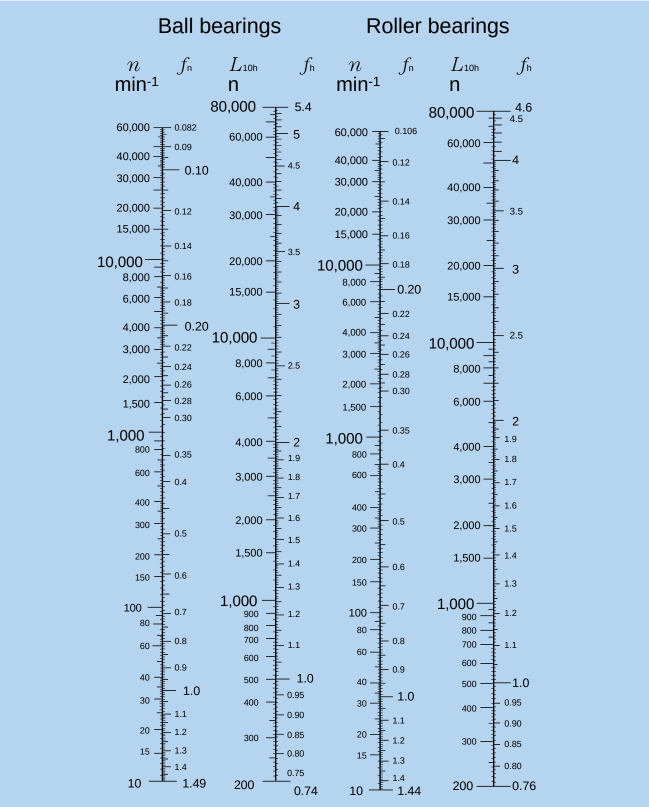

Fig. 1.1 Bearing life rating scale

1.3 Adjusted life rating factor

The basic bearing life rating (90% reliability factor) can be calculated through the formulas mentioned earlier in Section 1.2. However, in some applications a bearing life factor of over 90% reliability may be required. To meet these requirements, bearing life can be lengthened by the use of specially improved bearing materials or special construction techniques. Moreover, according to elastohydrodynamic lubrication theory, it is clear that the bearing operating conditions (lubrication, temperature, shaft speed, etc.) all exert an effect on bearing life. All these adjustment factors are taken into consideration when calculating bearing life, and using the life adjustment factor as prescribed in ISO 281, the adjusted bearing life can be determined.

$$L_{na} = a_1 \cdot a_2 \cdot a_3 \cdot (C/P)^p \quad \cdots \quad (1.8)$$

where,

L_{na} : Adjusted life rating in millions of revolutions (10^6)(adjusted for reliability, material and operating conditions)

a_1 : Reliability adjustment factor

a_2 : Material adjustment factor

a_3 :Operating condition adjustment factor

1.3.1 Life adjustment factor for reliability a_1

The values for the reliability adjustment factor a_1 (for a reliability factor higher than 90%) can be found in **Table 1.1**.

Table 1.1 Reliability adjustment factor values a_1

Reliability %	L_n	Reliability factor a_1
90	L_{10}	1.00
95	L_5	0.62
96	L_4	0.53
97	L_3	0.44
98	L_2	0.33
99	L_1	0.21

1.3.2 Life adjustment factor for material a_2

The life of a bearing is affected by the material type and quality as well as the manufacturing process. In this regard, the life is adjusted by the use of an a_2 factor.

The basic dynamic load ratings listed in the catalog are based on **NTN**'s standard material and manufacturing processes, therefore, the adjustment factor a_2=1. When special materials or processes are used the adjustment factor can be larger than 1.

NTN bearings can generally be used up to 120°C. If bearings are operated at a higher temperature, the bearing must be specially heat treated (stabilized) so that inadmissible dimensional change does not occur due to changes in the micro-structure. This special heat treatment might cause the reduction of bearing life because of a hardness change.

1.3.3 Life adjustment factor a_3 for operating conditions

The operating conditions life adjustment factor a_3 is used to adjust for such conditions as lubrication, operating temperature, and other operation factors which have an effect on bearing life.

Generally speaking, when lubricating conditions are satisfactory, the a_3 factor has a value of one; and when lubricating conditions are exceptionally favorable, and all other operating conditions are normal, a_3 can have a value greater than one.

However, when lubricating conditions are particularly unfavorable and the oil film formation on the contact surfaces of the raceway and rolling elements is insufficient, the value of a_3 becomes less than one. This insufficient oil film formation can be caused, for example, by the lubricating oil viscosity being too low for the operating temperature (below 13 mm^2/s for ball bearings; below 20 mm^2/s for roller bearings); or by exceptionally low rotational speed ($n$min^{-1} x $d_p$mm less than 10,000). For bearings used under special operating conditions, please consult **NTN** Engineering.

As the operating temperature of the bearing increases, the hardness of the bearing material decreases. Thus, the bearing life correspondingly decreases. The operating temperature adjustment values are shown in **Fig. 1.2**.

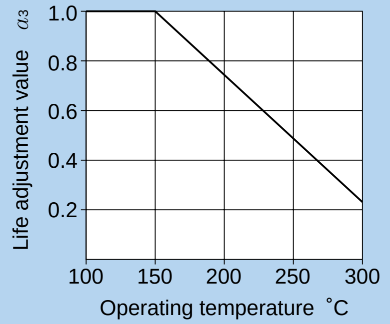

Fig. 1.2 Life adjustment value for operating temperature

1.4 Basic static load rating

When stationary rolling bearings are subjected to static loads, they suffer from partial permanent deformation of the contact surfaces at the contact point between the rolling elements and the raceway. The amount of deformity increases as the load increases, and if this increase in load exceeds certain limits, the subsequent smooth operation of the bearings is impaired.

It has been found through experience that a permanent deformity of 0.0001 times the diameter of the rolling element, occurring at the most heavily stressed contact point between the raceway and the rolling elements, can be tolerated without any impairment in running efficiency.

The basic rated static load refers to a fixed static load limit at which a specified amount of permanent deformation occurs. It applies to pure radial loads for radial bearings and to pure axial loads for thrust bearings. The maximum applied load values for contact stress occurring at the rolling element and raceway contact points are given below.

For ball bearings (except self-aligning ball bearings)	4,200 Mpa
For self-aligning ball bearings	4,600 Mpa
For roller bearings	4,000 Mpa

1.5 Allowable static equivalent load

Generally the static equivalent load which can be permitted (See Section 2.3.2 page A-9) is limited by the basic static rated load as stated in **Section 1.4**. However, depending on requirements regarding friction and smooth operation, these limits may be greater or lesser than the basic static rated load.

In the following formula (1.9) and **Table 1.2** the safety factor S_o can be determined considering the maximum static equivalent load.

$$S_o = C_o / P_o \cdots \quad (1.9)$$

where,

S_o : Safety factor
C_o : Basic static rated load, N
(radial bearings: C_{or}, thrust bearings: C_{oa})
$P_{o\,max}$: Maximum static equivalent load, N
(radial: P_{or} max, thrust: C_{oa} max)

Table 1.2 Minimum safety factor values S_0

Operating conditions	Ball bearings	Roller bearings
High rotational accuracy demand	2	3
Normal rotating accuracy demand (Universal application)	1	1.5
Slight rotational accuracy deterioration permitted (Low speed, heavy loading, etc.)	0.5	1

Notes: 1. For spherical thrust roller bearings, min. S_0 value=4.
2. For shell needle roller bearings, min. S_0 value=3.
3. When vibration and/or shock loads are present, a load factor based on the shock load needs to be included in the P_0 max value.
4. If a large axial load is applied to deep groove ball bearings or angular ball bearings, the contact oval may exceed the raceway surface. For more information, please contact **NTN** Engineering.

2. Bearing Load Calculation

To compute bearing loads, the forces which act on the shaft being supported by the bearing must be determined. These forces include the inherent dead weight of the rotating body (the weight of the shafts and components themselves), loads generated by the working forces of the machine, and loads arising from transmitted power.

It is possible to calculate theoretical values for these loads; however, there are many instances where the load acting on the bearing is usually determined by the nature of the load acting on the main power transmission shaft.

2.1 Load acting on shafts

2.1.1 Load factor

There are many instances where the actual operational shaft load is much greater than the theoretically calculated load, due to machine vibration and/or shock. This actual shaft load can be found by using formula (2.1)

$$K = f_w \cdot K_c \cdots \quad (2.1)$$

where:

K : Actual shaft load N {kgf}
f_w : Load factor (**Table 2.1**)
K_c : Theoretically calculated value N {kgf}

Table 2.1 Load factor f_w

Amount of shock	f_w	Application
Very little or no shock	1.0～1.2	Electrical machines, machine tools, measuring instruments.
Light shock	1.2～1.5	Railway vehicles, automobiles, rolling mills, metal working machines, paper making machines, rubber mixing machines, printing machines, aircraft, textile machines, electrical units, office machines.
Heavy shock	1.5～3.0	Crushers, agricultural equipment, construction equipment, cranes.

2.2 Mean load

The load on bearings used in machines under normal circumstances will, in many cases, fluctuate according to a fixed time period or planned operation schedule. The load on bearings operating under such conditions can be converted to a mean load (F_m), this is a load which gives bearings the same life they would have under constant operating conditions.

(1) Fluctuating stepped load

The mean bearing load, F_m, for stepped loads is calculated from formula (2.2). F_1 , F_2 .... F_n are the loads acting on the bearing; n_1, n_2.......n_n and t_1, t_2....... t_n are the bearing speeds and operating times respectively.

$$F_m = \left[\frac{\Sigma (F_i{}^p \, n_i \, t_i)}{(n_i \, t_i)} \right]^{1/p} \cdots\cdots\cdots\cdots\cdots\cdots \quad (2.2)$$

where:

$p=3$ For ball bearings
$p=10/3$ For roller bearings

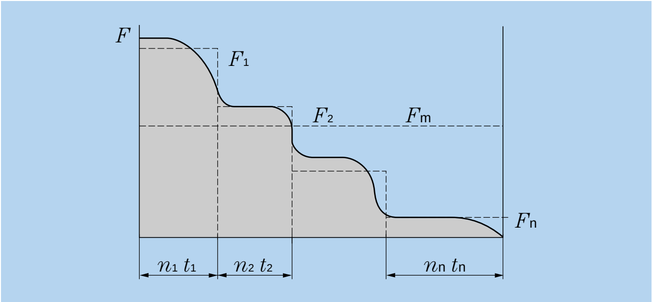

Fig. 2.1 Stepped load

(2) Consecutive series load

Where it is possible to express the function $F(t)$ in terms of load cycle to and time t, the mean load is found by using formula (2.3).

$$F_m = \left[\frac{1}{t_o} \int_o^{t_o} F(t)^p \, d_t \right]^{1/p} \cdots\cdots\cdots\cdots\cdots\cdots \quad (2.3)$$

where:

$p=3$ For ball bearings
$p=10/3$ For roller bearings

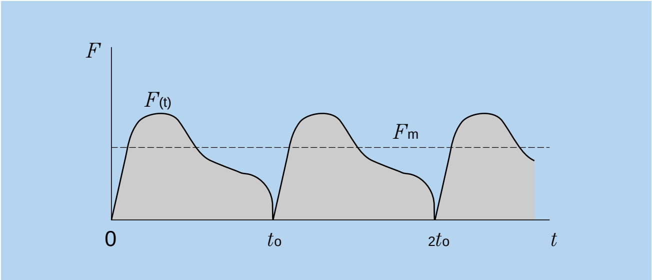

Fig. 2.2 Linear fluctuating load

(3) Linear fluctuating load

The mean load, F_m, can be approximated by formula (2.4).

$$F_m = \frac{F_{min} + 2F_{max}}{3} \cdots \quad (2.4)$$

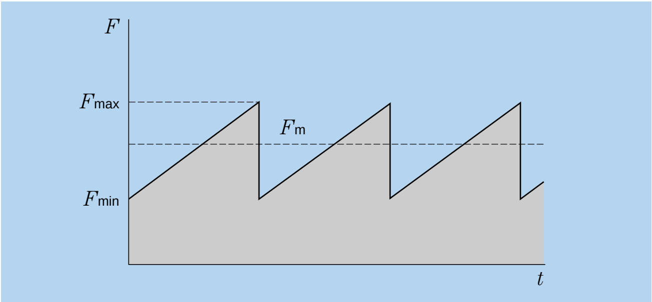

Fig. 2.3 Time function series load

(4) Sinusoidal fluctuating load

The mean load, F_m, can be approximated by formulas (2.5) and (2.6).

case (a) $F_m = 0.75 F_{max}$ ········ (2.5)

case (b) $F_m = 0.65 F_{max}$ ········ (2.6)

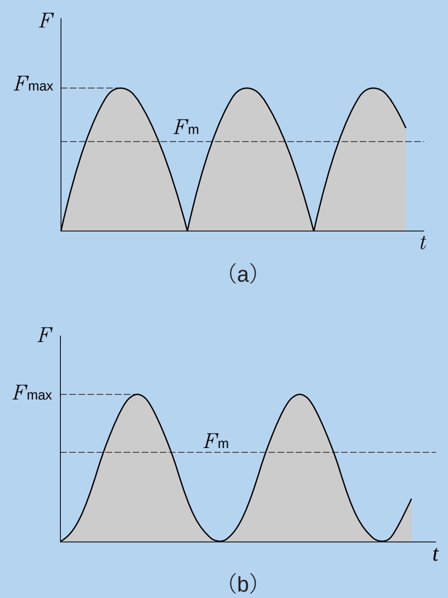

Fig. 2.4 Sinusoidal variable load

2.3 Equivalent load

2.3.1 Dynamic equivalent load

When both dynamic radial loads and dynamic axial loads act on a bearing at the same time, the hypothetical load acting on the center of the bearing giving the bearings the same life as if they had only a radial load or only an axial load, is called the dynamic equivalent load.

For radial bearings, this load is expressed as pure radial load and is called the dynamic equivalent radial load. For thrust bearings, it is expressed as pure axial load and is called the dynamic equivalent axial load.

(1) Dynamic equivalent radial load

The dynamic equivalent radial load is expressed by formula (2.7).

$$P_r = XF_r + YF_a \cdots\cdots\cdots\cdots\cdots\cdots \quad (2.7)$$

where,

P_r : Dynamic equivalent radial load, N
F_r : Actual radial load, N
F_a : Actual axial load, N
X : Radial load factor
Y : Axial load factor

The values for X and Y are listed in the bearing tables.

(2) Dynamic equivalent axial load

As a rule, standard thrust bearings with a contact angle of 90˚ cannot carry radial loads. However, self-aligning thrust roller bearings can accept some radial load. The dynamic equivalent axial load for these bearings is given in formula (2.8).

$$P_a = F_a + 1.2F_r \cdots\cdots\cdots\cdots\cdots\cdots \quad (2.8)$$

where,

P_a : Dynamic equivalent axial load, N
F_a : Actual axial load, N
F_r : Actual radial load, N

Provided that $F_r / F_a \leqq 0.55$ only.

2.3.2 Static equivalent load

The static equivalent load is a hypothetical load which would cause the same total permanent deformation at the most heavily stressed contact point between the rolling elements and the raceway as under actual load conditions; that is when both static radial loads and static axial loads are simultaneously applied to the bearing.

For radial bearings this hypothetical load refers to pure radial loads, and for thrust bearings it refers to pure centric axial loads. These loads are designated static equivalent radial loads and static equivalent axial loads respectively.

(1) Static equivalent radial load

For radial bearings the static equivalent radial load can be found by using formula (2.9) or (2.10). The greater of the two resultant values is always taken for P_{or}.

$$P_{or} = X_o F_r + Y_o F_a \cdots \quad (2.9)$$

$$P_{or} = F_r \cdots\cdots\cdots\cdots\cdots \quad (2.10)$$

where,

P_{or} : Static equivalent radial load, N
F_r : Actual radial load, N
F_a : Actual axial load, N
X_o : Static radial load factor
Y_o : Static axial load factor

The values for X_o and Y_o are given in the respective bearing tables.

(2) Static equivalent axial load

For spherical thrust roller bearings the static equivalent axial load is expressed by formula (2.11).

$$P_{oa} = F_a + 2.7F_r \cdots \quad (2.11)$$

where,

P_{oa} : Static equivalent axial load, N
F_a : Actual axial load, N
F_r : Actual radial load, N

Provided that $F_r / F_a \leqq 0.55$ only.

3. Bearing Tolerances

3.1 Dimensional accuracy and running accuracy

Bearing “tolerances” or dimensional accuracy and running accuracy, are regulated by ISO and JIS B 1514 standards (rolling bearing tolerances). For **dimensional accuracy**, these standards prescribe the tolerances necessary when installing bearings on shafts or in housings. **Running accuracy** is defined as the allowable limits for bearing runout during operation.

Dimensional accuracy

Dimensional accuracy constitutes the acceptable values for bore diameter, outer diameter, assembled bearing width, and bore diameter uniformity as seen in chamfer dimensions, allowable inner ring tapered bore deviation and shape error. Also included are, average bore diameter variation average, outer diameter variation, average outer diameter unevenness, as well as raceway width and height variation (for thrust bearings).

Running accuracy

Running accuracy constitutes the acceptable values for inner and outer ring radial runout and axial runout, inner ring side runout, and outer ring outer diameter runout.

Allowable rolling bearing tolerances have been established according to precision classes. JIS Class 0 corresponds to normal precision class bearings, and precision becomes progressively higher as the class number becomes smaller; i.e., Class 6 is less precise than Class 5, which is less precise than Class 4, and so on.

Table 3.1 indicates which standards and precision classes are applicable to the major bearing types. **Table 3.2** shows a relative comparison between JIS B 1514 precision class standards and other standards. For greater detail on allowable error limitations and values, refer to **Tables 3.3** - **3.8**. Allowable values for chamfer dimensions are shown in **Table 3.9**, and allowable error limitations and values for radial bearing inner ring tapered bores are shown in **Table 3.10**.

Table 3.1 Bearing types and applicable tolerance

❶ Applies to all radial flat planes of inner ring tapered bore.
❷ Does not apply to diameter series 7 and 8.

Note: Quantifiers

For a standard taper ratio of 1:12 $d1=d+\frac{1}{12}B$

For a standard taper ratio of 1:30 $d1=d+\frac{1}{30}B$

Δ_{dmp} : Dimensional difference of the average bore diameter within the flat surface at the theoretical small end of the tapered bore.

Δ_{d1mp} : Dimensional difference of the average bore diameter within the flat surface at the theoretical large end of the tapered bore.

V_{dp} : Unevenness of the bore diameter with the flat surface

B : Nominal width of inner ring

α : Half of the tapered bore's nominal taper angle
For a standard taper ratio of 1:12 $\alpha = 2°23'9.4''$
For a standard taper ratio of 1:30 $\alpha = 0°57'7.4''$

4. Bearing Fits

4.1 Interference

For rolling bearings, inner and outer rings are fixed on the shaft or in the housing so that relative movement does not occur between fitted surfaces during operation or under load. This relative movement (referred to as "creep") between the fitted surfaces of the bearing and the shaft or housing can occur in a radial direction, an axial direction, or in the direction of rotation. To help prevent this creeping movement, bearing rings and the shaft or housing are installed with one of three interference fits, a **"tight fit"** (also called shrink fit), **"transition fit,"** or **"loose fit"** (also called clearance fit), and the degree of interference between their fitted surfaces varies.

The most effective way to fix the fitted surfaces between a bearing's raceway and shaft or housing is to apply a **"tight fit."** The advantage of this tight fit for thin walled bearings is that it provides uniform load support over the entire ring circumference without any loss of load carrying capacity. However, with a tight fit, ease of installation and disassembly is lost; and when using a non-separable bearing as the floating-side bearing, axial displacement is not possible. For this reason, a tight fit cannot be recommended in all cases.

4.2 The necessity of a proper fit

In some cases, improper fit may lead to damage and shorten bearing life, therefore it is necessary to make a careful analysis in selecting a proper fit. Some of the negative conditions caused by improper fit are listed below.

- Raceway cracking, early peeling and displacement of raceway
- Raceway and shaft or housing abrasion caused by creeping and fretting corrosion
- Seizing caused by loss of internal clearances
- Increased noise and lowered rotational accuracy due to raceway groove deformation

4.3 Fit selection

Selection of a proper fit is dependent upon thorough analysis of bearing operating conditions, including consideration of:

- Shaft and housing material, wall thickness, finished surface accuracy, etc.
- Machinery operating conditions (nature and magnitude of load, rotational speed, temperature, etc.)

4.3.1 "Tight fit," "transition fit," or "loose fit"

(1) For raceways under rotating loads, a tight fit is necessary. (refer to **Table 4.1**) **"**Raceways under rotating loads**"** refers to raceways receiving loads rotating relative to their radial direction. For raceways under static loads, on the other hand, a loose fit is sufficient.
(Example) Rotating inner ring load = the direction of the radial load on the inner ring is rotating relatively

(2) For non-separable bearings, such as deep groove ball bearings, it is generally recommended that either the inner ring or outer ring be given a loose fit.

Table 4.1 Radial load and bearing fit

Illustration	Bearing rotation		Ring load	Fit
Static load 		Inner ring: Rotatring Outer ring: Stationary	Rotating inner ring load Static outer ring load	Inner ring : Tight fit Outer ring : Loose fit
Unbalanced load 		Inner ring: Stationary Outer ring: Rotating		
Static load 		Inner ring: Stationary Outer ring: Rotating	Static inner ring load Rotating outer ring load	Inner ring : Loose fit Outer ring : Tight fit
Unbalanced load 		Inner ring: Rotating Outer ring: Stationary		

4.3.2 Recommended Fits

Bearing fit is governed by the selection tolerances for bearing shaft diameters and housing bore diameters.

Widely used fits for 0 Class tolerance bearings and various shaft and housing bore diameter tolerances are shown in **Fig. 4.1**.

Generally-used, standard fits for most types of bearings and operating conditions are shown in **Tables 4.2** - **4.6**.

Table 4.2: Fits for radial bearings
Table 4.3: Fits for thrust bearings
Table 4.4: Fits for electric motor bearings
Table 4.5: Fits for inch series tapered roller bearings (ANSI Class 4)
Table 4.6: Fits for inch series tapered roller bearings (ANSI Class 3 and 0)
Table 4.5. shows fits and their numerical values.

For special fits or applications, please consult **NTN** Engineering.

4.3.3 Interference minimum and maximum values

The following points should be considered when it is necessary to calculate the interference for an application:

- In calculating the minimum required amount of interference keep in mind that:
  1) interference is reduced by radial loads
  2) interference is reduced by differences between bearing temperature and ambient temperature
  3) interference is reduced by variation of fitted surfaces
- Maximum interference should be no more than 1:1000 of the shaft diameter or outer diameter.

Required interference calculations are shown below.

(1) Radial loads and required interference

Interference between inner rings mounted on solid shafts is reduced when acted upon by radial loads. Calculation of the minimum required amount of interference in such cases is shown in formulae (4.1) and (4.2).

$F_r \leqq 0.3\, C_{or}$

$$\left.\begin{aligned}\Delta_{dF} &= 0.08\,(d \cdot F_r / B)^{1/2} \quad \text{N} \\ &= 0.25\,(d \cdot F_r / B)^{1/2} \quad \{\text{kgf}\}\end{aligned}\right\} \cdots\cdots\cdots (4.1)$$

$F_r > 0.3\, C_{or}$

$$\left.\begin{aligned}\Delta_{dF} &= 0.02\,(F_r / B) \quad \text{N} \\ &= 0.2\,(F_r / B) \quad \{\text{kgf}\}\end{aligned}\right\} \cdots\cdots\cdots (4.2)$$

Where,

Δ_{dF} : Required effective interference for load μm
d : Nominal bore diameter mm
B : Inner ring width mm
F_r : Radial load N {kgf}
C_{or} : Basic static rated load N {kgf}

(2) Temperature difference and required interference

Interference between inner rings and steel shafts is reduced as a result of temperature increases (difference between bearing temperature and ambient temperature, ΔT) caused by bearing rotation. Calculation of the minimum required amount of interference in such cases is shown in formulae (4.3).

$$\Delta_{dT} = 0.0015\, d\, \Delta T \cdots\cdots\cdots (4.3)$$

Δ_{dT} : Required effective interference for temperature difference μm
ΔT : Difference between bearing temperature and ambient temperature °C
d : Bearing bore diameter mm

(3) Fitted surface variation and required interference

Interference between fitted surfaces is reduced by roughness and other slight variations of these surfaces which are flattened in the fitting process. The degree of reduced interference depends upon the finish treatment of these surfaces, but in general it is necessary to assume the following interference reductions.

For ground shafts: 1.0～2.5 μm
For lathed shafts: 5.0～7.0 μm

(4) Maximum interference

When bearing rings are installed with an interference fit, tension or compression stress may occur along their raceways. If interference is too great, this may cause damage to the rings and reduce bearing life. For these reasons, maximum interference should not exceed the previously mentioned ratio of 1:1,000 of shaft or outside diameter.

4.3.4 Other details

(1) Tight interference fits are recommended for,
- Operating conditions with large vibration or shock loads
- Applications using hollow shafts or housings with thin walls
- Applications using housings made of light alloys or plastic

(2) Loose interference fits are preferable for,
- Applications requiring high running accuracy
- Applications using small sized bearings or thin walled bearings

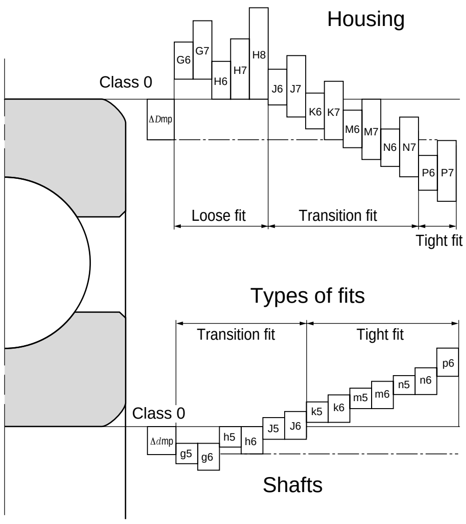

Fig. 4.1

(3) Consideration must also be given to the fact that fit selection will affect internal bearing clearance selection. (refer to page insert A-29)

(4) A particular type of fit is recommended for SL type cylindrical roller bearings.

Table 4.2 General standards for radial bearing fits (JIS Class 0, 6, 6X)

5. Bearing Internal Clearance

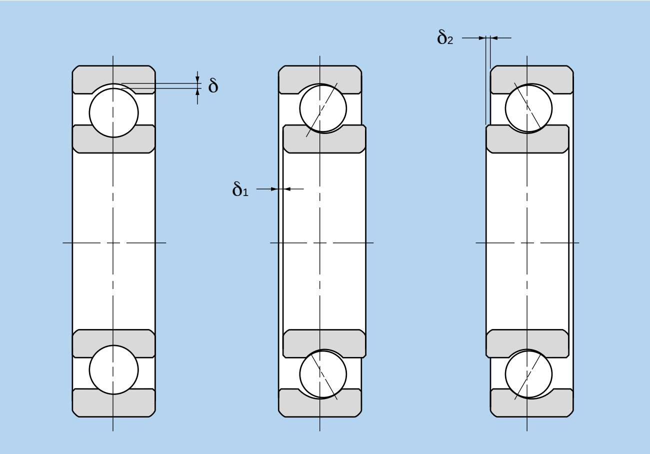
5.1 Bearing internal clearance

Bearing internal clearance (initial clearance) is the amount of internal clearance a bearing has before being installed on a shaft or in a housing.

As shown in **Fig. 5.1**, when either the inner ring or the outer ring is fixed and the other ring is free to move, displacement can take place in either an axial or radial direction. This amount of displacement (radially or axially) is termed the internal clearance and, depending on the direction, is called the radial internal clearance or the axial internal clearance.

When the internal clearance of a bearing is measured, a slight measurement load is applied to the raceway so the internal clearance may be measured accurately. However, at this time, a slight amount of elastic deformation of the bearing occurs under the measurement load, and the clearance measurement value (measured clearance) is slightly larger than the true clearance. This discrepancy between the true bearing clearance and the increased amount due to the elastic deformation must be compensated for. These compensation values are given in **Table 5.1**. For roller bearings the amount of elastic deformation can be ignored.

The internal clearance values for each bearing class are shown in **Tables 5.2** through **5.9**.



Radial clearance = δ Axial clearance = $\delta_1 + \delta_2$

Fig. 5.1 Internal clearance

5.2 Internal clearance selection

The internal clearance of a bearing under operating conditions (effective clearance) is usually smaller than the same bearing's initial clearance before being installed and operated. This is due to several factors including bearing fit, the difference in temperature between the inner and outer rings, etc. As a bearing's operating clearance has an effect on bearing life, heat generation, vibration, noise, etc.; care must be taken in selecting the most suitable operating clearance.

Effective internal clearance:

The internal clearance differential between the initial clearance and the operating (effective) clearance (the amount of clearance reduction caused by interference fits, or clearance variation due to the temperature difference between the inner and outer rings) can be calculated by the following formula:

$$\delta_{eff} = \delta_o - (\delta_f + \delta_t) \quad \cdots\cdots\cdots\cdots (5.1)$$

where,

δ_{eff} : Effective internal clearance, mm

δ_o : Bearing internal clearance, mm

δ_f : Reduced amount of clearance due to interference, mm

δ_t : Reduced amount of clearance due to temperature differential of inner and outer r, mm

Table 5.1 Examples of applications where bearing clearances other than normal clearance are used

Operating conditions	Applications	Selected clearance
With heavy or shock load, clearance is great.	Railway vehicle axles	C3
	Vibration screens	C3, C4
With direction indeterminate load, both inner and outer rings are tight-fitted.	Railway vehicle traction motors	C4
	Tractors and final speed regulators	C4
Shaft or inner ring is heated.	Paper making machines and driers	C3, C4
	Rolling mill table rollers	C3
To reduce shaft runout, clearance is adjusted.	Main spindles of lathes (Double-row cylindrical roller bearings)	C9NA, C0NA

(1) Reduced clearance due to interference

When bearings are installed with interference fits on shafts and in housings, the inner ring will expand and the outer ring will contract; thus reducing the bearings' internal clearance. The amount of expansion or contraction varies depending on the shape of the bearing, the shape of the shaft or housing, dimensions of the respective parts, and the type of materials used. The differential can range from approximately 70% to 90% of the effective interference.

$$\delta_f = (0.70 \sim 0.90)\,\Delta_{deff} \cdots\cdots\cdots\cdots (5.2)$$

where,

δ_f : Reduced amount of clearance due to interference, mm

Δ_{deff} : Effective interference, mm

(2) Reduced internal clearance due to inner/outer ring temperature difference.

During operation, normally the outer ring will range from 5 to 10℃ cooler than the inner ring or rotating parts. However, if the cooling effect of the housing is large, the shaft is connected to a heat source, or a heated substance is conducted through the hollow shaft; the temperature difference between the two rings can be even greater. The amount of internal clearance is thus further reduced by the differential expansion of the two rings.

$$\delta_t = \alpha \cdot \Delta T \cdot D_o \cdots\cdots\cdots\cdots (5.3)$$

where,

δ_t : Amount of reduced clearance due to heat differential, mm

α : Bearing steel linear expansion coefficient 12.5×10^{-6}/°C

ΔT : Inner/outer ring temperature differential, ℃

D_o : Outer ring raceway diameter, mm

Outer ring raceway diameter, D_o, values can be approximated by using formula (5.4) or (5.5).

For ball bearings and self-aligning roller bearings,

$$D_o = 0.20\,(d + 4.0D) \cdots\cdots\cdots\cdots (5.4)$$

For roller bearings (except self-aligning),

$$D_o = 0.25\,(d + 3.0D) \cdots\cdots\cdots\cdots (5.5)$$

where,

d : Bearing bore diameter, mm

D : Bearing outside diameter, mm

Notes: 1. This table applies to bearings contained in the catalog. For information concerning other bearings or bearings using US customary unit, please contact **NTN** Engineering.
2. The correlation of axial internal clearance (Δ_a) and radial internal clearance (Δ_r) is expressed as $\Delta_r = 0.667 \cdot e \cdot \Delta_a$.
e: Constant (see dimensions table)
3. Bearing series 329X, 330, 322C and 323Cdo not apply to the table.
4. This table shows **NTN** standard clearances.

6. Lubrication

6.1 Lubrication of rolling bearings

The purpose of bearing lubrication is to prevent direct metallic contact between the various rolling and sliding elements. This is accomplished through the formation of a thin oil (or grease) film on the contact surfaces. For rolling bearings, lubrication also has the following advantages:

(1) Friction and wear reduction
(2) Friction heat dissipation
(3) Prolonged bearing life
(4) Prevention of rust
(5) Protection against harmful elements

In order to achieve the above effects, the most effective lubrication method for the operating conditions must be selected. Also, a good quality, reliable lubricant must be selected. In addition, an effectively designed sealing system that prevents the intrusion of damaging elements (dust, water, etc.) into the bearing interior, removes dust and other impurities from the lubricant, and prevents the lubricant from leaking to the outside, is also a requirement.

Almost all rolling bearings use either grease or oil lubrication methods, but in some special applications, a solid lubricant such as molybdenum disulfide or graphite may be used.

Fig. 6.1 shows the relationship between oil volume, friction loss, and bearing temperature. **Table 6.1** details the characteristics of this relationship.

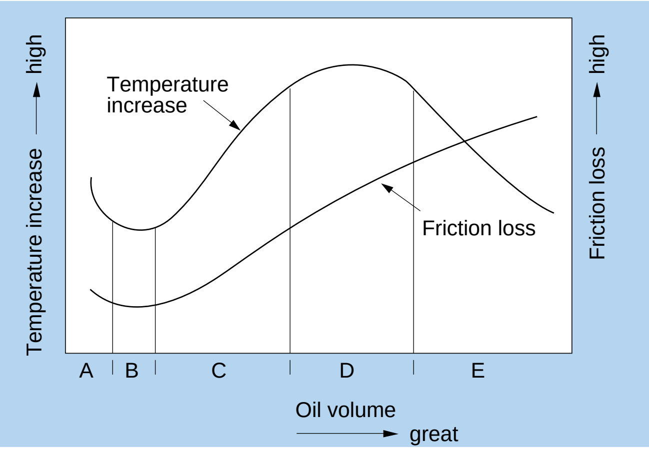

Fig. 6.1

Table 6.1 Oil volume, friction loss, bearing temperature (See Fig. 6.1)

Range	Characteristics	Lubrication method
A	When oil volume is extremely low, direct metallic contact occurs in places between the rolling elements and raceway surfaces. Bearing abrasion and seizing occur.	—
B	A thin oil film develops over all surfaces, friction is minimal and bearing temperature is low.	Grease lubrication, oil mist, air-oil lubrication
C	As oil volume increases, heat buildup is balanced by cooling.	Circulating lubrication
D	Regardless of oil volume, temperature increases at a fixed rate.	Circulating lubrication
E	As oil volume increases, cooling predominates and bearing temperature decreases.	Forced circulation lubrication, Oil jet lubrication

6.2 Characteristics of grease and oil lubricants

Grease and oil are the two general choices for lubrication: it is important to select lubricant with care. Please contact **NTN** Engineering when selecting a lubricant.
The characteristics are show in **table 6.2**.

Table 6.2 Comparison of grease lubrication and oil lubrication characteristics

Concern \ Method	Grease lubrication	Oil lubrication
Handling	◎	△
Reliability	○	◎
Cooling effect	×	○ (Circulation necessary)
Seal structure	○	△
Power loss	○	○
Environment contamination	○	△
High speed rotation	×	○

◎ : Very good ○ : Good △ : Fair × : Poor

6.3 Grease lubrication

Grease type lubricants are relatively easy to handle and require only the simplest sealing devices–for these reasons, grease is the most widely used lubricant for rolling bearings.

6.3.1 Types and characteristics of grease

Lubricating greases are composed of either a mineral oil base or a synthetic oil base. To this base a thickener and other additives are added. The properties of all greases are mainly determined by the kind of base oil used and by the combination of thickening agent and various additives.

Standard greases and their characteristics are listed in **Table 6.3**. As performance characteristics of even the same type of grease will vary widely from brand to brand, it is best to check the manufacturers' data when selecting a grease.

Table 6.3 Grease varieties and characteristics

Grease name	Lithium grease			Sodium grease (fiber grease)	Calcium compound base grease
Thickener	Li soap			Na soap	Ca+Na soap Ca+Li soap
Base oil	Mineral oil	Diester oil	Silicone oil	Mineral oil	Mineral oil
Dropping point ˚C	170 ～ 190	170 ～ 190	200 ～ 250	150 ～ 180	150 ～ 180
Operating temperature range ˚C	-30 ～ +130	-50 ～ +130	-50 ～ +160	-20 ～ +130	-20 ～ +120
Mechanical stability	Excellent	Good	Good	Excellent ～ Good	Excellent ～ Good
Pressure resistance	Good	Good	poor	Good	Excellent ～ Good
Water resistance	Good	Good	Good	Good ～ poor	Good ～ poor
Applications	Widest range of applications. Grease used in all types of rolling bearings.	Excellent low temperature and wear characteristics. Suitable for small sized and miniature bearings.	Suitable for high and low temperatures. Unsuitable for heavy load applications due to low oil film strength.	Some emulsification when water is introduced. Excellent characteristics at relatively high temperatures.	Excellent pressure resistance and mechanical stability. Suitable for bearings receiving shock loads.

Grease name	Aluminum grease	Non-soap base grease Thickener	
Thickener	Al soap	Bentone, silica gel, urea, carbon black, fluorine compounds, etc.	
Base oil	Mineral oil	Mineral oil	Synthetic oil
Dropping point ˚C	70 ～ 90	250 or above	250 or above
Operating temperature range ˚C	-10 ～ +80	-10 ～ +130	-50 ～ +200
Mechanical stability	Good ～ poor	Good	Good
Pressure resistance	Good	Good	Good
Water resistance	Good	Good	Good
Applications	Excellent viscosity characteristics. Suitable for bearings subjected to vibrations.	Can be used in a wide range of low to high temperatures. Shows excellent heat resistance, cold resistance, chemical resistance, and other characteristics when matched with a suitable base oil and thickener. Grease used in all types of rolling bearings.	

6.3.2 Base oil

Natural mineral oil or synthetic oils such as diester oil, silicone oil and fluorocarbon oil are used as grease base oils.

Mainly, the properties of any grease are determined by the properties of the base oil. Generally, greases with a low viscosity base oil are best suited for low temperatures and high speeds; while greases made from high viscosity base oils are best suited for heavy loads.

6.3.3 Thickening agents

Thickening agents are compounded with base oils to maintain the semi-solid state of the grease. Thickening agents consist of two types of bases, metallic soaps and non-soaps. Metallic soap thickeners include: lithium, sodium, calcium, etc.

Non-soap base thickeners are divided into two groups; inorganic (silica gel, bentonite, etc.) and organic (poly-urea, fluorocarbon, etc.).

The various special characteristics of a grease, such as limiting temperature range, mechanical stability, water resistance, etc. depend largely on the type of thickening agent used. For example, a sodium based grease is generally poor in water resistance properties, while greases with bentone, poly-urea and other non-metallic soaps as the thickening agent are generally superior in high temperature properties.

6.3.4 Additives

Various additives are added to greases to improve various properties and efficiency. For example, there are anti-oxidants, high-pressure additives (EP additives), rust preventives, and anti-corrosives.

For bearings subject to heavy loads and/or shock loads, a grease containing high-pressure additives should be used. For comparatively high operating temperatures or in applications where the grease cannot be replenished for long periods, a grease with an oxidation stabilizer is best to use.

6.3.5 Consistency

The consistency of a grease, i.e. the stiffness and liquidity, is expressed by a numerical index.

The NLGI values for this index indicate the relative softness of the grease; the larger the number, the stiffer the grease. The consistency of a grease is determined by the amount of thickening agent used and the viscosity of the base oil. For the lubrication of rolling bearings, greases with the NLGI consistency numbers of 1, 2, and 3 are used.

General relationships between consistency and application of grease are shown in **Table 6.4**.

Table 6.4 Consistency of grease

NLGI Consis-tency No.	JIS (ASTM) Worked penetration	Applications
0	355～385	For centralized greasing use
1	310～340	For centralized greasing use
2	265～295	For general use and sealed bearing use
3	220～250	For general and high temperature use
4	175～205	For special use

6.3.6 Mixing of greases

When greases of different kinds are mixed together, the consistency of the greases will change (usually softer), the operating temperature range will be lowered, and other changes in characteristics will occur. As a general rule, greases with different bases oil, and greases with different thickener agents should never be mixed.

Also, greases of different brands should not be mixed because of the different additives they contain.

However, if different greases must be mixed, at least greases with the same base oil and thickening agent should be selected. But even when greases of the same base oil and thickening agent are mixed, the quality of the grease may still change due to the difference in additives. For this reason, changes in consistency and other qualities should be checked before being applied.

6.3.7 Amount of grease

The amount of grease used in any given situation will depend on many factors relating to the size and shape of the housing, space limitations, bearing's rotating speed and type of grease used.

As a general rule, housings and bearings should be only filled from 30% to 60% of their capacities.

Table 6.5 Bearings space ratio K

Bearing type	Retainer type	K
Ball bearings ❶	Pressed retainer	61
NU-type cylindrical roller bearings ❷	Pressed retainer Machined retainer	50 36
N-type cylindrical roller bearings ❸	Pressed retainer Machined retainer	55 37
Tapered roller bearings	Pressed retainer	46
Spherical roller bearings	Pressed retainer Machined retainer	35 28

❶ Remove 160 series
❷ Remove NU4 series
❸ Remove N4 series

Where speeds are high and temperature rises need to be kept to a minimum, a reduced amount of grease should be used. Excessive amount of grease cause temperature rise which in turn causes the grease to soften and may allow leakage. With excessive grease fills oxidation and deterioration may cause lubricating efficiency to be lowered.

6.4 Solid grease (for bearings with solid grease)

"Solid grease" is a lubricant composed mainly of lubricating grease and ultra-high polymer polyethylene. Solid grease has the same viscosity as grease at normal temperature, but by applying a special heat treatment process, this special grease solidifies retaining a large proportion of the lubricant within the bearing. The result of this solidification is that the grease does not easily leak from the bearing, even when the bearing is subjected to strong vibrations or centrifugal force.

Bearings with solid grease are available in two types: the spot-pack type in which solid grease is injected into the retainer, and the full-pack type in which all empty space around the rolling elements is filled with solid grease.

Spot-pack solid grease is standard for deep groove ball bearings, small diameter ball bearings, and bearing units. Full-pack solid grease is standard for self-aligning ball bearings, self-aligning roller bearings, and needle roller bearings.

Primary advantages:

(1) Clean working environment with minimal grease leakage

(2) Low bearing torque with spot-pack type solid grease

For more details, please refer to the **NTN** special catalog for **Solid grease bearings**.

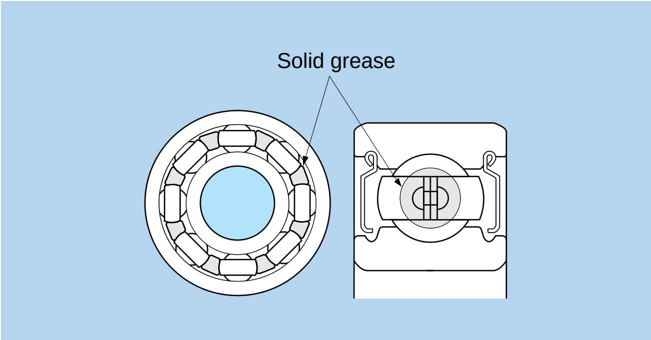

Fig. 6.3 Deep groove ball bearing with spot-pack solid grease (Z shield) (Standard for deep groove ball bearings)

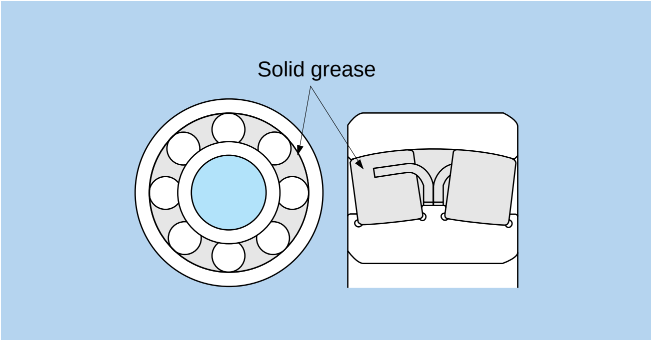

Fig. 6.4 Self-aligning roller bearing with full-pack solid grease (Standard for self-aligning roller bearings)

6.5 Oil lubrication

Oil lubrication is suitable for applications that require bearing-generated heat or heat applied to the bearing from other sources be carried away from the bearing and dissipated to the outside. **Table 6.6** shows the main methods of oil lubrication.

Table 6.6 Oil lubrication methods

Lubrication method	Example	Lubrication method	Example
(Oil bath lubrication) ● Oil bath lubrication is the most generally used method of lubrication and is widely used for low to moderate rotation speed applications. ● For horizontal shaft applications, oil level should be maintained at approximately the center of the lowest rolling element, according to the oil gauge, when the bearing is at rest. For vertical shafts at low speeds, oil level should be maintained at 50 - 80% submergence of the rolling elements.		**(Disc lubrication)** ● In this method, a partially submerged disc rotates and pulls oil up into a reservoir from which it then drains down through the bearing, lubricating it.	(Oil spray lubrication) ● In this method, an impeller or similar device mounted on the shaft draws up oil and sprays it onto the bearing. This method can be used at considerably high speeds.		**(Oil mist lubrication)** ● Using pressurized air, lubricating oil is atomized before passing through the bearing. ● Due to the low lubricant resistance, this method is well suited to high speed applications.	(Drip lubrication) ● In this method, oil is collected above the bearing and allowed to drip down into the housing where it becomes a lubricating mist as it strikes the rolling elements. Another version allows only slight amounts of oil to pass through the bearing. ● Used at relatively high speeds for light to moderate load applications. ● In most cases, oil volume is a few drops per minute.		**(Air-oil lubrication)** ● In this method, the required minimum amount of lubricating oil is measured and fed to each bearing at ideal intervals using compressed air. ● With fresh lubricating oil constantly being fed to the bearing, and with the cooling effect of the compressed air, bearing temperature rise can be minimized. ● Because the required oil quantity is infinitesimal, the working environment can be kept clean. Air-oil lubrication units are available from **NTN**.	(Circulating lubrication) ● Used for bearing cooling applications or for automatic oil supply systems in which the oil supply is centrally located. ● One of the advantages of this method is that oil cooling devices and filters to maintain oil purity can be installed within the system. ● In order for oil to thoroughly lubricate the bearing, oil inlets and outlets must be provided on opposite sides of the bearing.		**(Oil jet lubrication)** ● This method lubricates by injecting oil under high pressure directly into the side of the bearing. This is a reliable system for high speed, high temperature or otherwise severe conditions. ● Used for lubricating the bearings in jet engines, gas turbines, and other high speed equipment. ● Under-race lubrication for machine tools is one example of this type of lubrication.	
6.5.1 Selection of lubricating oil

Under normal operating conditions, **spindle oil**, **machine oil**, **turbine oil**, and other mineral oils are widely used for the lubrication of rolling bearings. However, for temperatures **above 150˚C or below -30˚C**, synthetic oils such as **diester oil**, **silicone oil**, and **fluorocarbon oil** are used.

For lubricating oils, viscosity is one of the most important properties and it determines an oil's lubricating efficiency. If viscosity is too low, formation of the oil film will be insufficient, and damage will occur to the load carrying surfaces of the bearing. If viscosity is too high, viscous resistance will also be great and result in temperature increases and friction loss. In general, for higher speed applications a lower viscosity oil should be used; for heavier load applications, a higher viscosity oil should be used.

In regard to operating temperature and lubrication, **Table 6.7** lists the required oil viscosity for different types of rolling bearings. **Fig. 6.3** is an oil viscosity–operating temperature comparison chart for the purpose of selecting a lubrication oil with viscosity characteristics appropriate to an application.

Table 6.8 lists the selection standards for lubricating oil viscosity with reference to bearing operating conditions.

Table 6.7 Required lubricating oil viscosity for bearings

Bearing type	Dynamic viscosity mm^2/s
Ball bearings, Cylindrical roller bearings, Needle roller bearings	13
Self-aligning roller bearings, Tapered roller bearings, Needle roller thrust bearings	20
Self-aligning roller thrust bearings	30

6.5.2 Oil quantity

In forced oil lubrication systems, the heat radiated away by the housing and surrounding parts plus the heat carried away by the lubricating oil is approximately equal to the amount of heat generated by the bearing and other sources.

For standard housing applications, the quantity of oil required can be found by formula (6.2).

$$Q = K \cdot q \quad \cdots\cdots (6.2)$$

where,

Q: Quantity of oil for one bearing cm^3/min.
K: Allowable oil temperature rise factor (**Table 6.9**)
q: Minimum oil quantity cm^3/min. (**Fig. 6.4**)

Because the amount of heat radiated will vary according to the type of housing, for actual operation it is advisable that the quantity of oil calculated by formula (6.2) be multiplied by a factor or 1.5 or 2.0. Then, the amount of oil can be adjusted to correspond to actual operating conditions.

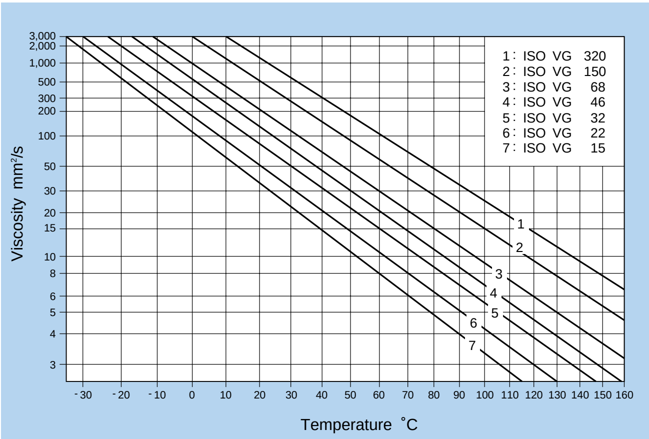

Fig. 6.3 Relation between lubricating oil viscosity and temperature

Table 6.8 Selection standards for lubricating oils (reference)

Bearing operating temperature ˚C	dn-value	Lubricating oil ISO viscosity grade (VG)		Suitable bearing
		Normal load	Heavy load or shock load	
−30〜 0	Up to allowable speed limiting	22, 32	46	All types
0〜 60	15,000 Up to	46, 68	100	All types
	15,000 〜80,000	32, 46	68	All types
	80,000 〜150,000	22, 32	32	All types but thrust ball bearings
	150,000〜500,000	10	22, 32	Single row radial ball bearings, cylindrical roller bearings
60〜100	15,000 Up to	150	220	All types
	15,000 〜80,000	100	150	All types
	80,000 〜150,000	68	100, 150	All types but thrust ball bearings
	150,000〜500,000	32	68	Single row radial ball bearings, cylindrical roller bearings
100 〜150	Up to allowable speed limiting	320		All types
0〜 60	Up to allowable speed limiting	46, 68		Self-aligning roller bearings
60〜100	Up to allowable speed limiting	150		

Notes: 1. Applied when lubrication method is either oil bath or circulating lubrication.
2. Please consult **NTN** Engineering in cases where operating conditions fall outside the range covered by this table.

Table 6.9 Factor K

Expelled oil temp minus supplied oil temp ˚C	K
10	1.5
15	1
20	0.75
25	0.6

Furthermore, if it is assumed for calculation purposes that no heat is radiated by the housing, and that all bearing heat is removed by the oil, then the value in **Fig. 6.3** for shaft diameter, d = 0, regardless of actual shaft diameter.

(Example) For tapered roller bearing **30220U** mounted on a flywheel shaft with a radial load of 9.5 kN (969 kgf), operating at 1,800 min^{-1}, what is the amount of lubricating oil required to keep the bearing temperature rise below 15˚C.

d = 100 mm,
dn = 100×1,800=18×10^4
From **Fig. 6.4** q = 180cm^3 / min
Assume the bearing temperature is approximately equal to the expelled oil temperature,
from **Table 6.9**, since K = 1
Q=1×180=180cm^3 / min

6.5.3 Relubrication intervals

The intervals at which lubricating oil should be changed varies depending upon operating conditions, oil quantity, and type of oil used. In general, for oil bath lubrication where the operating temperature is 50˚C or less, oil should be replaced once a year. When the operating temperature is between 80˚C – 100˚C, oil should be replaced at least every three months. For important equipment, it is advisable that lubricating efficiency and oil purity deterioration be checked regularly to determine when oil replacement is necessary.

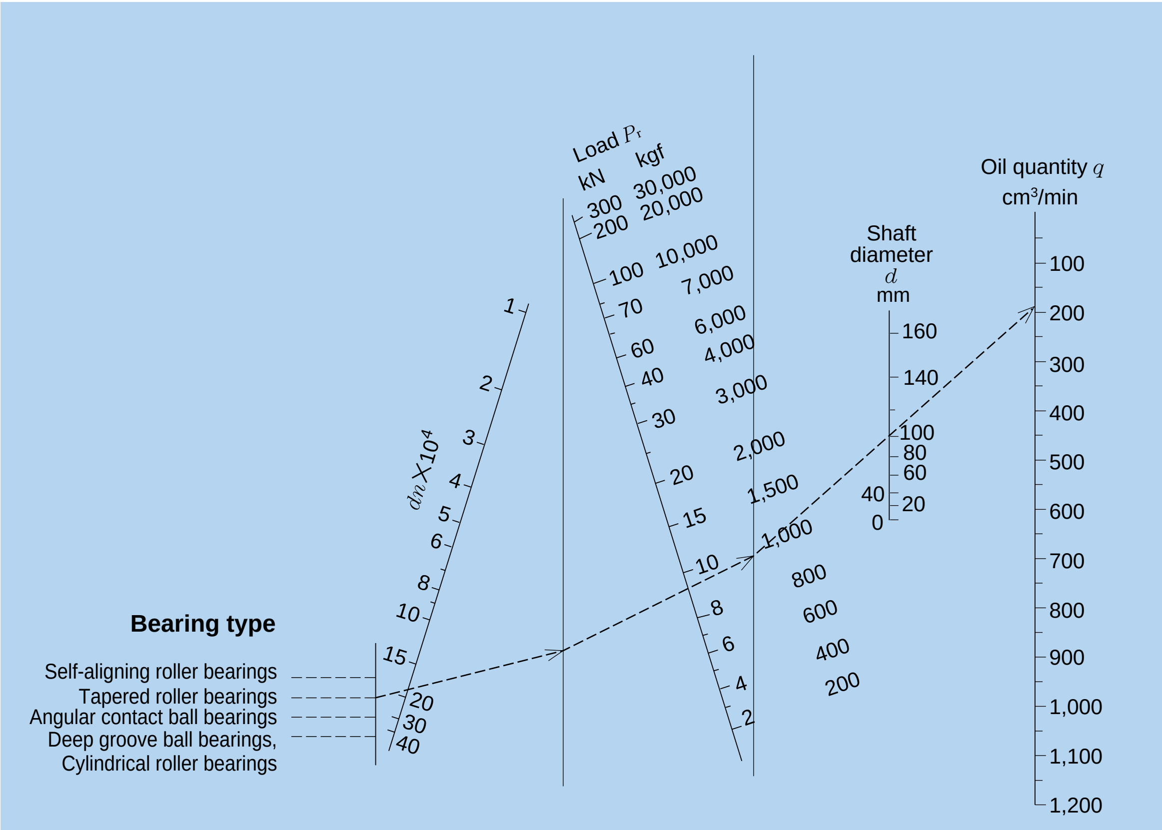

Fig. 6.4 Oil quantity guidelines

7. Bearing Materials

7.1 Raceway and rolling element materials

While the contact surfaces of a bearing's raceways and rolling elements are subjected to repeated heavy stress, they still must maintain high precision and rotational accuracy. To accomplish this, the raceways and rolling elements must be made of a material that has high hardness, is resistant to rolling fatigue, is wear resistant, and has good dimensional stability. The most common cause of fatigue cracking in bearings is the inclusion of non-metallic impurities in the steel. By using pure materials low in these non-metallic impurities, the rolling fatigue life of the bearing is lengthened.

For all **NTN** bearings, steel low in oxygen content and non-metallic impurities, then refined by a vacuum degassing process as well as outside hearth smelting, is used. For bearings requiring especially high reliability and long life, steels of even higher in purity, such as vacuum smelted steel (VIM, VAR, CEVM) and electro-slag melted steel (ESR), are used.

1) High/mid carbon alloy steel

In general, steel varieties which can be hardened not just on the surface but also deep hardened by the so-called "through hardening method" are used for the raceways and rolling elements of bearings. Foremost among these is high carbon chromium bearing steel, which is widely used. For large type bearings and bearings with large cross sectional dimensions, induction hardened bearing steel incorporating manganese or molybdenum is used. Also in use is mid-carbon chromium steel incorporating silicone and manganese, which gives it hardening properties comparable to high carbon chromium steel.

2) Case hardened (carburized) steel

Because of its combination of a hard surface layer which has been carburized and hardened to an appropriate depth, and a relatively pliable inner core, case hardened steel has excellent efficiency against shock loads. **NTN** uses case hardened steel for almost all of its tapered roller bearings. In terms of case hardened steel for **NTN**'s other bearings, chromium steel and chrome molybdenum steel are used for small to medium sized bearings, and nickel chrome molybdenum steel is used for large sized bearings.

3) Heat resistant bearing steel

When bearings made of ordinary high carbon chromium steel which have undergone standard heat treatment are used at temperatures above 120˚C for long durations, unacceptably large dimensional changes can occur. For this reason, a dimension stabilizing treatment (TS treatment) has been devised for very high temperature applications. Through application of this dimension stabilizing treatment, shortening of rolling fatigue life due to decreases in bearing hardness at high temperatures can be avoided. (refer to page insert A-6 1.3.2)

For standard high temperature bearings used at temperatures from 150˚C – 200˚C, the addition of silicone to the steel improves heat resistance and results in a bearing with excellent rolling fatigue life with minimal dimensional change or softening at high temperatures.

A variety of heat resistant steels are also incorporated in bearings to minimize softening and dimensional changes when used at high temperatures. Two of these are high speed molybdenum steel and high speed tungsten steel. For bearings requiring heat resistance in high speed applications, there is also heat resistant case hardening molybdenum steel.

4) Corrosion resistant bearing steel

For applications requiring high corrosion resistance, stainless steel is used. To achieve this corrosion resistance a large proportion of the alloying element chrome is added to martensite stainless steel.

5) Induction hardened steel

Besides the use of surface hardening steel, induction hardening is also utilized for bearing raceway surfaces, and for this purpose mid-carbon steel is used for its lower carbon content instead of through hardened steel. For induction hardening of the deep layers required for larger bearings and bearings with large surface dimensions, mid-carbon steel is fortified with chrome and molybdenum.

6) Other bearing materials

For ultra high speed applications and applications requiring very high level corrosion resistance, ceramic bearing materials such as Si_3N_4 are also available.

7.2 Cage materials

Bearing cage materials must have the strength to withstand rotational vibrations and shock loads. These materials must also have a low friction coefficient, be light weight, and be able to withstand bearing operation temperatures.

For small and medium sized bearings, pressed cages of cold or hot rolled steel with a low carbon content of approx. 0.1% are used. However, depending on the application, austenitic stainless steel is also used.

For large bearings, machined cages of machine structural carbon steel or high tensile cast brass are widely used, although aluminum alloy and other material cages are also available.

For aircraft engine bearings, high tensile brass, mid-carbon nickel, chrome, or molybdenum steel is used after undergoing various heat treatments and high temperature tempering. The sliding properties of these materials may also be enhanced when silver plated.

Injection molded plastic cages are now widely used: most are made from fiberglass reinforced heat resistant polyamide resin. Plastic cages are light weight, corrosion resistant and have excellent damping and sliding properties. Heat resistant polyamide resins now enable the production of cages that perform well in applications ranging between -40˚C – 120˚C. However, they are not recommended for use at temperatures exceeding 120˚C.

General Bearings

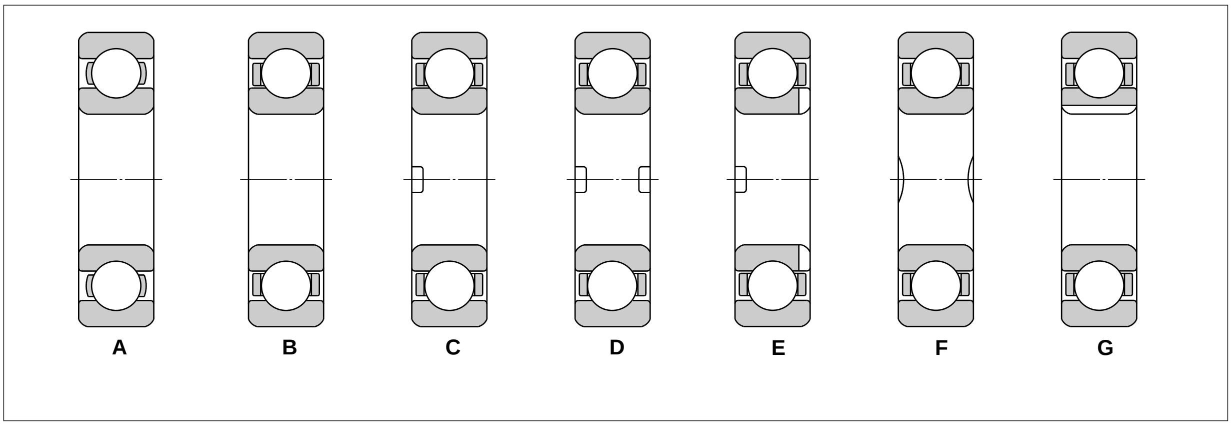
INDEX OF BEARING TABLES

Deep Groove Ball Bearings

1. Structure and Characteristics

A widely used bearing, the deep groove ball bearing takes its name from the track formed on both the inner and outer rings of the bearing. The bearings can sustain radial and axial loads and the resultant forces of these loads and they are suitable for high speed operation.

The dimensional table below represents the various cage models and special shapes. **Drawing A** is the pressed cage; **drawing B** shows the machined cage; **drawings C** through **F** show the position and shape of the notch on the inner ring; and **drawing G** shows a bearing with the key groove on the inner ring. Pressed cages are generally used, though machined cages are used for larger sized bearings, or bearings for high speed rotation.



Deep groove ball bearings drawing

2. Dimensional Accuracy/Rotation Accuracy

Refer to Table 3.3 (Page A-12)

3. Recommended Fitting

Refer to Table 4.2 (Page A-24)

4. Bearing Internal Clearance

Refer to Table 5.2 (Page A-30)

5. Permissible slant angle

0.0006-0.003 radian

6. General Operating Cautions

Slippage between the balls and raceways may occur when bearings are operated under small loads (about $F_r \leqq 0.01C_{or}$) and may cause smearing. This is most apparent when using large size deep groove ball bearings due to the large cage mass. Please consult **NTN** Engineering for further details.

Angular Contact Ball Bearings

1. Structure and Characteristics

1. 1 Single row angular contact ball bearings / duplex angular contact ball bearings

A line connecting the contact points of both the ball and inner ring and ball and outer ring forms an angle to a line drawn radially: that angle is called the contact angle.

An angular contact ball bearing, while designed for radial loads, can accommodate single direction axial loads. Under radial loads and the resulting axial force component, the bearings are generally used in a duplex arrangement. More information on types and characteristics of duplexed angular contact ball bearings is shown in **Table 1**.

Cage types and special features of single and multi–row angular contact ball bearings are show in **Fig.1**. **Drawings A** through **F** feature the inner ring guide cage. **Drawings B** and **C** illustrate cages with lubrication ports. **Drawings D** and **E** feature a rolling element guide cage: **E** also shows the cage with a lubrication port. Note that the inner ring width in **drawing F** is larger than that of the outer ring.

Table 1 Duplex angular contact ball bearings

Arrangement type		Characteristics	
Back-to-back duplex arrangement (Code: DB)		These bearings support the radial loads and both direction of axial loads.	● Since the distance "l" between the cone pressure apexes of bearing is large, the load capacity of the moment load is high. ● Permissible slant angle is small.
Face-to-face duplex arrangement (Code: DF)			● The distance "l" between the cone pressure apexes of bearing is small in comparison with the back-to-back duplex arrangement, the load capacity of the moment load is low. ● Permissible slant angle is larger than the back-to-back duplex arrangement type.

Notes: 1. Since the bearings are manufactured in a set to adjust for the internal clearance or pre-loading, **parts with same serial number must be used for assembly**.
2. Combination of more than 3 bearings may occur. Please consult **NTN Engineering** for details.

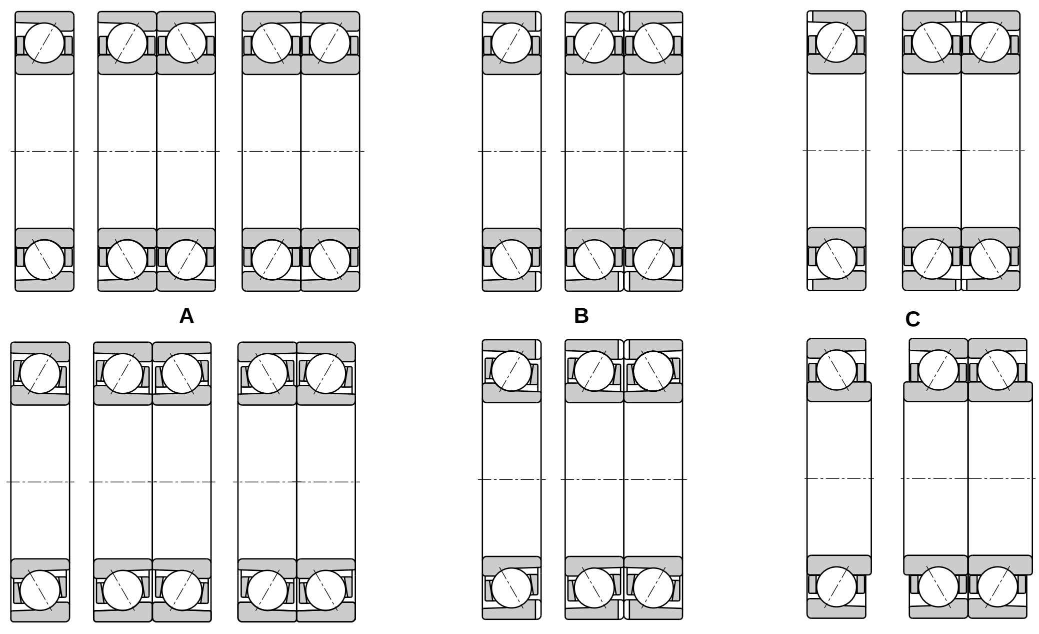

Fig.1 Single row/duplex angular contact ball bearings

1. 2 Double row angular contact ball bearings

Two single row angular contact ball bearings when duplexed back-to-back (DB) so that the inner ring forms one piece are used to create double row angular contact ball bearings. Alternatively, the bearings may be duplexed face-to-face (DF) with the outer ring as one piece.

These bearings support radial and axial loads in either direction: back-to-back duplexed bearings also support moment loads.

The cage type and special shape of the double row angular contact ball bearings are shown in **Fig.2** with the list of drawing numbers in the dimensions table.

The **drawings A** and **B** are the front-to-front duplex arrangement; drawing 2 is a bearing with a lubricating port; **drawings** from **C** to **G** show the back-to-back duplex arrangement and the different position of the lubricating ports whether or not there are lubricating grooves. **Drawing C** shows the inner ring width larger than that of outer ring.

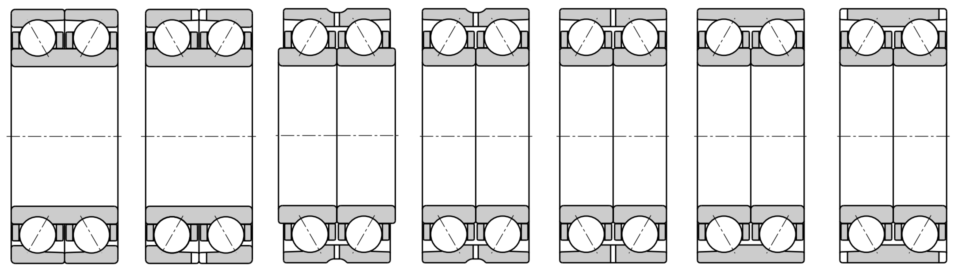

Fig.2 Double row angular contact ball bearings drawing

2. Dimensional Accuracy/Rotation Accuracy

Refer to Table 3.3 (Page A-12)

Single row/Duplex angular contact ball bearings
Double row angular contact ball bearings

3. Recommended Fitting

Refer to Table 4.2 (Page A-24)

Single row/Duplex angular contact ball bearings
Double row angular contact ball bearings

4. Bearing Internal Clearance

Refer to Table 5.3 (Page A-31)

Duplex angular contact ball bearings
Double row angular contact ball bearings

5. Cautions for Operation

When the bearing loads are small(about $F_r \leqq 0.02C_{or}$) or the ratio between the axial and radial loads of the duplex bearing exceeds the value "e", slippage may occur between the balls and the raceways. This slippage may cause smearing. Particularly with large size angular contact ball bearings, this tendency is significant since the ball and cage mass is large. Please consult with **NTN** Engineering for further details.

Cylindrical Roller Bearings

●Cylindrical Roller Bearings

1. Structure and Characteristics

Since the rollers of the cylindrical roller bearings make line contact with the raceways, these bearings can support heavy radial loads and are suitable for high speed operation.

Assembly and disassembly are comparatively easy even if the inner or outer ring requires a shrink fit, as the bearing is a separation type.

Cylindrical roller bearings are classified as single row, double row and four row type, according to how many rollers are used, and there are models as shown in **Table 1** to **3**.

Although designed as a thin wall type, the SL Model double row cylindrical roller bearing can support enormous radial and impact loads. **Table 4** lists the configurations available.

Table 1 Model and characteristics of the single row cylindrical roller bearings

Model code	Drawing	Characteristics
Model NU Model N	 Model NU  Model N	● Model NU has ribs on the outer ring and the inner ring can be separated from "the arranged set of outer ring, rollers and cage". Model N has ribs on the inner ring and the outer ring can be separated from "the arranged set of inner ring, rollers and cage". ● This bearing cannot support axial loads. ● The most suitable model widely used as the free end bearing.
Model NJ Model NF	 Model NJ  Model NF	● Model NJ has ribs on the outer ring and a rib on the inner ring. Model NF has a rib on the outer ring and ribs on the inner ring. ● These bearings support axial loads in one direction only. ● There may be a case to use two bearings adjacent when they are used regardless of the fixed end or free end.
Model NUP Model NH (NJ+HJ)	 Model NUP  Model NH	● Model NUP has a rib ring added on the side of the inner ring where it did not have a rib. Model NJ with the added ring rib of Model L is Model NH. The inner ring should be fixed along the axial direction since each ring rib will be separated. ● These bearings support axial loads in either direction. ● There may be a case to use as the fixed end bearing.

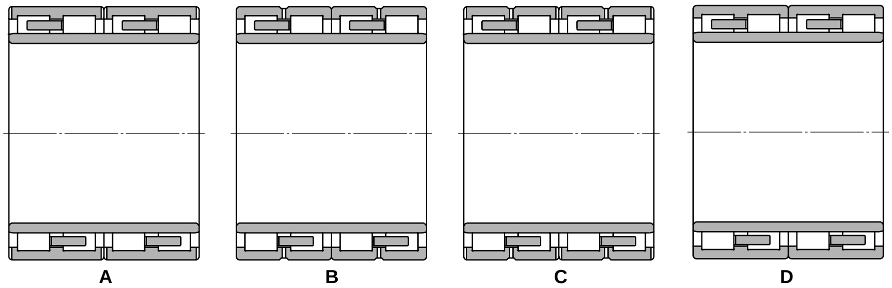
Note: Model E provides higher load capacity designed with increased diameter,length and numbers of rollers but the boundary dimensions are same as the standard type bearings.

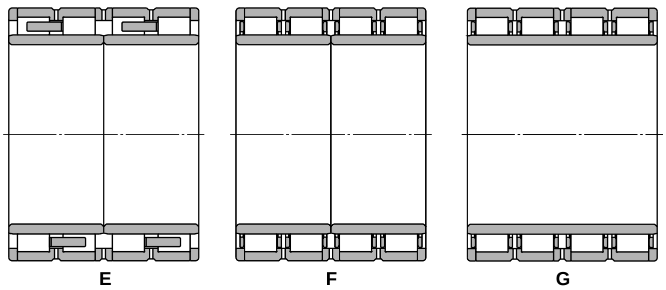
Table 2 Model and characteristics of the double row cylindrical roller bearings

Model code	Drawing	Characteristics
Model NNU Model NN	  Model NNU Cylindrical hole Tapered hole   Model NN Cylindrical hole Tapered hole	● These bearings are used in the main shaft of machine tools, rolling mill rolls and printing machine plate cylinders where thin walled bearings are needed. ● To use the bearing in the main shaft of machine tools, adjust the radial internal clearance by inserting a tapered inner ring to the tapered shaft.

Table 3 Models and characters of four row cylindrical roller bearings

Drawing	Characteristics
Refer to the drawings. **Drawing numbers are listed in the dimensions table.**	● The bearing is mainly used for the roll neck of a rolling mill, and is designed so as to handle the maximum rating load for the allowable space in the roll neck part. Carbonized steel may be used to provide better resistance to cracking or impact to the inner ring. ● Consult **NTN** Engineering about the fitting and bearing internal clearance when the bearing is used for the preparing roll of a rolling mill. ● **NTN** provides bearings with special configurations: with tapered shaft holes; for high speed use; designed to prevent creeping; and, with dust and waterproof seals.





Remarks
Drawings from **A** to **E** show the long cylindrical rollers and the machined cage. **Drawings** from **F** to **G** show the hollow rollers and the pin type cage.

Suffix to the drawing number
M: Bearings which outer ring lubrication port is equipped with a fitting nozzle for oil mist.
R: Inner ring has a helical groove on its inner surface.
S: Special specifications.

Note 1) The bearing has lubricant grooves on both sides of the inner rings.
2) The bearing has lubricant grooves on one of the inner rings.
3) The bearing has lubricant grooves on one of the outer rings.
4) No lubricant groove and hole is designed on the outer ring spacer.

Drawings

Table 4 Model and Characteristics of the Model SL cylindrical roller bearings

Model		Characteristics
Open type	 Model SL01  Model SL02	● Fixed end is Model SL01, free end is Model SL02. ● Since the outer ring is split in the circumference direction using a special method and fixed as a unit after mounting rollers, **the bearing side face should be securely fixed using the shaft or housing shoulder in the axial direction.** ● Outer ring has an oil groove and port. ● Model SL01 can support axial loads from both directions via rollers. ● Shoulder dimensions of shaft and bearings generally applies D_a and d_a dimensions in the dimensions table, but J and K dimensions are used when the moment or large axial loads are applied.
Enclosed type	 Model SL04	● Model SL04 only with the fixed side. ● Since the inner ring is split in the circumference direction using a special method and fixed as a unit after mounting rollers, the bearing side face should be securely fixed by using the shaft or housing shoulder in the axial direction. ● Inner ring has an oil groove and port. ● Model SL04 can support radial and axial loads in either directions. ● A sealed bearing prelubricated with grease, the outer ring is fitted with a locating snap ring, making it easy to handle and appropriate for sheaves and other applications. ● Surface coating is added for rust prevention.

Note: We also provide 3-row, 4-row and 5-row bearings for the Model SL cylindrical roller bearing. Consult **NTN** Engineering for further details.

2. Dimensional Accuracy/Rotation Accuracy

Refer to Table 3.3 (Page A-12,13)

3. Recommended Fitting

Refer to Table 4.2 (Page A-24)

4. Bearing Internal Clearance

Refer to Table 5.5 and 5.6 (Page A-31, 32, 33)

5. Permissible slant angle

It varies according to the bearing type and internal specifications, the values in the table below are widely used to avoid edge loads under general load conditions.

When the width series is 0 or 1 ······0.001 rad (3.5')
When the width series is 2 ············0.0005 rad (1.5')
Double row cylindrical roller bearing ❶ ···0.0005 rad (1.5')

❶ This is no applied to high accuracy bearings which are used as the main shaft of machine tools.

Table 5 Tolerance of inscribed circle diameter F_w of rollers and circumscribed circle diameter E_w of rollers for compatible bearings.

Unit μm

d mm		ΔF_w		ΔE_w	
over	Incl	high	low	low	high
50	120	+ 20	0	0	- 20
120	200	+ 25	0	0	- 25

315	400	140	265	245	370	320	445
400	500	180	320	300	440	395	535

6. Radial internal clearance of the Model SL cylindrical roller bearings.

Table 6 lists the radial internal clearance values of the Model SL cylindrical roller bearings.

7. Recommended fit of the Model SL cylindrical roller bearings, and selection of the radial internal clearance.

Table 7 lists the recommended fit for outer ring rotation such as sheaves and wheels, **Table 8** lists the relation between the fitting and the radial internal clearance.

For assembling and disassembling the bearing, it is necessary to evenly load around the circumference of the raceway end on the fitting side.

8. General Operating Cautions

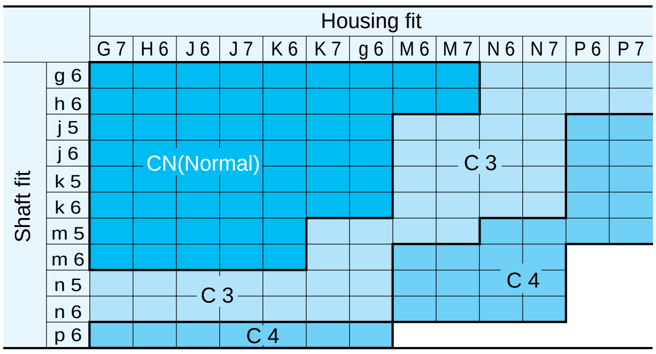
Slippage between the rollers and raceways may occur when bearings are operated under small loads (about $F_r \leqq 0.04C_{or}$) and may cause smearing. This is most apparent when using large size cylindrical roller bearings due to the large cage mass. Please consult **NTN** Engineering for further details.

Table 7 Recommended fit

Conditions		Tolerance range class of shaft	Tolerance range class of housing
Outer ring rotating load	Heavy load with a thin walled housing.	g6 or h6	P7
	Normal load, heavy load		N7 ❸
	Light load, changing load		M7

❸ Be sure to use N7 for sheaves.

Table 8 Relation between fit and radial internal clearance.



Note: When the shaft fit is g6, housing fit is N7(N6) and used at low speed (for sheaves), apply CN(normal) clearance.

Tapered Roller bearings

1. Type, Structure and Characteristics

Tapered roller bearings are designed such that their conical rollers and raceways are arranged so that all elements of the roller and race way cones meet at a common apex on the bearing axis. (Refer to **Fig.1**) The rolling elements perform the real rotating movement on the raceway; the synthesized force from the inner and outer ring raceways guides the rollers, pressing them to the large rib on the inner ring. Metric and inch series are considered standard and both systems are widely used.

The inner ring, rollers and cage can be separated as a unit, or the CONE, from the outer ring, or the CUP. The cup and cone are called sub-units. Sub-unit dimensions for the nominal cup small inside diameter and bearing contact angle, as shown in **Fig. 2**, are standardized by ISO and ABMA and are compatible between sub-units. Double row and four row bearings are available in addition to single row bearings. Models and characteristics are shown in **Tables 1** and **2**.

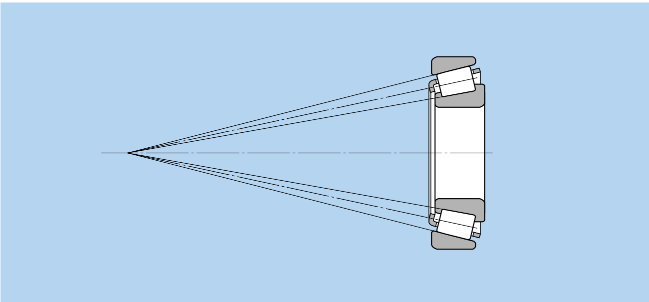

Fig.1

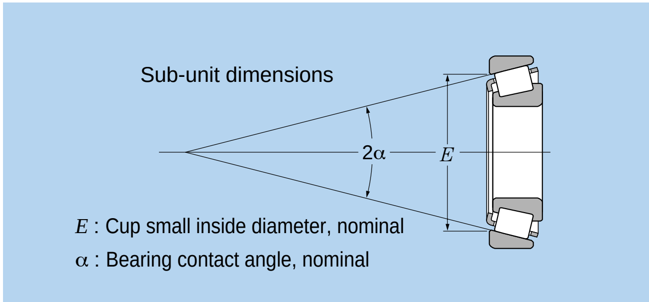

Fig.2

Table 1 Structure and characteristics of double row tapered roller bearings

Model	Drawing	Nominal number	Characteristics
Double row with vertex of contact angles outside of the bearing		413XXX 423XXX 430XXX 432XXX CRI	● These bearings are designed with one double row outer ring and two pairs of inner rings with rollers. Bearings are adjusted so that their internal clearance becomes the specified value, the parts which have the same serial numbers should be assembled according to the assembly codes. ● These bearings support radial and axial loads. Since the cone pressure apex is wide, bearings are suitable where moment loads are applied. ● These bearings have the same function as the back-to-back duplex arrangement of single row bearings.
Double row with vertex of contact steep angles outside of the bearing		CRI	● This bearing model has a larger and steeper contact angle than the double row with vertex of contact angles outside the bearing. These bearings are used when the axial load is large. ● Since these bearings are adjusted so that the internal clearance is a specified value (like the double row with vertex of contact angles outside of bearing) the parts which have the same serial numbers should be assembled according to the assembly codes.
Double row with vertex of contact angles inside of the bearing		3230XX 3231XX CRD	● These bearings are designed with one double row inner ring with rollers and two pairs of outer rings and an outer ring spacer. ● These bearings accept the radial and axial loads. Since the cone pressure apex is short, bearings are not suitable when the moment is applied. ● Since these bearings are adjusted so that the internal clearance is the specified value (like the double row with vertex of contact angles outside of bearing) the parts which have the same serial numbers should be assembled according to the assembly codes.
Double row with vertex of contact steep angles inside of the bearing		CRD	● This bearing model has a larger and steeper contact angle than the double row with vertex of contact angles inside the bearing. These bearings are used when the axial load is large or only axials are applied. ● Models without an outer ring spacer and with a key groove or notch on the inner ring (refer to the drawing) are also available. Consult **NTN** Engineering about this bearing's fit. ● These bearings may be pressurized by using a spring between the housing shoulder and outer ring end.

Table 2 Structure and characteristics of the four row tapered roller bearings

Model	Drawing	Nominal numbers	Characteristics
Four row tapered roller bearing		6259XX 6230XX 6231XX CRO	● These bearings are designed with two double row inner rings with rollers, one double row outer ring, two single outer ring and outer ring spacer/inner ring spacer. Bearings are adjusted so that their internal clearance becomes the specified value, the parts which have the same serial numbers should be assembled according to the assembly codes. ● The bearing is mainly used for the roll neck of rolling mill, and designed so as to become the maximum rating load for the allowable space in the roll neck part. ● The bearing uses the clearance-fit to make assemble and disassembley easier. For this purpose, bearings are designed with a helical groove on the inner ring bore to prevent wearing of the inner ring bore when creep occurs and uses the carbonized steel to prevent cracks on inner ring and improve the shock resistance. ● Please consult with **NTN** Engineering for fitting and bearing internal clearance.
Four row tapered roller bearing enclosed type		CRO···LL	● Bearings are designed with oil seals on both side of the bearing which is the same as the four row tapered roller bearings. ● Please consult with **NTN** Engineering for fitting and bearing internal clearance.

5. General Operating Cautions

Slippage between the balls and raceways may occur when bearings are operated under small loads, or when the ratio between axial and radial loads of the duplexed bearings exceeds the value "e," and may cause smearing. This is most apparent when using large size tapered roller bearings due to the large cage mass. Please consult **NTN** Engineering for further details.

Remarks: 1. With regard to the chamfer dimensions on the back face of the inner and outer rings, installation dimensions r_{as} and r_{1as} are larger than the maximum value.
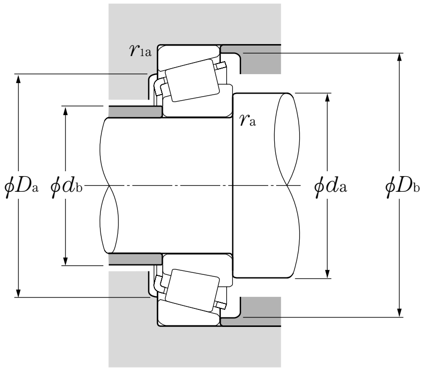
2. Bearing numbers marked "☆" designate bearing with hollow rollers and pin type cages.



Equivalent bearing load
dynamic
$P_r = XF_r + YF_a$

$\frac{F_a}{F_r} \leqq e$		$\frac{F_a}{F_r} > e$	
X	Y	X	Y
1	0	0.4	Y_2

static
$P_{or} = 0.5F_r + Y_o F_a$
When $P_{or} < F_r$ use $P_{or} = F_r$
For values of e, Y_2 and Y_o see the table below.

Remarks: 1. The above chamfer of inner and outer ring are bigger than r_{as} max or r_{1as} max.
2. Bearing numbers marked "☆" designate bearing with hollow rollers and pin type cages.

❶ Minimum allowable dimension for chamfer dimension r or r_1. ❷ This bearing's shape is half of drawing 3 and 4.
Remarks: 1. The marked "∗" bearings are inch system sizes. 2. Bearing numbers marked "☆" designate bearing with hollow rollers and pin type cages.

❶ Minimum allowable dimension for chamfer dimension r or r_1. ❷ This bearing has a screw groove at inner ring's bore and slots at the side face of inner ring.
Remarks: 1. The marked "∗" bearings are inch system sizes. 2. Bearing numbers marked "☆" designate bearing with hollow rollers and pin type cages.

Spherical Roller bearings

1. Type, Structure and Characteristics

The barrel shaped spherical rolling elements of a self-aligning bearing track along two rows of raceway grooves in the inner ring. The center of the outer ring's raceway aligns with the center of the bearing. The self-aligning feature accommodates errors in housing assembly and misalignments between the inner and outer rings caused by bent shafts. The bearings have a large load capacity and are suitable for applications with vibration and impact loads.

In addition to a cylindrical shaft bore, the bearings are available with a tapered shaft bore. The tapered bore bearings can be shaft mounted using an adapter or removable sleeves. **Table 1** shows the types of the self-aligning roller bearings. Please consult with **NTN** Engineering for the special product (do part number starts with 2p)

Table 1 Model of Self-Aligning Roller Bearings

Model	Standard (Model B)	Model C	Model 213
Structure			Bearing Series	Bearings except Model C	24024～24038	213's bore should be more than 55mm.
Roller	A symmetrical roller	Symmetrical roller	A symmetrical roller
Roller guide type	Guided by the inner rib which is united with the inner ring.	By the guide ring located between two rows of rollers.	By the guide ring located between the rollers on the outer ring raceway.
Cage type	Pressed cage Machined cage	Pressed cage	Machined cage

1.2 Lubrication holes and grooves

Holes and grooves to supply lubricant are provided on self-aligning roller bearings with outside diameters greater than 320mm. If required, lubrication holes and grooves can be manufactured for bearings with ODs smaller than 320mm. Consult **NTN** Engineering for further details and add the supplemental code D1 to the part number. **Table 2** shows the dimensions for lubrication holes and grooves. The number of lubrication holes are shown in **Table 3**.

When a knock pin for lubricant retention is necessary, please contact **NTN** Engineering.

Table 2 Lubrication hole and groove dimensions

Nominal bearing outside dia. mm over	incl	Hole number Z_o
—	320	4
320	1,010	8
1,010	—	12

2. Dimensional Accuracy/Rotation Accuracy

Refer to Table 3.3 (Page A-12)

3. Recommended Fitting

Refer to Table 4.2 (Page A-24)

4. Bearing Internal Clearance

Refer to Table 5.10 (Page A-36)

5. Allowable aligning angle

These bearings have a self-aligning function, and their allowable aligning angle varies depending on the dimension series and load conditions, but are mostly described as follows.

Normal load (Equivalent load to 0.09 C_r) ··· 0.009rad (0.5˚)
Light load ······································ 0.035rad (2˚)

6. Assembly of Tapered Hole Roller Bearings

Tapered hole spherical roller bearings use the measurement method as shown in **Fig.1**. A suitable tightening rate can be achieved by pushing the bearing toward the axial direction until it reaches the reduction rate of the radial internal clearance or pushing rate of axial direction. When heavy and high speed loads are applied, or when it is necessary to keep a higher tightening rate as the temperature difference between the inner and outer rings rises, be sure to have the maximum reduction rate of radial internal clearance or the pushing rate of the axial direction, as shown in **Table 4**, by using a bearing with a radial internal clearance of more than C3. The clearance after mounting in this case should be larger than the minimum clearance after mounting as shown in **Table 4**.

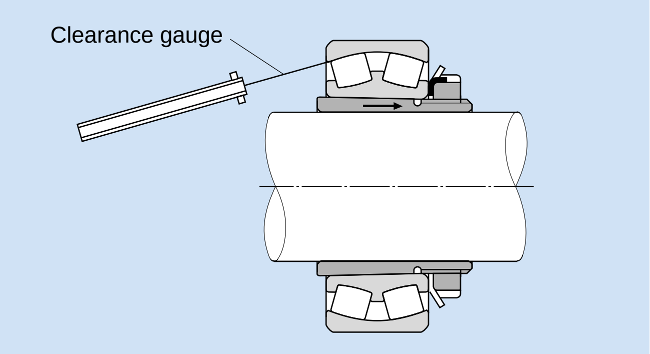

Fig.1 Measurement method of spherical roller bearing internal clearance

7. General Operating Cautions

Pressed cages or machined cages are standard depending on the bearing type and dimensions. However, a standard cage may not be used under high speed specifications or in conditions under severe vibration or impact.

When bearings are operated under small loads (about $F_r \leqq 0.04C_{or}$), or under axial loads only, prevent rolling elements from smearing by operating in conditions where $F_a/F_r \leqq 2e$. (Refer to the dimension table for the value of "e.") This is most apparent when using large size spherical roller bearings due to the large roller and cage mass. Please consult **NTN** Engineering for further details.

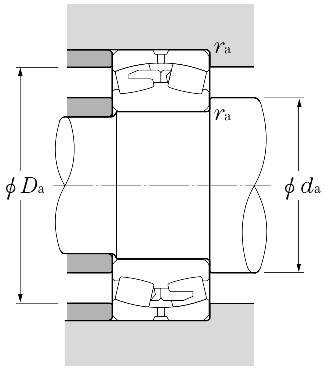
❶ Smallest allowable dimension for chamfer dimension r.
❷ Bearings appended with "**K**" have a tapered bore ratio of 1:12; bearings appended with "**K30**" have a tapered bore ratio of 1:30.
Remarks: 1. Bearing numbers marked "☆" are C type.



Equivalent bearing load

Thrust bearings

1. Classification and Features

1. 1 Thrust ball bearings

Balls are arranged between a set of washers (a shaft washer and housing washer) and the contact angle is 90˚. Axial loads can be supported in only one direction and radial loads cannot be supported. These bearings are unsuitable for high speed operation. **Table 1** shows the standard cage models.

Table 1 Standard cage model

Bearing series	511	512	513	514
Press cage	51120 ～51152	51220 ～51224	51320	—
Machined cage	51156 ～511/750	51226 ～51292	51322 ～51340	51420

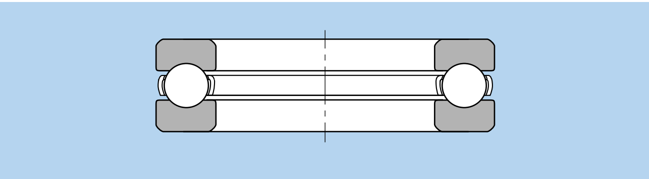

Fig.1 Single type thrust ball bearing (Example of the press cage)

1. 2 Cylindrical roller thrust bearings

These bearings use cylindrical rollers and have single row, double row, 3 row, 4 row, and also duplex types. Bearings can support only axial loads and are suitable to heavy loads. Their axial rigidity is high. Cages are the machined type.

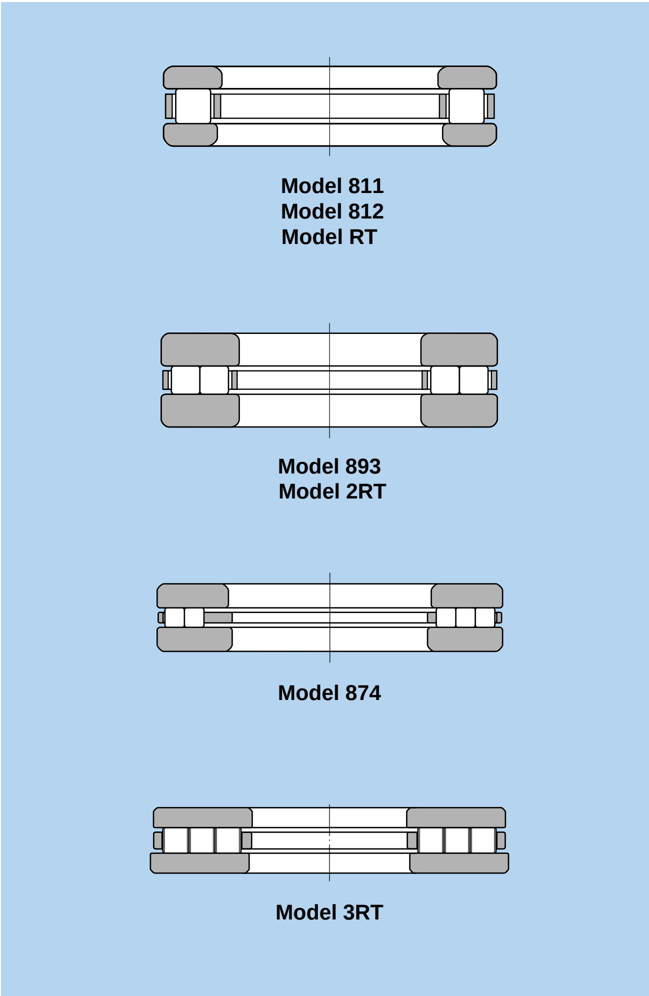

Fig.2 Cylindrical roller thrust bearing

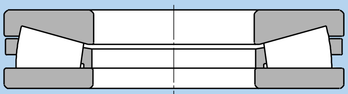
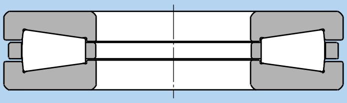
1. 3 Tapered roller thrust bearings

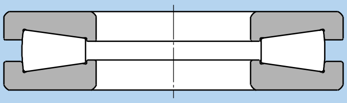
These are thrust bearings using tapered rollers, and the single type bearings have three types of housing washers. One type is the housing raceway with a rib, the other one is without a rib, and the third bearing is the full complement roller type. Double type bearings are mainly used to support axial loads on the roll neck of rolling mill. Machined cages are used for cages.



Drawing 1



Drawing 2



Drawing 3

Fig.3 Tapered roller thrust bearings (Single type)

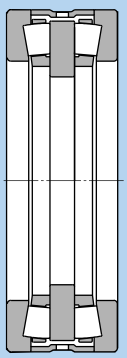


Fig.4 Tapered roller thrust bearings (Double type)

1. 4 Self-aligning thrust roller bearings

These bearings have a self-aligning nature using barrel-shaped rollers. The allowable aligning angle varies depending on the bearing's dimension system, but it is 1˚- 2˚ for normal loads. Cages are machined type and the guide sleeve is on the axial housing raceway. Since the load capacity for axial loads is high, these bearings can support a certain amount of radial load in the instances that axial loads are applied. However, it is necessary to use these bearing where the load conditions meet $F_r/F_a \leqq 0.55$.

These bearings have some spots where lubricant cannot enter such as the gap between the cage and guide sleeve. It is necessary to use oil lubrication even in low speed operation.

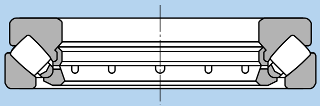

Fig.5 Self-aligning thrust roller bearing

3. Recommended Fitting

Thrust ball bearings
Cylindrical roller thrust bearings
Tapered roller thrust bearings
Self-aligning thrust roller bearings
} **Table 4.3 (Page A-26)**

4. General Operating Cautions

Thrust bearings need to load a certain amount of axial load to prevent sliping between the rolling elements and axial housing raceway. Please consult with **NTN** Engineering for details.

[1] Smallest allowable dimension for chamfer dimension r. [2] Maximum allowable dimension for shaft washer outer dimension d_1. [3] Maximum allowable dimension for housing washer inner dimension D_1. Remarks: Bearing numbers marked "*" signify bearings where the bearing shaft washer outer diameter is smaller than the housing shaft washer outer diameter. Therefore when using these bearings, it is possible to use the housing bore as is, without providing a ground undercut on the outer diameter section of the bearing shaft washer as shown in the drawing.

Contents

Bearings for special applications

Split Cylindrical Roller Bearings: Double–Fractured

- Since the inner ring, outer ring and cage are split in two parts, it is possible to mount the bearing in places where a united bearing is difficult or impossible to mount. (ie. Places where mounting from the shaft end is impossible, an obstacle exists on the shaft, or the shaft is very long.)
- Inspection and maintenance after mounting is easy.

Double–Fractured Split Cylindrical Roller Bearings: Continuous Casting Equipment

NTN

- These bearings are designed to be a full complement roller type and have high rating load for heavy loads, ultra low speed rotation and space-saving.
- These bearings provide a multi-seal with a labyrinth ring, seal ring and special rubber seal to prevent water from invading.
- The clamping ring of the inner ring is not needed anymore and the structure of direct clamping is applied to make a compact bearing.
- Bearings have a self-aligning nature due to the roll deflection since the outer ring outside diameter and the housing inner diameter are spherical.
- Application of a water cooling jacket type housing controls rising bearing temperatures.

❶ Smallest allowable dimension for chamfer dimension r.

- Since bearings are directly used in preparing rolls, the thickness of the outer ring is designed to be thicker than regular bearings.
- Since high accuracy under heavy loads is required, these bearings are designed to have a capacity for heavy loads and high accuracy.
- Several bearings are assembled on one shaft for operation, and the mutual difference of assembled thickness (Dimension H) of bearings on the same shaft is very minimal.
- When the outer ring outside surface is worn, it is possible to recycle it by grinding it to a certain level.

Remarks: 1. The marked "∗" bearings are not prepared with oil holes.

Cylindrical Roller Bearings: Chain Conveyors

NTN

- Since the outer ring directly supports heavy loads, the thickness of outer ring is designed to be thicker than regular bearings.
- For operation under heavy loads and extremely low speed rotation, these bearings are designed to be a full complement roller type and have high loads capacity.
- To prevent foreign matter from entering the bearing, a labyrinth structure is applied, which has a narrower clearance between outer ring and rib ring.

❷ "—" means that is not prepared with a bush.

Tension Leveler Roll Unit: Cartridge Unit

- This unit has a precision small diameter and a long scaled roll, with the surface roughness of the roll designed to be low.
- Angular ball bearings are assembled in multiple rows in the cartridge to obtain high load capacity in both axial directions and at high speed.
- This unit has established both low torque operation and tight sealing by a labyrinth structure and low-contact seals.

- This unit has established both low torque operation and tight sealing by a labyrinth structure and low-contact seals.
- When further low torque is requested, the roll unit (Model BUB), which uses only the deep groove ball bearings, is available.
- Since the unit is used as a backup roll, the accuracy and its surface roughness are designed to be low.

Turn Table Bearings: 3–Row Cylindrical Roller Type

- These are compound type bearings which unite the double row thrust roller bearing and the radial roller bearing.
- These bearings are designed so that rollers in each row support axial and moment loads respectively, and high rigidity and long life can be obtained since the rolling parts make line contact.
- They are suitable for tunnel excavating machines or cranes with frequent turns.

Sealed Spherical Roller Bearings: Model WA

- Special contact type rubber seal prevents foreign matter from entering the bearings.
- Compact design enables bearings to be mounted with the standard type of plummer blocks (SN5, SN2).
- Greasing bearings is possible since lubrication grooves and holes are provided on the outer ring.
- Bearings are prelubricated with grease and can be directly mounted on machines.

Spherical Surface Slide Bearings

- These are self-aligning sliding bearings: the sliding parts form a spherical surface. The bearings also can support radial loads and axial loads in either direction.
- A lubricant (oil or grease) should be used since the sliding parts are steel on steel.
- These bearings are suitable for swinging and aligning movements, and used in joint-movement parts for industrial and construction machines.

〔How to read the table〕 If for example you want to convert 10 kgf to N, find "10" in the middle column of the first set of columns on the right. Look in the N column directly to the right of "10," and you will see that 10 kgf equals 98.066 N. Oppositely, to convert 10 N to kgf, look in the kgf column to the right of "10" and you will see that 10 N equals 1.0197 kgf.

1kgf＝9.80665N
1N＝0.101972kgf

NTN®

EV/HEV用
グリース潤滑高速深溝玉軸受

Grease Lubrication Type High Speed
Deep Groove Ball Bearing for EV/HEV

CAT.No.3040/JE

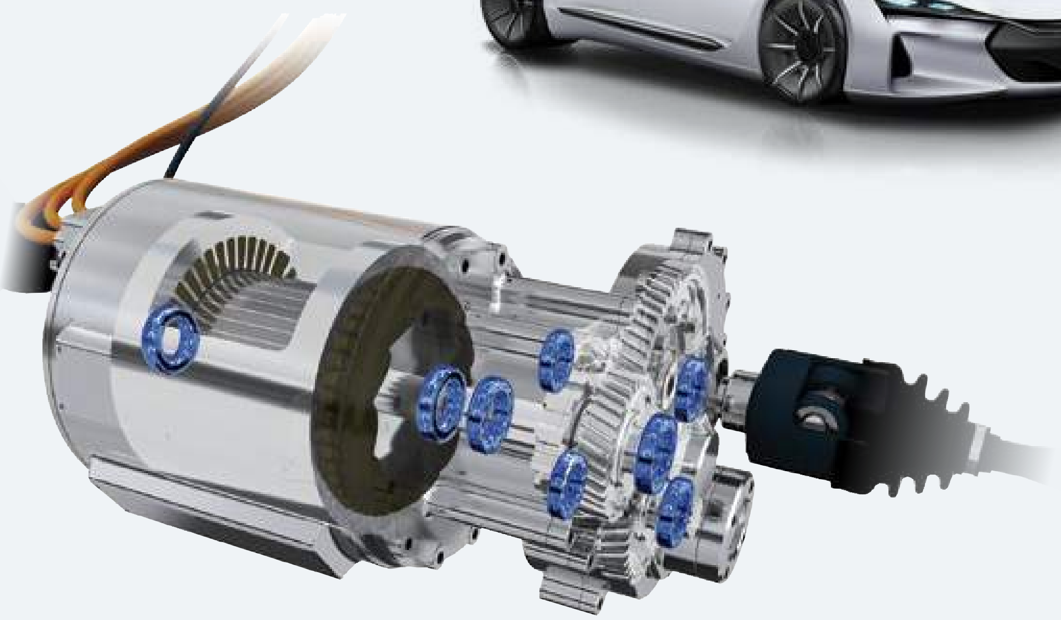
高速性能を向上させた
EV/HEV用高速深溝玉軸受
標準軸受の2倍の許容回転速度を実現

High speed deep groove ball bearing for EV/HEV with improved high speed performance.
Achieves 2X the allowable speed of standard bearings.

軽量高強度樹脂保持器
Lightweight and high strength resin cage

×

高速潤滑性能向上グリース
High speed lubricating performance improved grease



従来のグリース潤滑では、グリースが高速回転により飛び散り、軌道面への供給が不足し、
本来のグリース性能が発揮できません。
EV/HEV用グリース潤滑高速深溝玉軸受は、高速回転用に開発した樹脂保持器とグリースを組み合わせ、
最適なパフォーマンスをご提供します。

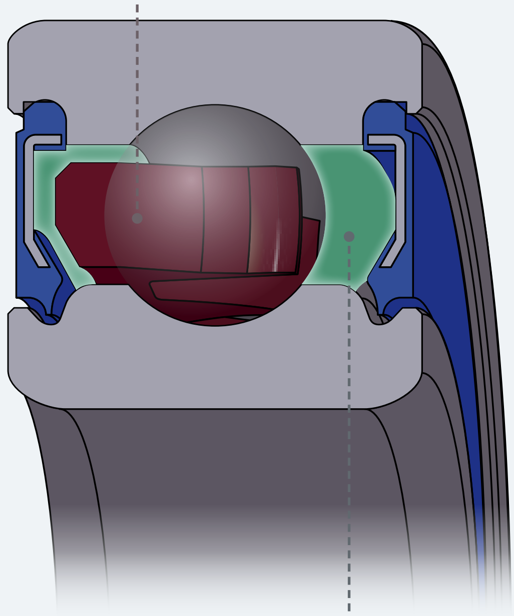
With conventional grease lubrication, high speed rotation causes grease spattering resulting in an insufficient supply of grease to the raceway surface so that the grease is unable to perform as it was originally intended.
Grease Lubrication Type High Speed Deep Groove Ball Bearing for EV/HEV combines a resin cage and grease developed for high speed rotation to provide optimal performance.

特 長　Feature

軽量高強度樹脂保持器
Lightweight and high strength resin cage

高速性・耐熱性・潤滑性を向上させた樹脂材料・形状の採用

Uses a resin material and design with high-speed, heat-resistant and high-lubrication properties



慣性力の低減
Reduced inertial force
- 保持器の軽量化
- Lightweight cage

遠心力変形の低減
Reduced centrifugal force deformation
- 材質と形状の最適化
- Optimized material and design

潤滑性の改善
Improved lubricity
- ポケット形状の改良（グリース溝）グリースを保持し、軌道面への潤滑剤供給を確保
- Improved pocket design (Grease groove) Retains grease and ensures lubricant is supplied to the raceway surface

回転トルク（温度上昇）の低減
Reduced rotational torque (temperature increase)
- 摩擦損失を低減させる形状
- Reduced friction loss design

耐熱性※1 Heat-resistant	材料強度※1 Material strength	遠心力変形※2 Centrifugal force deformation
30 ℃向上 30 ℃ improvement	1.6倍 1.6X	1/8

※1 標準樹脂保持器材料比　Compared with standard resin cage material
※2 標準樹脂保持器比　Comparison with standard resin cage

高速潤滑性能向上グリース
High speed lubricating performance improved grease

広い温度範囲で高い潤滑性と低発熱を発揮するグリースを採用

Uses grease providing high lubricating and low heat generating properties over a wide range of temperatures

潤滑性の改善
Improved lubricity
- グリース成分の最適化により、高速回転時の潤滑性を改善
- Optimization of grease composition improves lubricity during high speed rotation

性 能　Performance

軽量高強度樹脂保持器

高速回転時の遠心力変形を抑制し、高潤滑性、トルク低減、低昇温を可能にする形状と樹脂材料を採用

Lightweight and high strength resin cage

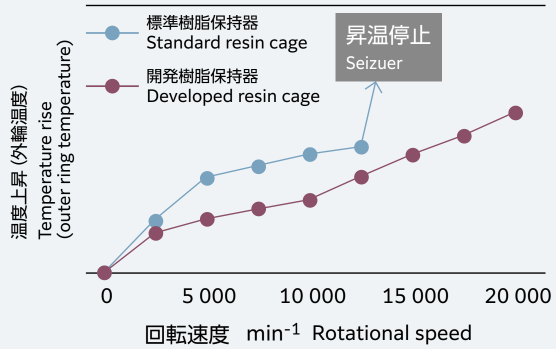
A resin cage is used with a design and resin material that suppress centrifugal force deformation during high speed rotation, which enables high lubricity, torque reduction and low temperature rises

[温度上昇の低減]　[Reduction in temperature rises]

軸受温度上昇比較（樹脂保持器比較）

Comparison of bearing temperature rise for resin cage

軸受寸法 Bearing dimensions	ϕ40×ϕ68×15
雰囲気温度 Ambient temperature	室温 Room temperature

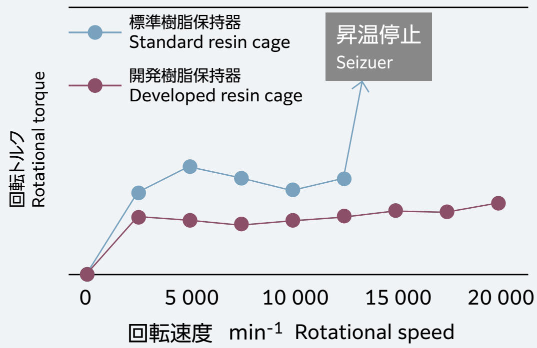


[回転トルクの低減]　[Reduction in rotational torque]

軸受回転トルク比較（樹脂保持器比較）

Comparison of bearing rotational torque for resin cage

軸受寸法 Bearing dimensions	ϕ40×ϕ68×15
雰囲気温度 Ambient temperature	室温 Room temperature

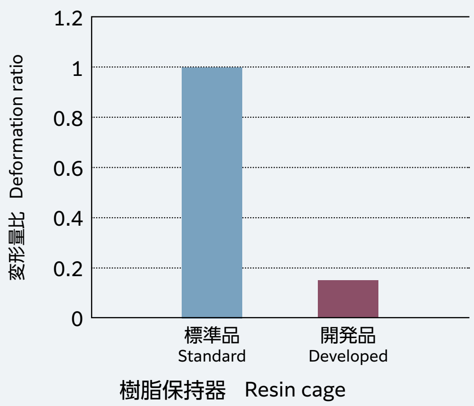


[遠心力変形量の低減]　[Reduction in amount of centrifugal force deformation]

樹脂保持器のポケット先端変形量比較（解析）

Deformation amount comparison of pocket tip on resin cage (Analysis)

軸受寸法 Bearing dimensions	ϕ40×ϕ68×15
回転速度 Rotational speed	20 000min^{-1}
温度 Temperature	120 ℃

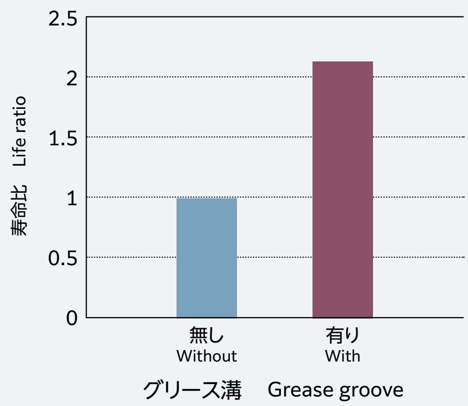


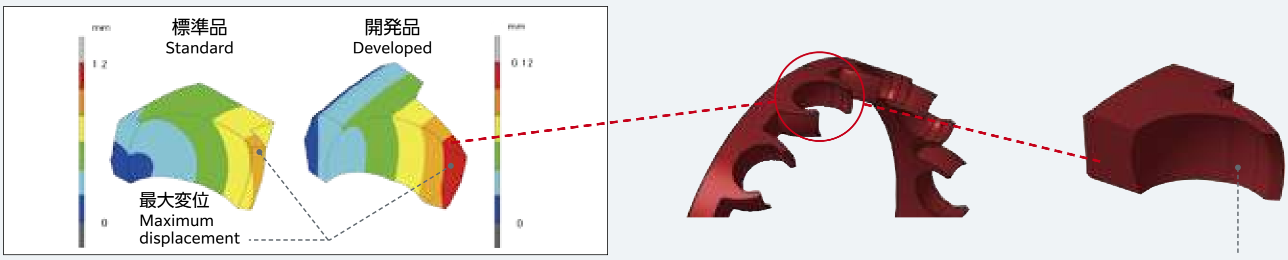
[潤滑性の改善]　[Improvement in lubrication]

グリース溝有無によるグリース寿命比較

Grease life comparison with and without grease groove

軸受寸法 Bearing dimensions	ϕ40×ϕ68×15
回転速度 Rotational speed	20 000min^{-1}
温度 Temperature	120 ℃





保持器ポケット　Cage pocket　　樹脂保持器　Resin cage　　グリース溝　Grease groove

高速潤滑性向上グリース

高速回転時の潤滑性を考慮した組成
高速回転時にもグリース本来の性能を発揮

High speed lubricating performance improved grease

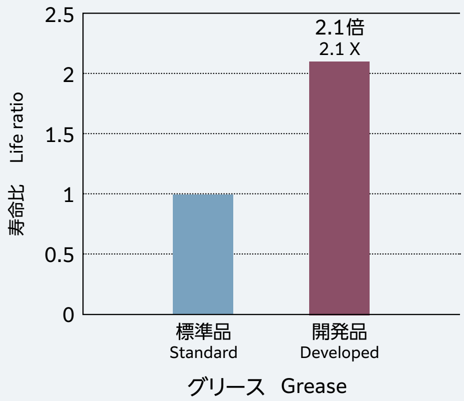
Composition that considers lubricity during high speed rotation
Ensures the original grease performance even during high speed rotation

[潤滑性の改善] [Improvement in lubrication]

グリースの寿命比較（開発樹脂保持器）

Comparison of grease life
(Developed resin cage)

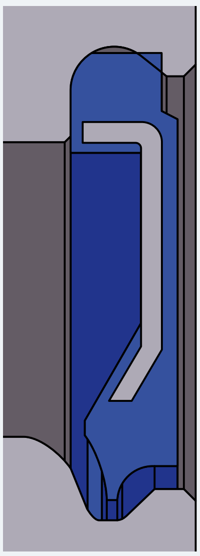
軸受寸法 Bearing dimensions	ϕ40×ϕ68×15
回転速度 Rotational speed	20 000min^{-1}
温度 Temperature	120 ℃



シール

シールは、標準の非接触ゴムシールを採用

標準シール形状を適用しましたが、使用環境や温度によって材質を選定します。



Seal

Uses a standard non-contact rubber seal

This bearing is fitted with a standard-shaped seal. However, NTN selects the material that best suits the environment and temperature in which the bearing is to be used.

※ZZシールドの適用については、**NTN**にご照会ください。

*Please contact **NTN** for ZZ shield applications.

1)ラインアップにない基本番号・主要寸法についても対応可能です。詳細は、**NTN**にご照会ください。
2)疲労限荷重（*Cu*）とは、軌道の最大荷重接触部で疲労限応力となる、軸受にかかる荷重です。軸受の形式、内部諸元、品質、材料強度に依存し、ISO 281:2007では、高清浄度の軸受鋼製軸受において、*Cu*に相当する接触応力として1.5GPaを推奨しています。**NTN**では、標準的な熱処理を施した軸受鋼製軸受について、各呼び番号に対する疲労限荷重の値を寸法表に記載し、寿命修正係数a_{ISO}を適用した修正定格寿命を算出可能としています。詳細については「転がり軸受総合カタログ（CAT.No.2203/J）3.4 修正定格寿命」項をご参照ください。
3)許容回転速度は、軸受温度120 ℃、ラジアル荷重0.05 *Cr*時の目安です。特殊環境下での使用については、**NTN**にご照会ください。

1) We can support basic numbers and boundary dimensions not listed in the product lineup. Please contact **NTN** for details.
2) The fatigue load limit is the applied load on a bearing that results in just reaching the fatigue stress limit at the maximum loaded raceway contact. This depends on the bearing type, internal specifications, quality, and material strength. In ISO 281:2007, 1.5GPa is recommended as the fatigue stress limit corresponding to *Cu* for bearings made of commonly used high quality material and good manufacturing quality. Values for the fatigue load limit with respect to the **NTN** bearing numbers are provided in the dimensional table. The life modification factor, a_{ISO}, should be evaluated considering the fatigue load limit. For details see catalog “Ball and Roller Bearings (CAT.No.2203/E) section 3.4 Modified rating life”.
3) Allowable speed is an estimate when the bearing temperature is 120 ℃ and the radial load is 0.05 *Cr*. Please contact **NTN** for usage in special environments.

減速機などでの使用を目的としたオイル潤滑の適用については、**NTN**にご照会ください。
絶縁を目的としたセラミック玉軸受の適用については、**NTN**にご照会ください。

Please contact **NTN** for oil lubrication applications for use in speed reducers and such items.
Please contact **NTN** for ceramic ball bearing applications for insulation.

耐クリープオプション

Creep resistant option

耐クリープ性を向上させた、AC軸受とEC軸受の2種類の対応が可能

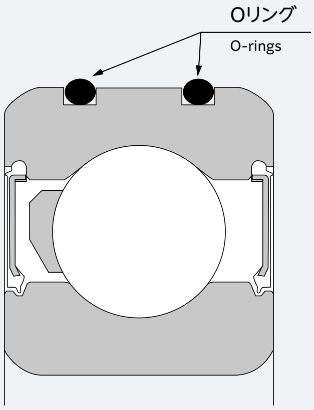
Can support two types, an AC bearing and EC bearing, to improve the creep resistance

【AC軸受】

[AC bearing]

標準の軸受と同じ主要寸法で、外輪外径に設けた二本の溝にOリングを装着した軸受

It has the same boundary dimensions as standard bearings with the addition of two O-ring imbedded on the outside surface of the outer ring



【EC軸受】

[EC bearing]

標準の軸受と同じ主要寸法で、外輪外径に設けた溝に熱膨張率の大きい高分子材料を成形した軸受

Boundary dimensions are same as for standard bearings, but formed polymer material with a high expansion rate is provided in the groove on the outer circumference of the outer ring

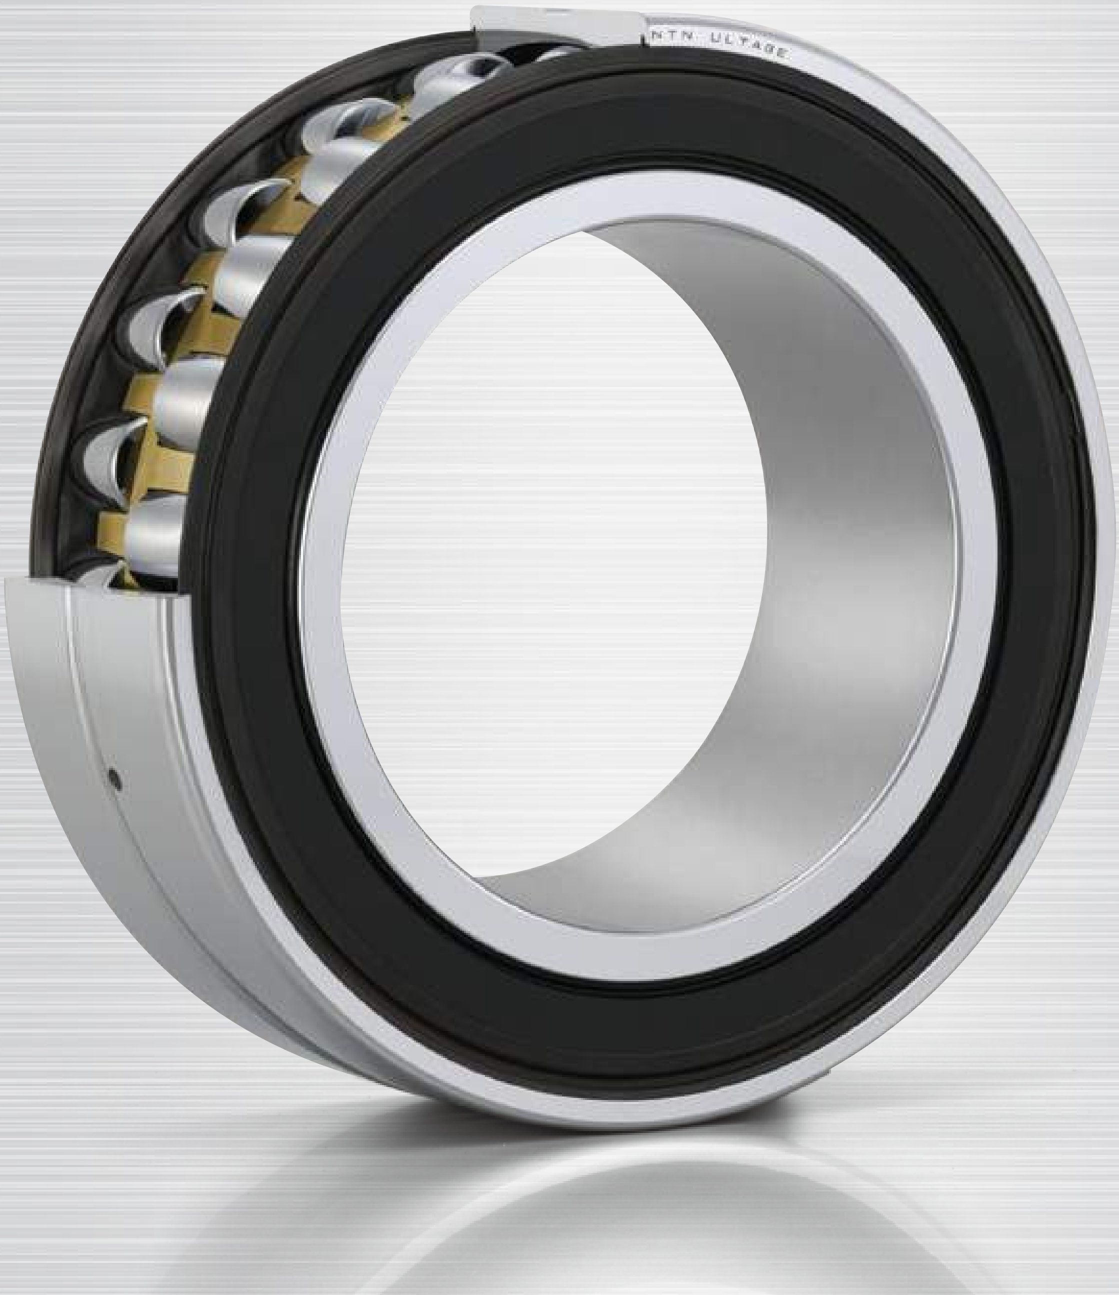
Sealed Spherical Roller Bearings
[EMLLX Type]

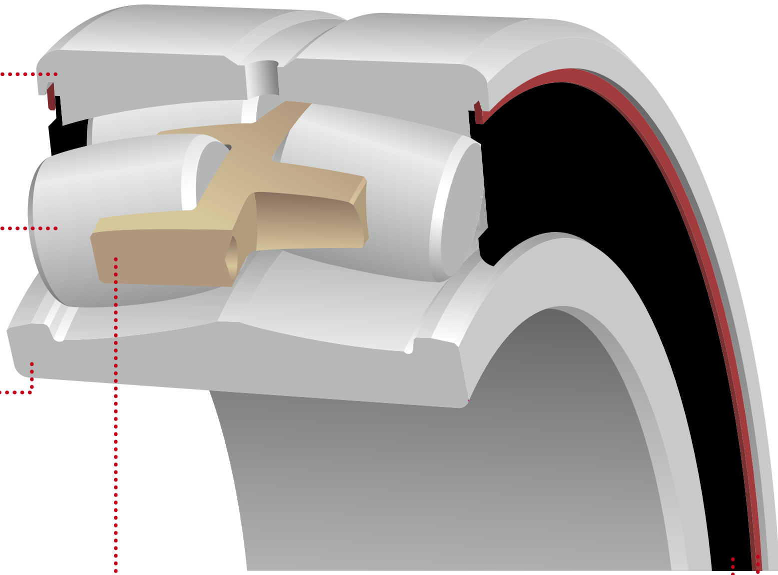
CAT.No.3039-2/E



ULTAGE™

Sealed Spherical Roller Bearings [EMLLX Type]

ULTAGE™ Series Sealed Spherical Roller Bearings (EMLLX Type) are new innovative standard products specifically developed to provide "long life", "higher reliability", and "improved ease-of-use" required for all industrial machineries.



Long Life

- Larger rollers provide the industry's highest load capacity
- Extended maintenance intervals
- Lighter and more compact design

Higher Reliability

- Seals prevent intrusion of foreign matter
- Prolonged relubrication interval

Improved Ease-of-Use

- Uses removable seals
- Complies with ISO dimensions

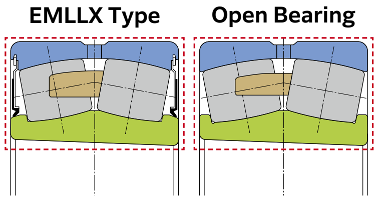
ULTAGE™

"ULTAGE™" (a name created from the combination of "ultimate," signifying refinement, and "stage," signifying NTN's intention that this series of products be employed in diverse applications) is the general name for NTN's new generation of bearings that are noted for their industry-leading performance.

Features

1. Fully Compatible with Open Bearings

The dimensions are the same as open bearings complying with ISO dimensions, so they can replace open bearings without changing the dimensions of the surrounding parts. The allowable misalignment angle of 0.5˚ is also the same between sealed and open spherical roller bearings. (**Fig. 1**)



EMLLX type and open bearings have the same dimensions

Fig. 1

2. Use of Removable Seals

Seals can be removed as they are held in place with a retaining ring. (**Fig. 2**)

- When installing the bearing, the radial internal clearance can be accurately measured with a feeler gauge, and adjusted. (**Fig. 3**)
- The retaining rings can be installed without the use of a special tool, and removed by inserting a flathead screwdriver into the retaining ring notch. (**Fig. 4**)

3. Adoption of Special Thin Seals

- Ensures uniform contact pressure of the seal lip during self-alignment of the bearing, prevention of ingress of foreign matter, and stable sealing.
- Provides sealed spherical roller bearings with the world's largest load capacity.

4. Lubrication Specification in Accordance with Requirements

Either grease-filled type or grease-free type can be selected.

Fatigue Load Limit (C_u)

The fatigue load limit is the applied load on a bearing that results in just reaching the fatigue stress limit at the maximum loaded raceway contact. This depends on the bearing type, internal specifications, quality, and material strength. In ISO 281:2007, 1.5 GPa is recommended as the fatigue stress limit corresponding to C_u for bearings made of commonly used high quality material and good manufacturing quality. Values for the fatigue load limit with respect to the **NTN** bearing numbers are provided in the dimensional table. The life modification factor, a_{ISO}, should be evaluated considering the fatigue load limit. For details see catalog "Ball and Roller Bearings (CAT. No.2203/E) section 3.4 Modified rating life".

❶ Tapered bore ratio 1:12.
❷ Allowable minimum radius for chamfer r.
* For bearing numbers not shown on the 231 Series dimension table (ϕ240 and larger and ϕ420 and smaller), contact **NTN** Engineering.

NTN Standard Grease

- Brand name: Shell Alvania EP Grease 2 (8A)
  High performance grease for heavy duty containing extreme pressure additives.
- Amount of grease: 25 to 35 % of internal free space of the bearing.

Allowable Misalignment

- 0.009 rad (0.5°)

Allowable Rotational Speeds

- dn value ≦6×10[4]
  [dn = Bearing bore diameter d (mm) × rotational speed n (min[-1])]

Allowable Temperature Range

- Bearing temperature: -20 to 110 ℃

Bearing Number

231 36 EM LLX K D1 C3 / 0G V11

Handling Precautions

1.When assembling tapered bore bearings, maintain the reduction in radial internal clearance shown in **Table 1**.
The reduction in radial internal clearance is the difference in the initial clearance and the clearance after assembly.
Note that the axial displacement drive-up in **Table 1** should be taken to be a reference value.

2.During assembly, if misalignment exceeding the allowable misalignment angle (±0.5˚) is applied to the bearing, rollers may come in direct contact with seals causing seal deformation.
Furthermore, if additional force is applied under these conditions, the seals and retaining rings may separate from the bearing, so caution is advised.

3.If a shrink fit is to be used for assembly, do not exceed a bearing temperature of 100 ℃. However, the method of shrink fit by immersion in a hot oil bath cannot be used.

4.The retaining ring can be installed without the use of special tools.
Fit it to the groove in the outer ring sequentially from one end. (**Photo 1**)

5.There is a possibility that the seals or retaining rings will fall out during operation or handling of the bearing, so it is necessary to properly fit the seals and retaining rings.
Confirm the seal and retaining ring are securely fit.

6.After assembly of the bearing, check that there is no slack in the retaining rings.

7.Remove the retaining ring by inserting a flathead screwdriver or similar into the notch of the retaining ring and remove it. (**Photo 2**)

8.When fitting or removing the seals or retaining rings, wear protective glasses for safety, and use caution when handling the retaining rings.
Also, wear gloves during operations with the retaining rings so as not to injure your hand or finger with the tip of the retaining ring.

9.When fitting or removing the seals or retaining rings, be careful not to damage the seals or retaining rings.

10.When supplying grease, the guideline for grease supply pressure is about 0.1 MPa.
If pressure is applied suddenly, there is a possibility that the seals or retaining rings could be dislodged.

11.For the 8AV10 specification, use lithium mineral grease for filling and replenishment. If other types of grease are to be used, please contact **NTN** Engineering.

Sealed Spherical Roller Bearings

[WA Type]

ULTAGE

ULTAGE®

Note: Markings on the seal are not white in actual bearings.

CAT. No. 3703-Ⅱ/E

ULTAGE®

Up to five times longer service life

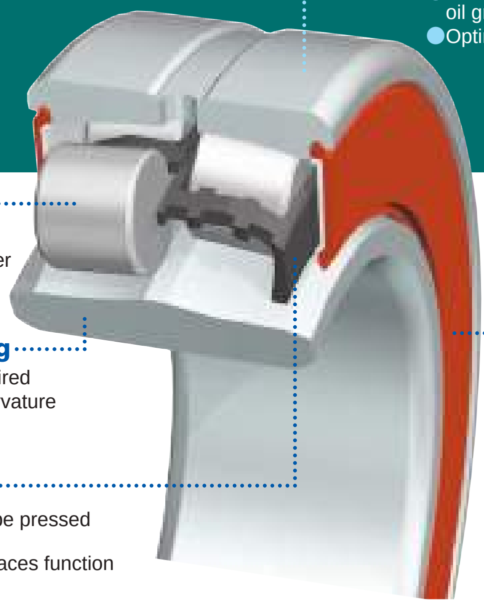
Sealed Spherical Roller Bearings 【WA Type】

ULTAGE Series Sealed Spherical Roller Bearings (WA Type) are new innovative standard products specifically developed to provide “longer service life”, “higher reliability” and “improved ease of use” required for all industrial machineries.

Longer Service Life
- Larger rollers provide the industry’s highest load capacity.
- Extended maintenance intervals
- Lighter and more compact design

Higher reliability
- Prevent from intrusion of foreign matters
- Prolonged relubrication interval

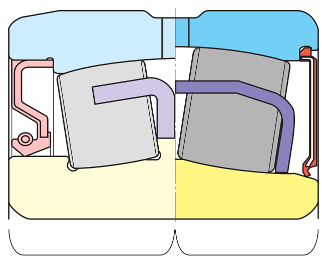
Improved Ease-of-Use
- Unique structure readily accepts lubricant
- Pre-lubricated as standard with long life grease



Features

1. The industry’s highest load capacity

Both a high load capacity and a longer service life are achieved by adopting the internal design of EA type spherical roller bearing which has a significantly increased roller diameter and the maximum number of rollers guided with the window-type pressed steel cage.

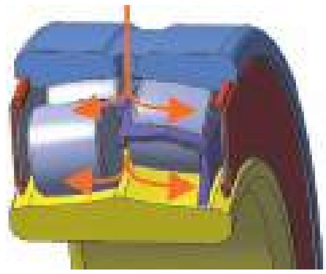


2. Compact design with minimized volume of seals

Adopt the contact type dust-proof seal with minimized volume.
① Prevent from intrusion of foreign matters with uniquely designed contact type rubber seals.
② Secure the dust-proof capability by maintaining the constant contact pressure of seals even under aligned conditions.

3. Prelubricated with a long life grease as standard

Barings are prelubricated with a long life grease.
No cleaning nor greasing are required when being mounted.



4. Oil groove and holes are adopted as standard

Adequate greasing into the inside of the bearing is secured with a lubrication groove and holes on the outside diameter of the outer ring.

ULTAGE®

"ULTAGE®" (a name created from the combination of **"ultimate,"** signifying refinement,and **"stage,"** signifying **NTN**'s intention that this series of products be employed in diverse applications) is the general name for **NTN**'s new generation of bearings that are noted for their industry-leading performance.

❶ Tapered bore ratio of 1:12. ❷ Smallest allowable dimension for chamfer dimension r.

NTN Standard Grease

- Brand name: Shell Alvania EP grease No.2
  High performance grease for heavy duty containing extreme pressure additives.
- Amount of grease: 15～25% of inside free space of the bearing.

Allowable Speed

- With relubrication : $dn \leqq 6\times10^4$
- Without relubrication : $dn \leqq 8\times10^4$

(d= inner bore diameter dimension, mm) × (n= operating speed, min^{-1})

Allowable Misalignment

- 0.009 rad (0.5˚)

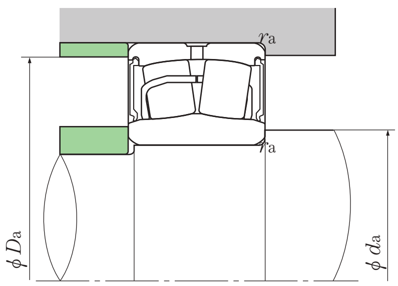
Allowable Temperature Range

- Bearing temperature : -20～+110"

Bearing Number

WA 222 20 EA LLS K D1 C3

- **Seal type code** — WA
- **Dimension series code** — 222
- **Bore diameter code** — 20
- **Type code** — EA — **EA:** Window-type presed steel cage
- **Contact seal on both sides** — LLS
- **Bore configuration code** — K — No code: Cylindrical bore K: Tapered bore
- **Lubrication hole / lubrication groove code** — D1
  - **D1 :** With oil inlet/oil groove (D1 specication only)
  - **W33:** With oil inlet/oil groove (European market specication)
- **Internal clearance code** — C3



Equivalent radial load
dynamic

$P_r = XF_r + YF_a$

$\frac{F_a}{F_r} \leqq e$		$\frac{F_a}{F_r} > e$	
X	Y	X	Y
1	Y_1	0.67	Y_2

static

$P_{or} = F_r + Y_o F_a$

For values of e, Y_1, Y_2 and Y_o see the table below.

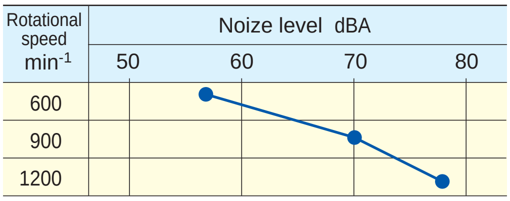
Speed	: 600, 900, 1200min^{-1}
Lubrication	: Shell Alvania EP grease No.2 (**NTN** code 8A)
Amount of grease	: 20% of free space

[Test results]



Grease Leakage Test

[Test conditions]

Bearing	: WA22218EALLSD1
Load	: Radial load 1960N {200kgf}
Speed	: 1000min^{-1}
Lubrication	: Shell Alvania EP grease No.2 (**NTN** code 8A)
Amount of grease	: 20% of free space
Operating time	: 100 hours

[Test results]

Accumulated total amount of grease leakage		
25h	50h	100h
0.47g	0.58g	0.63g

Handling Precautions

1. Because the internal radial clearance of "ULTAGE Series Sealed Spherical Roller Bearings" with tapered bores cannot be measured with a thickness gauge, please monitor clearances by measuring the axial movement of the inner ring as shown in **Table 1**.
2. **During assembly, if misalignment exceeding the allowable misalignment angle of ±0.5˚ is applied to the bearing, rollers may come in direct contact with seals causing seal deformation. Furthermore, if additional force is applied under these conditions, seals may separate from the bearing entirely. Therefore, caution is advised.**
3. Please use Lithium mineral grease. In case other types of grease are to be used, please consult **NTN**.
4. **If a shrink fit is to be applied, please do not exceed a bearing temperature of 100˚C. However, these bearing cannot be shrink fit via immersion in a hot oil bath.**

Table 1 Installing sealed tapered bore bearings

Nominal bore diameter *d* mm		Reduction in radial internal clearance		Axial displacement drive-up		Minimum residual internal clearance

HK-F Type Drawn Cup Needle Roller Bearings

プレミアムシェル™軸受

CAT.No.3029-2/JE

CAT.No.3029-2/JE 23.01.005 DS/DS

The Next Generation of Drawn Cup Needle Roller Bearings

HK-F type drawn cup needle roller bearings

次世代のシェル形針状ころ軸受 プレミアムシェル™ 軸受

Advantages of HK-F type drawn cup needle roller bearings

(Compared with current standard drawn cup needle roller bearings)

プレミアムシェル™ 軸受の特長

〈現行標準仕様 シェル形軸受との比較において〉

■Service life: Three times longer

■寿命向上：3倍

■Allowable static load: 1.5 times greater

(Safety factor: current products, $S_0≧3$; HK-F type, $S_0≧2$)

■静的許容荷重向上：1.5倍

（安全率　現行標準品：$S_0≧3$　プレミアムシェル™ 軸受：$S_0≧2$）

■Reduction and stabilization of press fit force

Bearings can be press fit from either side thanks to manufacturing by the "Pre-bent"production method

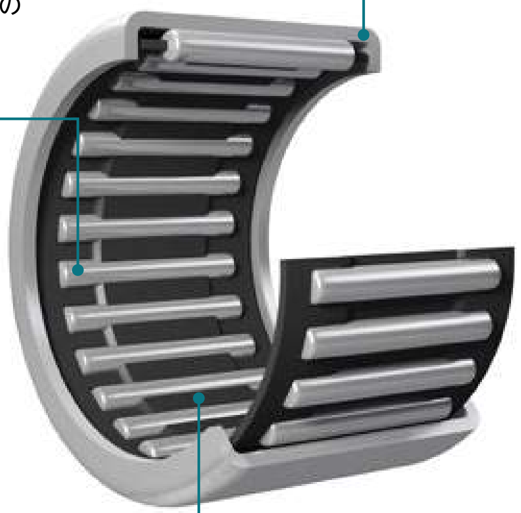
■圧入力低減と安定化

プリ・ベント仕様品については組込方向性なし

1. Bearing specifications 軸受仕様

NTN optimized the specifications of every bearing component in order to develop a new series of long-life drawn cup needle roller bearings.

すべての部品に対する最適仕様を追求し、長寿命化ニーズに対応したシェル形針状ころ軸受の新シリーズが誕生しました。



Rollers ころ

Special heat treatment

NTN has adopted a special heat treatment (specialized carbonitriding) as its new standard.
This special heat treatment provides proven results in extending service life.

特殊熱処理の採用

長寿命化において多くの実績を持つ、特殊熱処理（特殊浸炭窒化処理）を標準仕様としています。

Crowning

Stress concentration at the roller ends (edge load) caused by assembly misalignment and heavy load is reduced.
This innovation contributes to extended bearing life.

クラウニングの採用

取付誤差、重荷重により生ずるころ端部の応力集中（エッジロード）を緩和し、寿命向上に貢献します。

Cage 保持器

V-form cage

The flow of lubricant to and from the inside of the bearing has been improved. At the same time, NTN has adopted a V-form cage design to ensure roller stability, thus extending bearing life.

V形状を採用

軸受内部への潤滑油の流入・流出を向上させ、さらに運転中のころの安定挙動が可能となるV形状を採用することで寿命向上に貢献します。

Case-hardened and tempered or soft-nitrided

The cage is case-hardened and tempered or soft-nitrided to enhance wear resistance and mechanical strength.

浸炭焼入れ または 軟窒化

保持器の耐摩耗性と強度の向上を図っています。

Outer ring 外輪

Carburized chrome molybdenum steel

The higher internal hardness resists permanent deformation from static load. As a result, HK-F type drawn cup needle roller bearings can be used under static load conditions with a safety factor of $S_0≧2$, a significant improvement over the $S_0≧3$ safety factor of current standard drawn cup needle roller bearings.

クロムモリブデン鋼の浸炭焼入れ

内部硬度の向上により静的荷重による永久変形を抑えることで従来の安全率 $S_0≧3$に対して $S_0≧2$の静的重荷重条件下での使用を可能にしました。

Optimal outer ring shape including optimized chamfers and outer diameter surface

The optimized shape contributes to smooth press-fitting of the bearing into the housing.
This arrangement greatly simplifies the press-fitting process on an automatic assembly line.

外径母線形状の最適化、チャンファ形状の最適化

形状の最適化でスムーズなハウジングへの圧入を実現しました。自動組立ライン等での圧入作業の効率化に貢献します。

Redesigned rib

NTN has introduced a rib with a larger bore diameter to promote the flow of lubricant into the bearing from outside.

鍔内径寸法の変更

軸受外部からの潤滑油の流入を容易にするため、鍔内径寸法を大きくすることで、軸と鍔内径間のすきまを十分に確保しました。

Other features その他

"Pre-bent" production method (Only for some HK-F type drawn cup needle roller bearings)

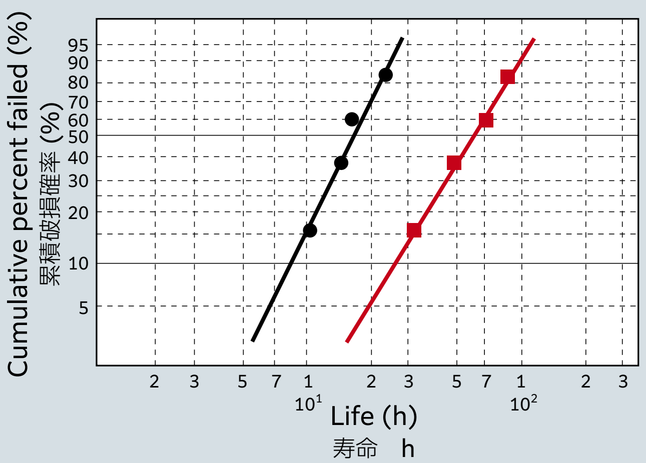
The "Pre-bent" production method results from an unconventional manufacturing process. In this process, the rollers and cage are first assembled into the outer ring and the bent edge rib is bent prior to heat treatment. This gives the rib (at the bent edge side) the same hardness as the remainder of the outer ring.
At the same time, this development eliminates the conventional limitation that the bearing must be press-fit with a jig placed on the marked side face.
This allows the bearing to be press-fit in either direction.
Additionally, optimal heat-treatment contributes to longer bearing life.

プリ・ベント仕様の採用（一部対象外）

プリ・ベント仕様とは、従来と異なる製造方法です。
外輪の熱処理前に保持器付き針状ころを挿入して、外輪の縁曲げを行ったあとに熱処理を実施するため、両側の外輪鍔硬さが確保されます。このことで、刻印側、非刻印側のいずれの方向からでも圧入が可能となりました（従来品は、鍔硬さが確保されている刻印側から治具を当てて圧入）。さらに、熱処理の最適化で寿命向上にも貢献します。

2. Test data 試験データ

1) Life test 寿命試験

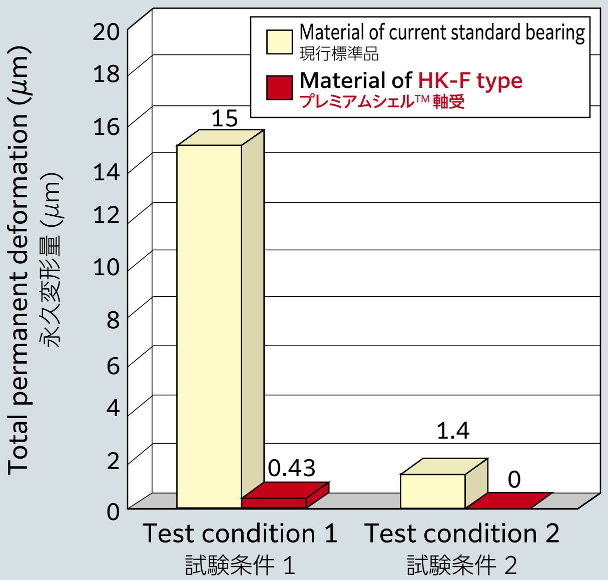


● Current standard product 現行標準品
■ HK-F type プレミアムシェル™ 軸受

Test bearing: (Current) HK2216C (HK-F type) HK2216F
Test load: 6.82 kN《approx. 0.5 C》
Rotating speed: 10 000 min^{-1}
Lubricating oil: Turbine oil 46
Lubrication system: Circulating oil

試験軸受：(現行) HK2216C (プレミアムシェル™ 軸受) HK2216F
試験荷重：6.82 kN《約 0.5C》
回転速度：10 000 min^{-1}
潤　　滑：タービン#46
潤滑方法：循環給油

2) Static load test of outer ring material 外輪材質の静的強度試験



Test condition	1	2
Contact stress GPa	3.9	3.4
Equivalent safety factor S_0	1.5	2
Test plate	t = 1 mm flat	
Rollers	ϕ3×7.8, crowning	

試験条件	1	2
接触応力 GPa	3.9	3.4
安全率 S_0 換算	1.5	2
試験片	t = 1 mm 平板	
使用ころ	ϕ3×7.8, クラウニング付き	

3. Effect of crowned rollers (calculated values) ころクラウニングの効果(計算値)

The HK-F type drawn cup needle roller bearing has crowned rollers. Crowning reduces the stress concentration at the roller ends (indicated by round symbols within the diagram at right) caused by heavy load.

プレミアムシェル™ 軸受ではころへのクラウニング加工を標準仕様とすることで、重荷重条件下で現行標準品使用時に発生するころエッジ部の応力集中(右図丸印部)を緩和しています。

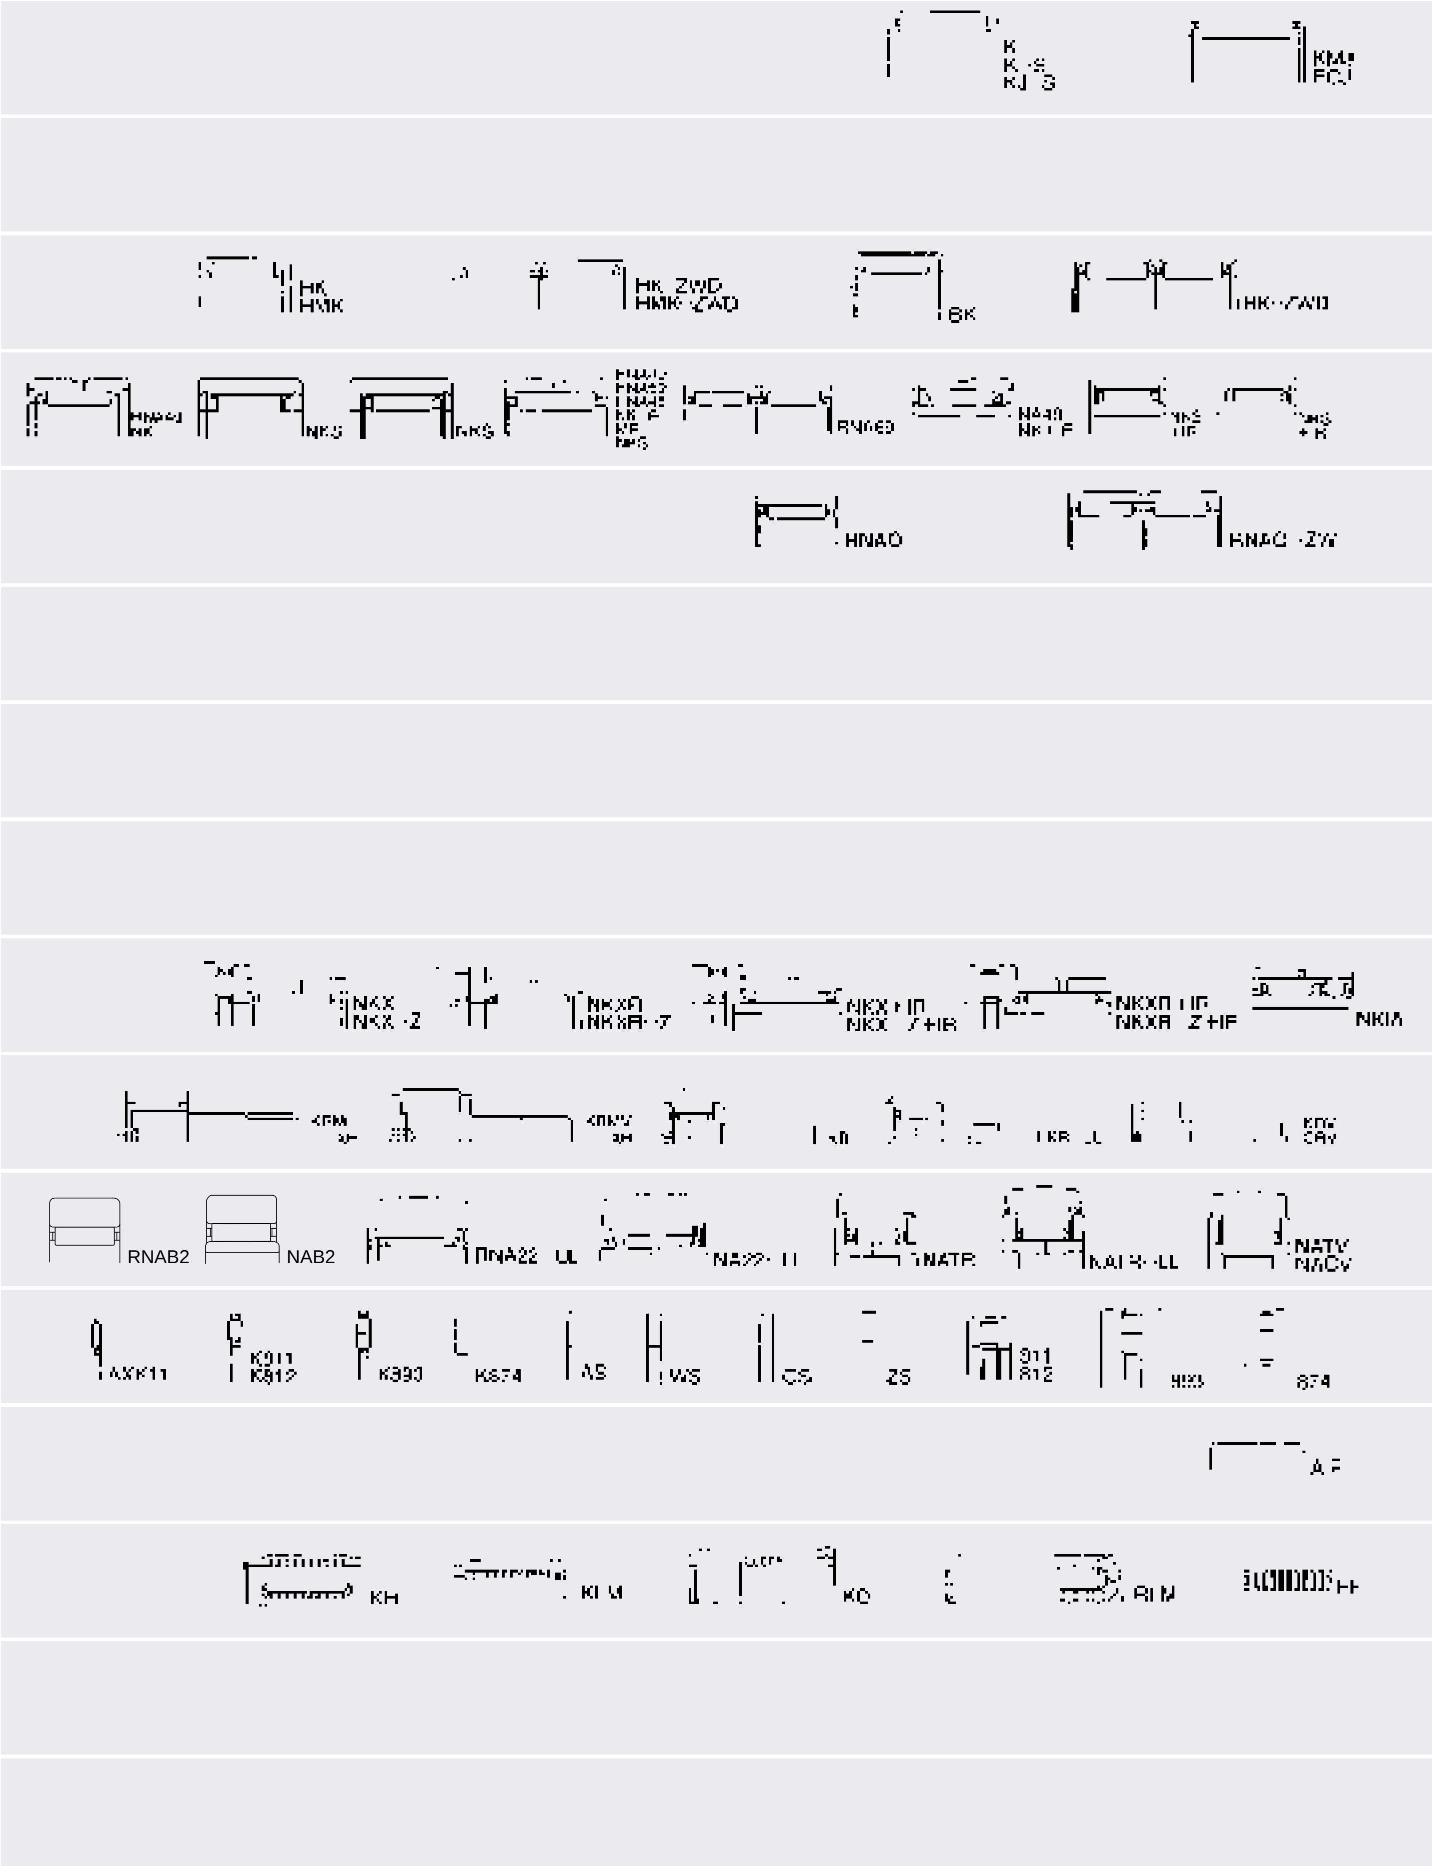
Needle Roller Bearings

CAT. NO. 2300-X/E

CONTENTS



Warranty

NTN warrants, to the original purchaser only, that the delivered product which is the subject of this sale (a) will conform to drawings and specifications mutually established in writing as applicable to the contract, and (b) be free from defects in material or fabrication. The duration of this warranty is one year from date of delivery. If the buyer discovers within this period a failure of the product to conform to drawings or specifications, or a defect in material or fabrication, it must promptly notify **NTN** in writing. In no event shall such notification be received by **NTN** later than 13 months from the date of delivery. Within a reasonable time after such notification, **NTN** will, at its option, (a) correct any failure of the product to conform to drawings, specifications or any defect in material or workmanship, with either replacement or repair of the product, or (b) refund, in part or in whole, the purchase price. Such replacement and repair, excluding charges for labor, is at **NTN**'s expense. All warranty service will be performed at service centers designated by **NTN**. These remedies are the purchaser's exclusive remedies for breach of warranty.

NTN does not warrant (a) any product, components or parts not manufactured by **NTN**, (b) defects caused by failure to provide a suitable installation environment for the product, (c) damage caused by use of the product for purposes other than those for which it was designed, (d) damage caused by disasters such as fire, flood, wind, and lightning, (e) damage caused by unauthorized attachments or modification, (f) damage during shipment, or (g) any other abuse or misuse by the purchaser.

THE FOREGOING WARRANTIES ARE IN LIEU OF ALL OTHER WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE.

In no case shall **NTN** be liable for any special, incidental, or consequential damages based upon breach of warranty, breach of contract, negligence, strict tort, or any other legal theory,and in no case shall total liability of **NTN** exceed the purchase price of the part upon which such liability is based. Such damages include, but are not limited to, loss of profits, loss of savings or revenue, loss of use of the product or any associated equipment, cost of capital, cost of any substitute equipment, facilities or services, downtime, the claims of third parties including customers, and injury to property. Some states do not allow limits on warranties, or on remedies for breach in certain transactions. In such states, the limits in this paragraph and in paragraph (2) shall apply to the extent allowable under case law and statutes in such states.

Any action for breach of warranty or any other legal theory must be commenced within 15 months following delivery of the goods.

Unless modified in a writing signed by both parties, this agreement is understood to be the complete and exclusive agreement between the parties, superceding all prior agreements, oral or written, and all other communications between the parties relating to the subject matter of this agreement. No employee of **NTN** or any other party is authorized to make any warranty in addition to those made in this agreement.

This agreement allocates the risks of product failure between **NTN** and the purchaser. This allocation is recognized by both parties and is reflected in the price of the goods. The purchaser acknowledges that it has read this agreement, understands it, and is bound by its terms.

NTN

Needle Roller Bearings

TECHNICAL DATA CONTENTS

DIMENSIONAL DATA CONTENTS

1. Classification and Characteristics of Needle Bearings

Needle roller bearings have relatively small diameter cylindrical rolling elements whose length is much larger than their diameter.

Compared with other types of rolling bearings, needle roller bearings have a small cross-sectional height and significant load-bearing capacity and rigidity relative to their volume. Also, because the inertial forces acting on them is limited, they are an ideal choice for applications with oscillating motion. Needle roller bearings also work well in compact and lightweight machine designs and they serve as a ready replacement for sliding bearings.

NTN offers several different types of needle roller bearings.

Needle roller and cage assembly

A needle roller and cage assembly includes needle rollers and a cage that guides and retains the rollers.

- These assemblies use both the shaft and housing as raceway surfaces. Consequently, the cross-sectional thickness of the assembly is small, roughly equivalent to the diameter of the needle rollers.
- Because this bearing type has no inner or outer rings, the installation is much easier.
- These assemblies are available in both single-row and double-row configurations.
- As long as the tolerance limits of the shaft and housing are satisfied, the bearing radial internal clearance can be adjusted.

Needle roller and cage assembly for connecting rods

A needle roller and cage assembly for connecting rods includes needle rollers and a cage that guides and retains rollers. This bearing type is used for connecting rods in compact and mid-sized internal combustion engines (e.g. outl engines and multipurpose engines), as well as reciprocating compressors.

Needle roller and cage assembly for large end

- This product boasts a unique light-weight high-strength design to cope with crank motion involving the simultaneous rotation and revolution on the large-end side of connecting rod. At the same time, the outer diameter of the cage surface is precision-finished so that the assembly maintains the appropriate cage-riding clearance.
- The cage is made of high-tensile special steel with a surface hardened treatment.
- The assembly uses an outer diameter-guided system.
- If an application has poor lubrication, the cage can be protected with a surface treatment using a non-ferrous metal.
- For applications with a one-piece crank shaft, split-type cage design is also available.

Needle roller and cage assembly for small end connecting rods

- The small end of connecting rods are subjected to high impact loads and high-speed oscillation. To address this condition, these bearings boast a unique light-weight high-strength design. In addition the cage bore surface is precision-finished so that the assembly maintains an appropriate cage-riding clearance.
- The cage is made from high tensile special steel and the cage surface is hardened.
- The cage is bore-guided and the guide surface is designed to be as long as possible to minimize surface pressure.
- Rollers with the longest possible length are used, At the same time, the maximum number of smaller diameter rollers are incorporated in order to reduce the contract pressure on the rollers.

Drawn-cup needle roller bearing

This bearing type includes an outer ring and needle rollers, which are both drawn from special thin steel plate by precision deep drawing, and a cage which guides the needle rollers precisely.

- This bearing product comprises an outer ring formed through precision deep-drawing process from a thin special steel blank; needle rollers; and cage that guides the rollers.
- A hardened and ground shaft or inner ring (IR Series) is used as the raceway.
- This bearing needs no axial clamping due to easy installation and a press-fit in the housing.
- Both a closed end type to close around the end of the shaft and an open end type are available.
- Furthermore, a type with a seal installed on a single side or on both sides is also available.
- The standard type includes a needle roller and cage assembly. In addition to this type, a special type with full complement rollers is available as an option.

Machined-ring needle roller bearings

This product mainly includes machined components — an outer ring and inner ring, needle rollers and a cage that guides the rollers. In this bearing, the cage or needle rollers are guided by the rib or side plate of the outer ring. Consequently, the roller and cage assembly cannot be separated from the outer ring. When the user wants to use the shaft as the raceway surface, NTN can offer a variant without an inner ring.

- Available in both metric dimensions and inch dimensions.
- This product is best-suited to a space-saving design due to its low section height,and large load capacity.
- Another advantage is high rigidity and high bearing accuracy due to the machined outer ring
- This bearing can be used with a housing made of light metal, because of its highly rigid outer ring. (Other than NKS small size products)
- The outer ring has a lubrication hole and lubrication groove.
- Both single-row and double-row types are available.
- A type with seal a installed on a single side or on both sides is also available.

Machined-ring needle roller bearing separable type

This product is essentially comprised of a machined outer ring, inner ring, and, needle rollers with a cage to guide the rollers. With this bearing, the roller and cage assembly can be separated from the outer ring. If the user wants to use the shaft directly as a raceway surface, NTN offers a variant that lacks inner ring.

- Easy to install: The following components can be mounted independently: cage and roller assembly, and the inner and outer rings.
- Radial Internal Clearance: Radial internal clearance is selected by combining individual independent components with the desired clearance.
- Space Saving Design: Best-suited to save space because of its low section height and large load capacity.
- High Rigidity: The machined (precut) outer ring allows the bearing to have high rigidity and high bearing.
- Housing Material: This bearing can be mounted in light alloy metal housings because of the outer ring high rigidity.
- Single and double row types bearings available. The outer ring of the double row bearing has a lubrication hole and groove.

Inner ring

Most needle roller bearings lack an inner ring and use the shaft as raceway surface. However, there may be cases where the shaft surface cannot be changed on the machine to the required hardness and/or roughness so in this case an inner ring may be used. NTN inner rings are made of high carbon chromium bearing steel blank that is heat-treated, and then fInish-ground to higher precision.

- Can also be used as a bushing.
- Available in both metric and inch series.
- Lubrication hole type at the raceway center is also available.

Clearance-adjustable needle roller bearing

This product is essentially comprised of a machined outer ring, inner ring, and, needle rollers with a cage to guide the rollers. This product features an outer ring with a unique cross-sections shape machined from a solid blank material. With this bearing, the roller and cage assembly cannot be separated from the outer ring. If the user wants to use the shaft directly as a raceway surface, NTN offers a variant that lacks inner ring.

- Clearance Reduction: The outer ring raceway diameter is reduced by clamping the outer ring axially,which then reduces the roller assembly bore diameter.
- Clearance Adjustment: Axial clamping force on the bearing can be adjusted to alter the reduction on outer ring raceway diameter.
- Application: This bearing is used on machine tools main spindle and other similar applications which require high speed rotational accuracy of JIS Grade-4.

Thrust roller bearing

The product is comprised of needle or cylindrical rollers, a cage that guides and retains the rollers, and a disk shaped bearing ring, and is capable of holding an axial load in one direction. The mounting surface can be used as raceway surface when the mounting surface are beat-treated and finished. As a result, the bearing can be supplied without bearing ring raceways.

- Space Saving Design: Best-suited to save space because of its small section height and large load capacity.
- Bearing Types: Current available bearing ring types are AS, WS, GS, and ZS. The AS type consists of a thin steel disk having undergone surface-hardening, while the WS, GS and ZS types are machined.

Complex needle roller bearings — Needle roller bearing with thrust bearing —

This complex bearing is comprised of a needle roller bearing for supporting radial load and a thrust bearing for supporting axial load which are assembled integrally. Both thrust ball bearing and thrust roller bearing type are available to support axial load.

- A variant of thrust bearing are equipped with a dust cover that positively prevents outward release of oil splash and protects the bearing against ingress of dust.

Complex needle roller bearings
— Needle roller bearing with angular contact ball bearing, needle roller bearing with three-point contact ball

This complex bearing is comprised of a needle roller bearing for supporting radial load, a ball bearing for supporting comparatively small axial load and machined inner and outer rings which are all assembled integrally. Both angular contact ball bearing and three-point contact ball bearing are available to support the axial load.

- The complex needle roller bearings (NKIA Series) use an angular contact ball bearing as the thrust bearing to support a one-directional axial load.
- The complex needle roller bearings (NKIB Series) use a three-point contact ball bearing as the thrust bearing to support a double-directional axial load in addition the position in axial direction can be fixed.

Needle roller bearing with double thrust roller bearing

This is a complex bearing wherein a thrust needle roller bearing or a thrust cylindrical roller bearing intends to support an axial load is configured at the double sides of a radial needle roller bearing for supporting radial load.

- Bi-Direction Axial Loading: This bearing can support large axial loads from both sides.
- Application: This complex bearing is designed to support a machine tool precision ball screw.

The track roller bearing is a needle roller bearing with thick outer ring, which is applied to cam roller, guide roller, eccentric roller or rocker arm.

The track roller bearings are mainly categorized into a stud type track roller bearing (cam follower) and a yoke typ roller bearing (roller follower). Various types of the roller follower and the cam follower are available.

Cam follower Needle roller type —

This is a bearing designed for rotation of the outer ring. A needle roller and cage assembly and a stud instead of inner ring are fitted in the thick-walled outer ring. The stud is threaded to be mounted easily. This cam follower (bearing) uses needle rollers as its rolling element and it is available with cage or full complement roller bearing type without cage.

- The bearing type with cage is suitable to comparatively high speed running because its rollers are guided by the cage.
- Having more rollers relative to a given size, a full complement roller type boasts greater load capacity.
- The outer surface is available in both spherical (crowning) profile and cylindrical profile.
- This cam follower (bearing) is selectively available is both metric and inch sizes.
- A seal built-in type is also available.
- The stud is either a recessed head type allowing use of a screwdriver or hexagon socket head type so as to be mounted and adjusted easily.

Cam follower —Cylindrical roller type —

This is a full complement roller bearing designed for rotation of the outer ring. Double-row cylindrical rollers and a stud instead of inner ring are fitted in the thick-walled outer ring. The stud is threaded be mounted easily.

- Compared with needle roller type of a given size, cylindrical roller type of a similar size boasts greater load capacity.
- A steel plate is press-fitted in the outer ring and a labyrinth seal is formed between the face ring and the outer ring.
- The outer surface is available in both spherical (crowning) profile and cylindrical profile.
- The stud is either a recessed head type allowing use of a screwdriver or hexagon socket head type so as to be mounted and adjusted easily.

Cam follower Eccentric type —

This is a cam follower (bearing) where the studs of the needle roller type and cylindrical roller type a prescribed are made eccentric. It can then be adjusted by making eccentric the outer ring relative position against the raceway.

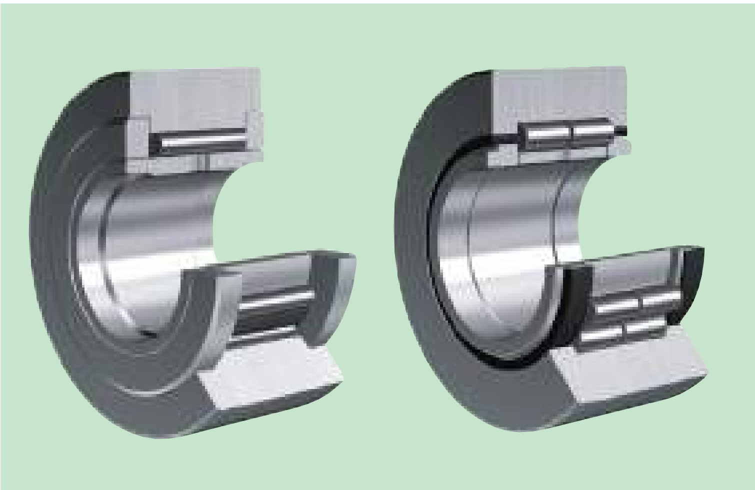
- Load distribution is easily adjustable in configuring two or more cam followers in linear form.
- Preload can be applied by adjustment of load distribution.
- Alignment is possible even when the mounting hole is not processed in high accuracy.
- The outer surface is selectively available in both spherical (crowning) profile and cylindrical profile.
- The stud is either a recessed head type allowing use of a screwdriver or hexagon socket head type so as to be mounted and adjusted easily.

Roller follower —Without axial guide—

This roller follower is a bearing designed for rotation of the outer ring. A needle roller and cage assembly and a synthetic rubber seal reinforced with steel plate are assembled in a thick-walled outer ring.

- The outer ring, the needle roller and cage assembly, and the rubber seal are non-separable from each other.
- The outer ring is thick-walled type so that it is resistible to high load and impact load.
- **A shaft must be provided with a thrust washer and a flange, because the outer ring has no ribs (or face ring) and no axial guide function.**
- The outer surface is available in both spherical (crowning) profile and cylindrical profile.
- The spherical outer ring is effective in damping offset load which is caused by deviation in installing.
- The bearing with cylindrical outer ring is suitable for cases of large load and low-hardness track surface,due to its large area of contact with the mating track surface.

Roller follower —With axial guide—



This roller follower is a bearing designed for rotation of the outer ring. A needle roller and cage assembly, an inner ring, and a face ring are assembled in a thick-walled outer ring.

This bearing uses needle rollers as its rolling element. It is available with a cage or full complement roller bearing without cage. The outer ring is guided axially by a face ring which is press-fitted in the inner ring.

- The outer ring is thick-walled type so that it is resistible to high load and impact load.
- The outer surface is available in both spherical (crowning) profile and cylindrical profile.
- The spherical outer ring is effective in damping offset load which is caused by deviation in installing.
- The bearing with cylindrical outer ring is suitable for cases of large load and low-hardness track surface,due to its large area of contact with the mating track surface.
- This bearing is easier to handle because it needs no mounting of a guide (thrust washer, etc.) on the shaft unlike other types without axial guide (RNA22, NA22).

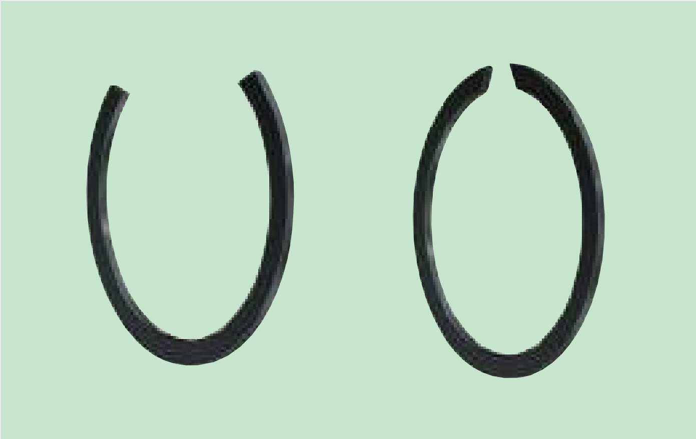
The components described below are for needle roller bearing.

Needle rollers

The needle rollers with flat end round end faces are standard. These rollers are made of high-carbon chrome bearing steel, surface-finished by grinding and buffing after heat-treatment.

- A-Inter-diameter tolerance of the needle rollers is 2mm maximum.
- Rollers with crowned rolling surfaces are also available, which can reduce edge load.
- These needle rollers are supplied individually for applications (pin, shaft).

Snap rings



These are special-purposed rings used for axially positioning, guiding the inner and outer rings, or the needle roller and cage assembly in needle roller bearing.

- Two types are available, for either shaft and/or housing use.
- The snap ring product range cover smaller cross-sectional height products for use in needle roller bearings. The product range also covers snap rings of smaller dimensional range.
- For the axial guide it is recommended to provide a spacer between the cage and the snap ring.

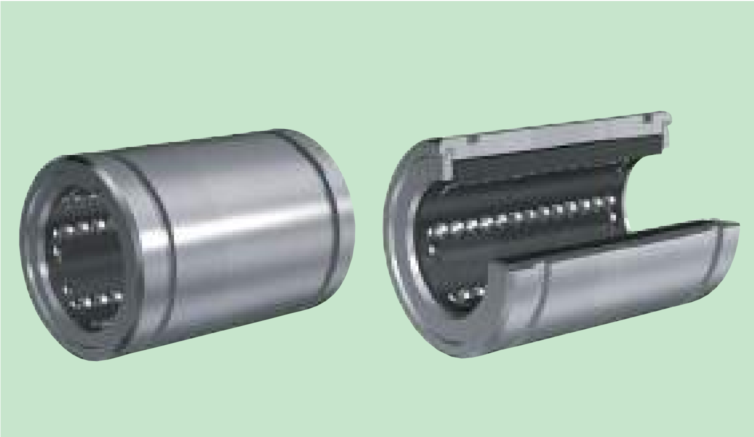
Seals

This product line covers special seals that have been designed for use with low profile needle roller bearings. The product prevents ingress of contamination and help retain grease.

- G-type seal with one lip and GD-type seal with two lips are selectively available on application.
- These seals consist of a ring section formed from steel sheet as well as synthetic rubber material. Their operating temperature ranges from -25 to 120˚C. They are capable of continuous range at a maximum temperature of 100˚C.
- These seals act to prevent the ingress of contamination and over-consumption of lubrication grease.
- The radial section height of each seal is designed to match the drawn-cup needle roller bearings. Hence, these seals require no additional finishing of the housing. This facilitates handling.

This catalogue describes the following ones of linear motion bearings.

Linear ball bearing —Machined ring type—



The product assembly includes a machined outer ring, side plate, steel balls, and a synthetic resin cage that retains the steel balls. This high-precision linear motion bearing develops infinite linear motion on the shaft.

- Standard type, clearance-adjustable type and open type are selectively available on application.
- Some bearings of these types are provided with a synthetic rubber seal at single side or double sides to prevent invasion of foreign matter.
- The steel balls in this product are reliably guided by the cage. Consequently, this product develops stable linear motion on the shaft with minimum frictional resistance.
- **No rotational motion is available.**

Linear ball bearing —Drawn cup type—

The product assembly includes an outer ring formed through precision deep-drawing of thin sheet steel material, steel balls, and a synthetic resin cage that retains the steel balls. This high-precision linear motion bearing develops infinite linear motion on the shaft.

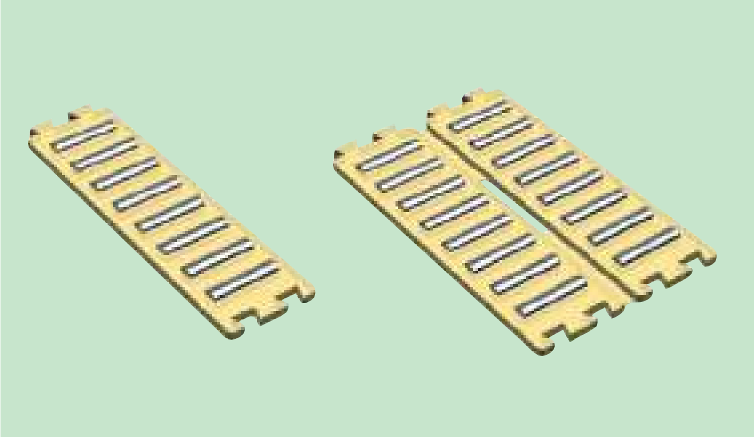
- The outer ring made of thin steel plate creates a smaller section height and allows for a move compact linear motion system.
- Easy to install —This bearing is press-fitted in the housing so that it requires no axial fixing.
- **No rotational motion available.**
- Some bearings of this type are provided with a synthetic rubber seal at double sides to prevent invasion of foreign matter therein.

Linear ball bearing —Stroking type—

The product assembly includes a machined outer ring, side plate, steel balls, and a synthetic resin cage that retains the steel balls. This high-precision bearing rotates and develops finite linear motion on the shaft. The outer ring is provided with a snap ring on both sides and a wavy spring washer is provided between the snap ring and the cage to damp on the impact acting on the cage and to prevent wear of the cage.

- Some bearings of this type are provided with a synthetic rubber seal on each side to prevent invasion of foreign matter.
- The outer ring is grooved so that the snap ring can be fitted and fixed easily.

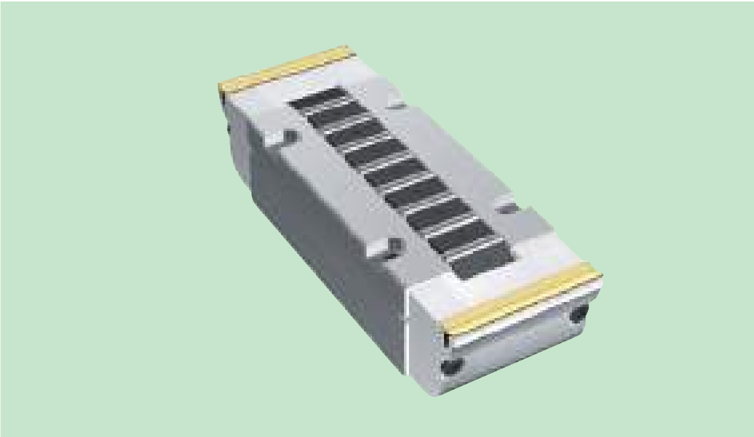
Linear flat roller



This flat roller bearing,comprised of a flat cage and needle rollers, reciprocates on a flat raceway by motion of linear movable components.

- Two material types are available for the cage—synthetic resin and pressed sheet steel.
- FF type molded resin cage – Multiple cages may be joined together in a serial configuration.
- Press-formed steel plate cage – Cage to cage jointing is unavailable, but it can be supplied at any specified length.
- double-row synthetic resin cage has an elastic seam along its center line. When immersed in a hot oil bath heated to 70 to 90˚C the cage can be "folded" to any desired cross-sectional angle so that it can be fitted to a V-sectioned face.

Linear roller bearing

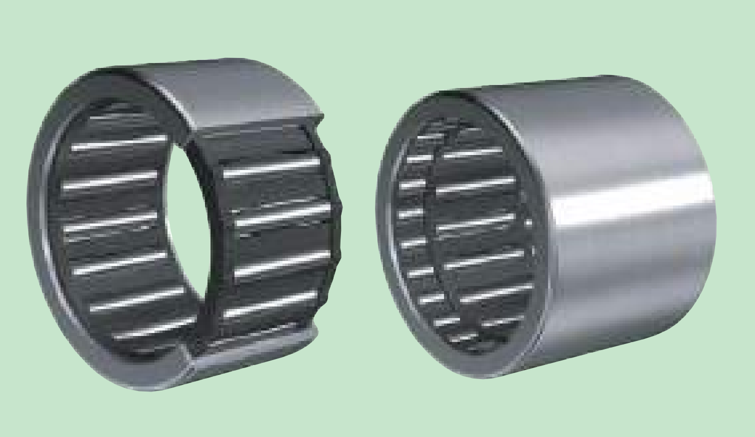


This type has the function of enabling cylindrical rollers to circulate within a track frame and ensures infinite linear motion on a plane.

- Low friction factor due to the cage assembly preventing neighboring rollers from touching each other.
- High load rating due to use of cylindrical rollers

This catalogue describes the following products, too.

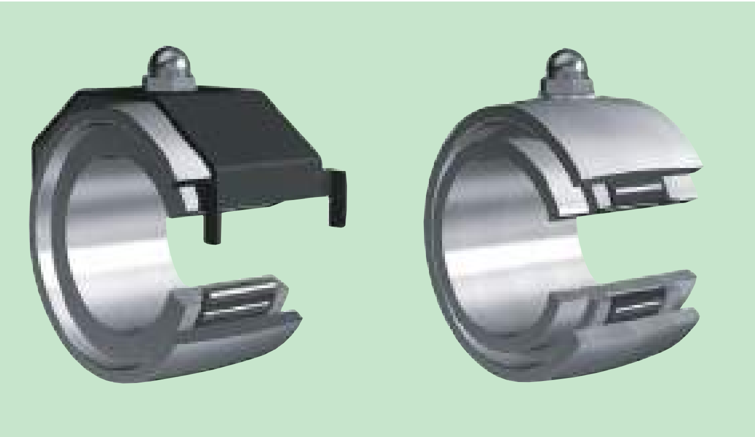
One-way clutch



Comprised of an outer ring drawn from thin special steel plate by precision deep drawing, a spring, needle rollers and a cage, the one-way clutch can transmit torque in only one direction.

- Boasting low frictional torque during over-running, this one-way clutch also features high transmittable torque despite its small cross-sectional height.
- A certain one-way clutch variant has a built-in bearing that supports radial loading. Another variant has a plated outer ring for improved corrosion resistance.
- HF HFL types can be retained axially by merely press-fitting into a housing.
- These one-way clutches use the outer ring drawn by precision deep drawing, which requires a housing with wall thickness of a specified value or more.
- The HF type unit alone is not capable of bearing radial loads, and both ends must be supported with external radial bearings. (On the other hand, HFL type includes integrated radial bearings on each side.)

Bottom roller bearing ~~For~~ textile machinery —



This product has a built-in needle roller bearing pre-filled with grease and is used to support bottom rollers. The spherical outer surface of the outer ring can allow a degree of bottom roller installation error. In order to prevent fiber entry into the bearing, tight clearances are maintained between the outer ring and double-ribbed inner ring, and the rib outer diameter surfaces are knurled.

Tension Pulley ~~For~~ Textile Machinery —

These pulleys are used to guide and tension the tapes and belts driving the spindles of a fine spinning machine, a roving frame, a false twister, etc. The structure is comprised of a precision deep-drawn plate steel pulley which is press-fitted to the outer ring of a bearing.

2. Load Rating and Life

2.1 Bearing life

Even in bearings operating under normal conditions, the surfaces of the raceways and rolling elements are constantly subjected to repeated compressive stresses which causes **flaking** of these surfaces to occur. This flaking is due to material fatigue and will eventually cause the bearing to fail. The effective life of a bearing is usually defined in terms of **the total number of revolutions a bearing can undergo before flaking of either the raceway surface or the rolling element surfaces occur.**

Other causes of bearing failure are often attributed to problems such as seizing, abrasions, cracking, chipping, scuffing, rust, etc. However these so called "causes" of bearing failure are usually themselves caused by improper lubrication, faulty sealing or inaccurate bearing selection. Since the above mentioned "causes" of bearing failure can be avoided by taking the proper precautions, and are not simply caused by material fatigue, they are considered separately from fatigue or flaking.

2.2 Basic rated life and basic dynamic load rating

A group of seemingly identical bearings, when subjected to identical operating conditions will exhibit a wide diversity in their durability. This disparity in lives can be accounted for by differences in the fatigue of the bearing material itself. This disparity is considered statistically when calculating bearing life.

The basic rated life is based on a 90% statistical model. In this model 90% of an identical group of bearings subjected to identical operating conditions will attain or surpass the stated number of revolutions without any flaking due to rolling fatigue. For bearings operating at fixed constant speeds, the basic operating life (90% reliability) is expressed in the total number of hours of operation.

Basic dynamic load rating expressed a rolling bearing's capacity to support a dynamic load. The basic dynamic load rating is the load under which the basic rating life of the bearing is 1 million revolutions. This is expressed as pure radial load for radial bearings and pure axial load for thrust bearings. These are referred to as **basic dynamic radial load rating** (C_r) and **Basic dynamic axial load rating** (C_a).

The basic dynamic load ratings given in the tables of this catalog are for bearings constructed of NTN standard bearing materials using standard manufacturing technologies. For information about the basic dynamic load rating for a bearing using non-standard material and/or manufacturing techniques, contact NTN Engineering.

The relationship between the basic rated life, the basic dynamic load rating and the bearing load can be expressed in formula (2.1).

Basic Rated Life specified in ISO 281.

$$L_{10} = \left(\frac{C}{P}\right)^p \quad \cdots\cdots (2.1)$$

where,

p= 10/3 ··············For roller bearing

p= 3. ··················For ball bearings

L_{10} : Basic rated life (10^6 revolutions)

C : Basic dynamic rated load, (N) (kgf)
(radial bearings: C_r, thrust bearings: C_a)

P : Bearing load, (N) (kgf)
(radial bearings: P_r, thrust bearings: P_a)

Furthermore, the basic rated life can be expressed in hours using **formula (2.2)**

$$L_{10h} = 500 f_h{}^p \quad \cdots\cdots (2.2)$$

$$f_h = f_n \frac{C}{P} \quad \cdots\cdots (2.3)$$

$$f_n = \left(\frac{33.3}{n}\right)^{1/p} \quad \cdots\cdots (2.4)$$

where,

L_{10h} : Basic rated life, h

f_h : Life factor

f_n : Speed factor

n : Rotational speed, r/ min

Formula (2.2) can also be expressed as **formula (2.5).**

$$L_{10h} = \frac{10^6}{60n}\left(\frac{C}{P}\right)^p \quad \cdots\cdots (2.5)$$

When several bearings are incorporated into a piece of equipment it is possible to calculate the bearing life of the whole system by way of **formula (2.6)**

$$L = \frac{1}{\left(\frac{1}{L_1^e} + \frac{1}{L_2^e} + \cdots \frac{1}{L_n^e}\right)^{1/e}} \quad \cdots\cdots (2.6)$$

where,

e = 9/8 ………For roller bearings

e = 10/9 ………For ball bearings

L : Total basic rated life of bearing as a whole, h

L_1 , L_2 ···L_n : Individual basic rated life of bearings, 1, 2,···n, h

2.3 Required bearing life for a give application

When selecting a bearing, it is essential to determine the required life of the bearing under the intended operating conditions. The life requirement is usually determined by the durability and reliability required for the particular application. General guidelines for required life are shown in **Table 2.1**.

While the fatigue life of bearing is an important factor to consider when sizing the bearing it is also important to consider the strengths and rigidities of shaft and housing.

Table 2.1 Operating conditions and required life (reference information)

Operation profile	Life Requirement L_{10h} ×10³ hrs.				
	~4	4~12	12~30	30~60	60~
Machine to be run for a short time or only occasionally.	Home electric appliances Power tools	Agricultural machinery Office equipment			
Machine to be run for a short time or only occasionally; however, the machine needs to perform reliably.	Medical equipment Measuring instruments	Home air-conditioner Construction machinery Elevator Cranes	Cranes (sheave)		
Machine to be run for a prolonged time (but not continuous).	Passenger cars Motor cycles	Compact electric motors Buses and trucks General gearing equipment Woodworking machinery	Spindle on machine tool Multi-purpose electric motor for production plant Crusher Vibration screen	Critical gearing equipment Calender rolls for rubber or plastic materials Offset printing press	
Machine to be always run at least 8 hours a day.		Roll neck on steel rolling machinery Escalator Conveyor Centrifugal separator	Axles on rolling stocks Air-conditioning equipment Large electric motor Compressor and pump	Axles on locomotives Traction motors Hoist for mines Press flywheels	Pulp or paper making machinery Propulsion system for ships
Machine to be run 24 hours a day, and must continue operating even in the event of accident.					City water facility Drain and ventilation system for mines Electric power station equipment

2.4 Adjusted rating life

While the basic rating life (90% reliability) for a given bearing can be calculated with the formulas in Subsection 2.2 a number of factors may be present which adjust that life. In some applications it may be necessary to calculate bearing life at greater than 90% reliability. Special materials or manufacturing processes may be applied to the bearing in an effort to increase life. Furthermore, bearing life may be affected by the operating conditions (lubrication, temperature, running speed, etc.).

The basic rating life can be adjusted to consider these factors. The resultant basic rating life is called the **adjusted rating life**, and can be determined by **formula (2.7)**:

$$L_{na} = a_1 \cdot a_2 \cdot a_3 \ (C/P)^p \quad \cdots\cdots\cdots\cdots \textbf{(2.7)}$$

where,

L_{na} : Adjusted life rating 10^6 revolutions
a_1 : Reliability adjustment factor
a_2 : Bearing material adjustment factor
a_3 : Operating condition adjustment factor

2.4.1 Reliability adjustment factor a_1

The reliability adjustment factor a_1, is used when a reliability higher than 90% is required. Values are shown in **Table 2.2**.

2.4.2 Bearing material adjustment factor a_2 for

When non-standard bearing materials or manufacturing processes are used , the life-related bearing characteristics are inevitably changed. In this case, the bearing life is adjusted using the life adjustment factor, a_2.

The basic dynamic load ratings found in the "Bearing Dimensions Table" of the catalog assume the use of standard **NTN** materials and manufacturing processes / techniques. In this case a_2=1.

When special materials or manufacturing techniques are used in the manufacture of the bearing a_2≠1 will need to be applied. In such a case, feel free to contact **NTN** for further information.

When bearings made of high carbon chrome bearing steel are used at temperatures greater than 120°C for a significant period of time significant dimensional changes will occur in the bearing. To limit these changes and their effect on bearing life a special dimension-stabilizing heat-treatment **(TS treatment)** is used. The specific treatment is determined according to the maximum operating temperature. However, this dimension-stabilizing treatment results in lower bearing hardness which reduces bearing life. To account for this, the bearing life is adjusted using the a_2 factor shown in **Table 2.3**.

Table 2.2 Values of reliability adjustment factor a_1

Reliability %	L_n	Reliability adjustment factor a_1
90	L_{10}	1.00
95	L_5	0.62
96	L_4	0.53
97	L_3	0.44
98	L_2	0.33
99	L_1	0.21

Table 2.3 Life adjustment values (a_2) for dimension-stabilizing heat-treated (TS-treated) bearings

Code	Maximum operating temperature	Life adjustment factor for bearing material a_2
TS2-	160°C	1.00
TS3-	200°C	0.73
TS4-	250°C	0.48

2.4.3 Life adjustment factor for operating conditions a_3

The life adjustment factor for operating conditions (a_3) is used to adjust the bearing life when operating under non-ideal conditions such as deteriorated lubricated, the ingress of foreign matter (contamination) or excessively high the rotational speeds.

Generally the life adjustment factor in the case of optimum lubrication and no contamination a_3=1. When the bearing operates under particularly good conditions it is possible to have a_3>1. However, a_3<1 is applied in the following cases.

- **Low dynamic viscosity of grease or oil at bearing operating temperature**
  Radial needle roller bearing 13mm²/s and less
  Thrust needle roller bearing 20mm²/s and less
- **Particularly low rotational speed**
  (The product of rotational speed n min⁻¹ by pitch circle diameter (D_{pw} mm) of rolling element is $D_{pw} \cdot n$<10000.)
- **High operating temperature of bearing**
  When standard bearings operate at high temperatures hardness of the raceway hardness is reduced, impacting bearing life, In such cases the bearing life is adjusted by multiplying the value shown in **Fig.2.1**. **However, this does not apply to bearings having undergone dimension-stabilizing (TS) treatment**.
- **Ingress of foreign matter (contamination) and/or moisture into lubricant**
  When using a bearing operating under suboptimal conditions please feel free to NTN for assistance in applying the adjustment factors.
  If the lubricating conditions are not favorable a factor of $a_2 \times a_3$<1 is usually applied. This is true even if special materials and manufacturing techniques are used that would result in a life adjustment factor>1.

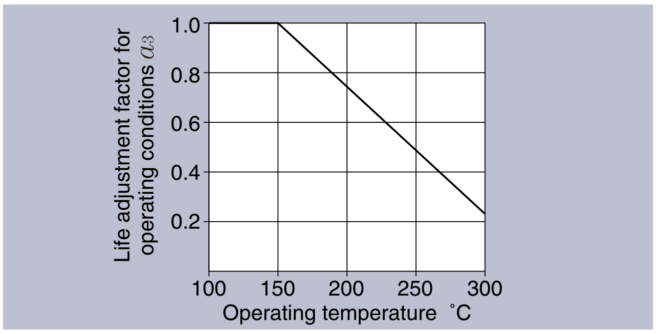


Fig. 2.1 Life adjustment factor for operating conditions depending on operating temperature

2.5 Effect of surface hardness on basic dynamic load rating

It is possible to use the shaft or housing surface as the raceway surface. Under these conditions the surface layer of the shaft/housing must be hardened to HRC58 to 64 and a proper hardening depth must be achieved.

Methods such as ordinary quenching, carburizing or induction quenching can be used to harden the shaft/housing. If it is not possible to sufficiently harden the surface the load rating of the bearing will need to be reduced. The basic load rating must be adjusted by multiplying the hardness factor shown in **Fig.2.2**.

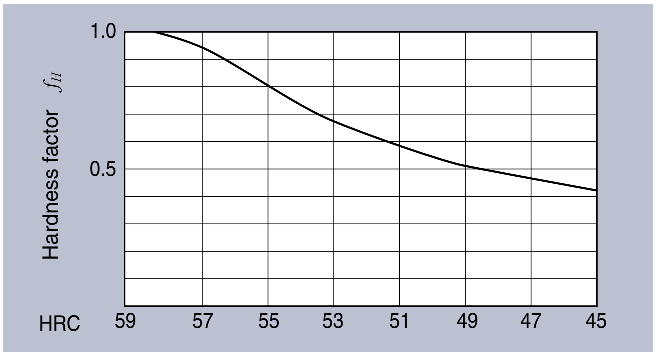

Fig. 2.2 Hardness factor

2.6 Bearing life under oscillating motion

The life of a bearing under oscillating motion can be determined by **formula (2.8)**.

$$L_{osc} = \Omega L_{Rot} \quad \text{(2.8)}$$

where,

L_{osc} : Life of bearing with oscillating motion
L_{Rot} : Life of bearing subject to rotational speed min⁻¹ identical to oscillation frequency cpm
Ex.) Rating life determined from 90 min⁻¹ that is equivalent to cyclic rate of 90 cpm.
Ω : Oscillation factor (showing the relation with half angle β of oscillation angle per **Fig.2.3**).

Generally, **Fig.2.3** applies to cases where the critical oscillation angle 2β is greater than the critical oscillation angle $2\beta_C$. Critical oscillation angle is principally governed by the internal design of the bearing; in particular, the number of rolling elements included in one row.

There may be a case where the bearing needs to be used at an angle smaller than its critical oscillation angle: however, the bearing life will be shorter than the

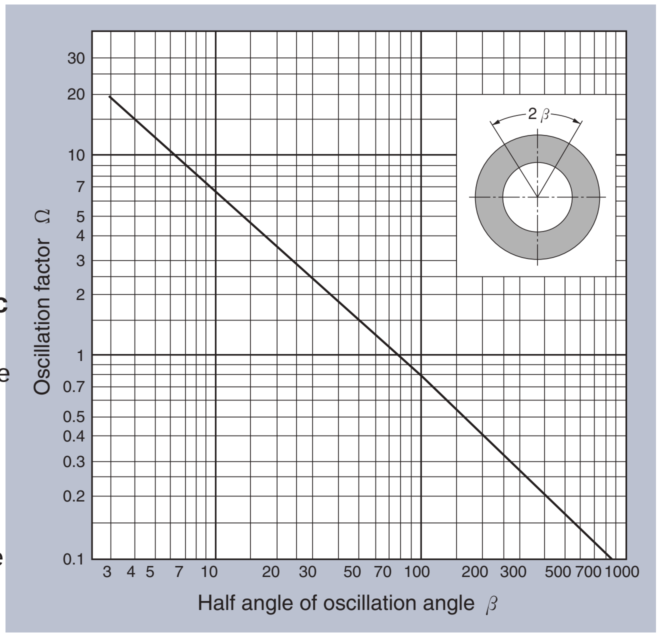

Fig. 2.3 Relationship of oscillation angle β and factor Ω

calculated life determined using the data in **Fig.2.3**. If the oscillation angle of the bearing is unknown, determine Ω, assuming that $\beta = \beta_2$. For the data about an intended bearing, contact **NTN** Engineering.

When the oscillation angle 2β is very small, difficulty in forming an oil film on the contact surface of rolling ring to rolling element could result in **fretting** corrosion.

In the case of inner ring oscillation, the critical oscillation angle is expressed in **formula (2.9)**.

$$\text{Critical oscillation angle } 2\beta_c \geqq \frac{360°}{Z} \cdot \frac{D_{pw}}{D_{pw} - D_w \cos\alpha} \quad \cdots\textbf{(2.9)}$$

Where,

Z : Number of rolling elements (per row)
d_p: Pitch circle diameter (PCD) of rolling element
D_p: Rolling element diameter
e : Contact angle

(In the case of outer ring oscillation, the right side denominator is $D_{pw} + D_w \cos\alpha$.)

2.7 Life of bearing with linear motion

In the case of bearings with linear motion such as linear ball bearing, linear flat roller bearing, etc., the relationship among axial travel distance, bearing load and load rating can be expressed in **formulas (2.10)**, **(2.11)**.

When the rolling elements are balls;

$$L = 50 \times \left(\frac{C_r}{P_r}\right)^3 \quad \cdots\cdots\textbf{(2.10)}$$

When the rolling elements are rollers;

$$L = 100 \times \left(\frac{C_r}{P_r}\right)^{10/3} \quad \cdots\cdots\textbf{(2.11)}$$

where,

L : Load rating km
C_r : Basic dynamic load rating N (kgf)
P_r : Bearing load N (kgf)

Fig.2.4 shows the relationship of C_r/P_r to L.

Furthermore, when the travel motion frequency and travel distance remain unchanged, the lifetime of bearing can be determined by **formulas (2.12)**, **(2.13)**.

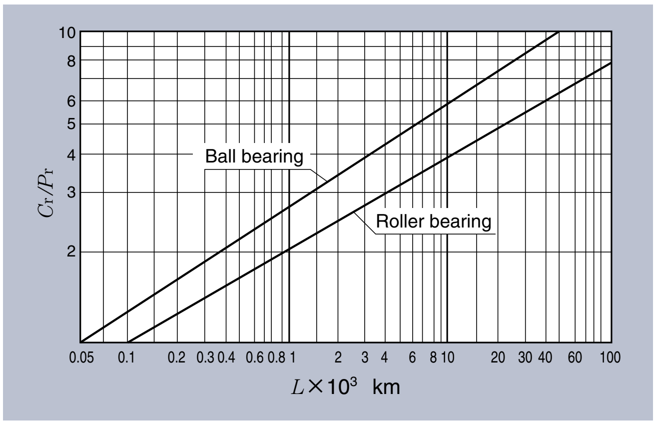

Fig. 2.4 Life of bearing with axial motion

When the rolling elements are balls;

$$L_h = \frac{50 \times 10^3}{60 \cdot S}\left(\frac{C_r}{P_r}\right)^3 \quad \cdots\cdots\textbf{(2.12)}$$

When the rolling elements are rollers;

$$L_h = \frac{100 \times 10^3}{60 \cdot S}\left(\frac{C_r}{P_r}\right)^{10/3} \quad \cdots\cdots\textbf{(2.13)}$$

where,

L_h: Travel life h
S : Travel distance per minute m/min
$S = 2 \cdot L \cdot n$
L : Stroke length m
n : Stroke cycle cpm

2.8 Fitting misalignment and crowning

Generally it is well known that stress concentrations at the edge portion of the roller (so called, edge load) arising from fitting misalignment could result in rapid reduction of bearing lifetime. "Crowning" is adopted as a countermeasure against such rapid reduction of bearing lifetime. In that case, however, unless it is designed properly this crowning would cause the effective contact length of the roller to be reduced, which could then lead to shorter bearing life. It is therefore necessary to calculate a proper crowning based on the extent of fitting misalignment and load condition.

For Reference purposes, **Figs. 2.5** to **2.7** show computer generated examples of contact surface pressure profiles for various scenarios. These profiles demonstrate how crowning can reduce edge surface contact pressure in conditions of misalignment.

Fig. 2.8 shows an example of a computer generated relationship between allowable fitting misalignment and bearing life. It is possible to see from this Figure how the bearing lifetime is influenced by fitting misalignment.

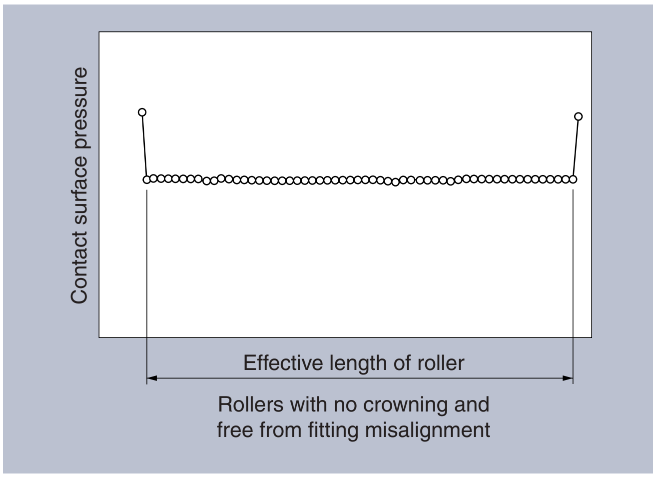

Fig. 2.5

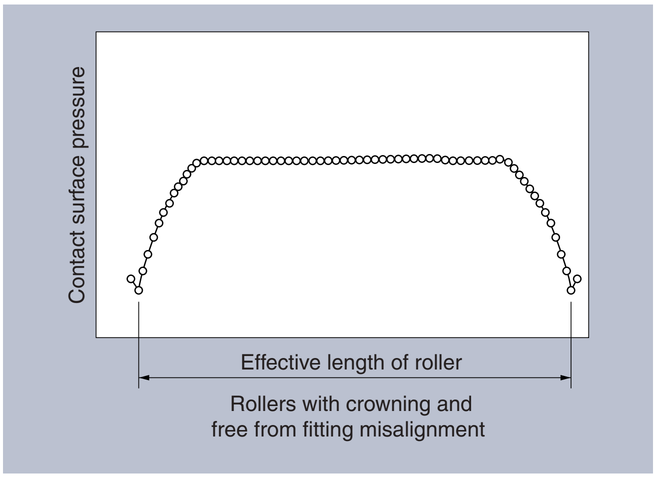

Fig. 2.7

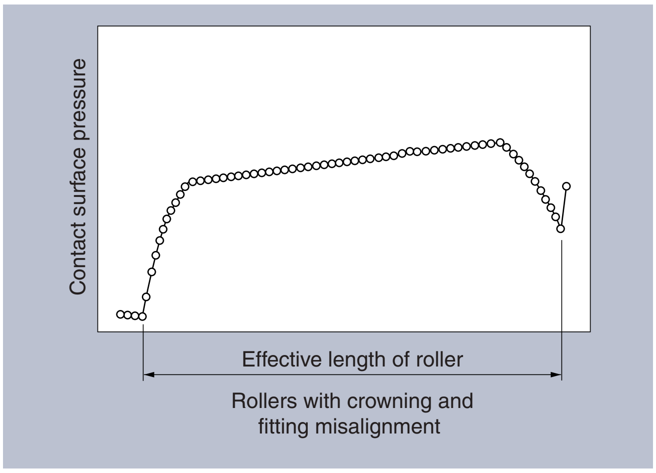

Fig. 2.6

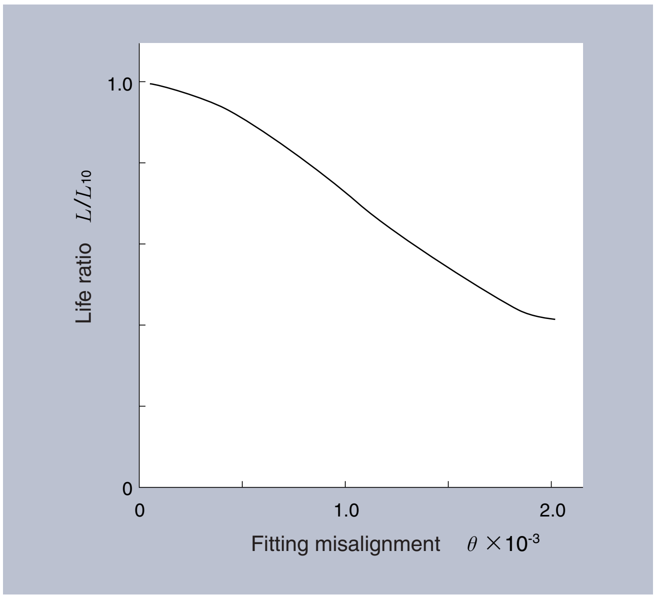

Fig. 2.8 Relationship of fitting misalignment to bearing lifetime

2.9 Basic static load rating

"Basic static load rating" is defined as the minimum static load acting on the center of a rolling element which results in a calculated contact stress value of:

4,000 MPa (408kgf/mm^2) for Roller bearings.

4,200 MPa (428kgf/mm^2) for Ball Bearings.

It has been empirically shown that the resulting permanent deformation on the rolling element and raceway caused by these magnitudes of contact stress is approximately 0.0001 time as great as the diameter of rolling element, and that this deformation level is maximum allowable deformation for smooth running of the bearing.

Basic static load rating for radial bearings is known as **"basic static radial load rating"**, and that for axial thrust bearing as **"basic static axial load rating"**. The bearing dimension tables in this catalog provide data for these load rating types under the parameter names C_{0r} and C_{0a}.

2.10 Allowable static bearing load

The basic static load rating described in **Subsection 2.9** is generally deemed as an allowable static bearing limit load, but in some cases this allowable limit load is set up larger than the basic static load rating and in some other cases it is set up smaller, according to the requirements for revolving smoothness and friction.

Generally this allowable limit load is decided considering the safety factor So in the following **formula (2.14)** and **Table 2.4**.

$$S_0 = C_0 / P_0 \cdots\cdots \textbf{(2.14)}$$

where,

S_0 : Safety factor

C_0 : Basic static rated load, N (kgf)
(For radial bearings: C_{0r},
For thrust bearings: C_{0a})

$P_{0\,max}$: Maximum static bearing load, N (kgf)
(For radial bearings: P_{0r}max,
For thrust bearings: P_{0a}max)

Table 2.4 Lower limit value of safety factor S_0

Operating conditions	Roller bearings	Ball bearings
Requirement for high revolving accuracy	3	2
Requirement for ordinal revolving accuracy (ordinary-purposed)	1.5	1
Where minor deterioration of revolving accuracy is allowed (Ex. Low speed revolution, duty load application, etc.)	1	0.5

Remarks: 1. The lower limit of S_0 for drawn cup needle roller bearings is set at 3; for Premium Shell Product, the limit is set at 2.
2. The lower limit of S_0 is set at 3 for an application where the AS type raceway is used in an axial thrust bearing.
3. Where vibration and shock load act on bearing, P_0 max shall be determined considering the shock load factor.

3. Calculation of Bearing Loads

To compute bearing roads, the forces which act on the shaft being supported by the bearing must be determined. These forces include the inherent dead weight of the rotating body (the weight of the shafts and components themselves), loads generated by the working forces of the machine, and loads arising from transmitted power.

It is possible to calculate theoretical values for these loads; however, there are many instances where the load acting on the bearing is usually determined by the nature of the load acting on the main power transmission shaft.

3.1 Load acting on shafts

3.1.1 Load factors

The actual shaft loads on a machine that uses a bearing are usually greater than the theoretically determined values owing to vibration and impact occurring on the machine. For this reason, loads actually acting on a shaft system are often determined through multiplication by an appropriate load factors listed in **Table 3.1** and **Table 3.2**.

$$K = f_w \cdot f_z \cdot K_c \quad \cdots\cdots \textbf{(3.1)}$$

where

K : Actual load acting on shaft N (kgf)
K_c : Theoretically calculated value N (kgf)
f_w : Load factor **(Table 3.1)**
f_z : Gear factor **(Table 3.2)**

Table 3.1 Load factor f_w

Extent of shock	f_w	Application
Nearly no shock	1.0–1.2	Electrical machines, machine tools, measuring instruments
Light shock	1.2–1.5	Railway vehicles, automobiles, rolling mills, metal working machines, paper making machines, rubber mixing machines, printing machines, aircraft, textile machines, electrical units, office equipment
Heavy shock	1.5–3.0	Crushers, agricultural machines, construction machines, cranes

Table 3.2 Gear factor f_z

Types of gear	f_z
Precision ground gears (Pitch and profile errors of less than 0.02mm)	1.05–1.1
Ordinary machined gears (Pitch and profile errors of less than 0.1mm)	1.1–1.3

3.1.2 Load acting on gears

The loads acting on gears can be divided into tangential load (K_t), radial load (K_s), and axial load (K_a). The magnitude and acting direction of each load differ depending on the types of gear. This paragraph describes how to calculate the loads acting on parallel shaft gears and cross shaft gears for general use.

(1) Load acting on parallel shaft gear

Figs. 3.1 to **3.3** illustrate the loads acting on spur gear and helical gear which are used with a parallel shaft. The magnitude of each load can be determined using the **formulas (3.2)** to **(3.5)**.

$$\left.\begin{aligned} K_t &= \frac{19.1\times10^6 \cdot H}{D_p \cdot n} \quad \text{N} \\ K_t &= \frac{1.95\times10^6 \cdot H}{D_p \cdot n} \quad \text{(kgf)} \end{aligned}\right\} \quad \cdots\cdots \textbf{(3.2)}$$

$$K_s = K_t \cdot \tan\alpha \ \text{(Spur gear)} \quad \cdots\cdots \textbf{(3.3a)}$$

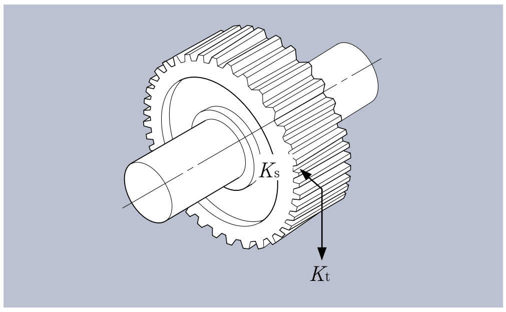

Fig. 3.1 Load acting on spur gear

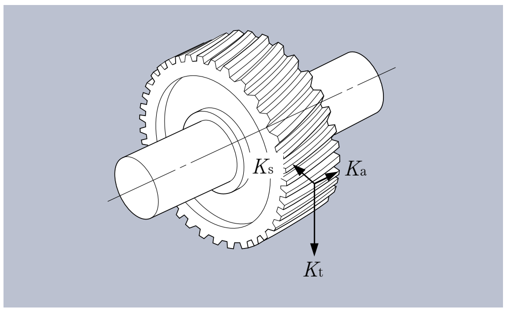

Fig. 3.2 Load acting on helical gear

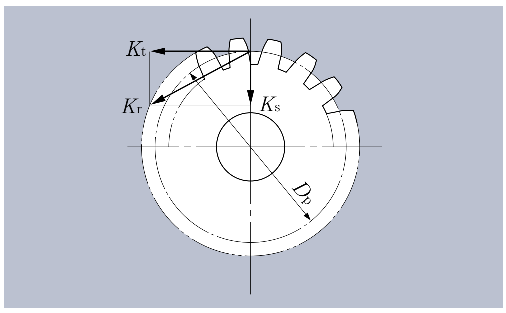

Fig. 3.3 Composite radial force acting on gear

$$=K_t \cdot \frac{\tan\alpha}{\cos\beta} \text{ (for helical gear)} \cdots\cdots \textbf{(3.3b)}$$

$$K_r = \sqrt{K_t^2 + K_s^2} \cdots\cdots \textbf{(3.4a)}$$

$$K_a = K_t \cdot \tan\beta \text{ (for helical gear)} \cdots\cdots \textbf{(3.5)}$$

where,

K_t : Tangential load acting on gear (Tangential force) N (kgf)
K_s : Radial load acting on gear (separating force) N (kgf)
K_r : Load acting perpendicularly on gear shaft (composite force of tangential force and separating force) N (kgf)
K_a : Parallel load acting on gear shaft N (kgf)
H : Transmission power kw
n : Rotational speed min^{-1}
D_p : Pitch circle diameter of gear mm
α : Gear pressure angle deg
β : Gear helix angle deg

(2) Loads acting on cross shaft gears

Figs. 3.4 and **3.5** illustrate the loads acting on straight-tooth bevel gears and spiral bevel gears which are used with cross shafts.

The calculation methods for these gear loads are shown in **Table 3.3**. Herein, to calculate gear loads for straight bevel gears, the helix angle (β) is 0.

K_t : Tangential load acting on gear (Tangential force) N (kgf)
K_s : Radial load acting on gear (separating force) N (kgf)
K_a : Parallel load acting on gear shaft (axial load) N (kgf)
H : Transmission power kw
n : Rotational speed min^{-1}
D_{pm} : Mean pitch circle diameter mm
α : Gear pressure angle deg
β : Gear helix angle deg
δ : Pitch cone angle of gear deg

In general, the relationship between the loads acting on pinion and pinion gear can be expressed as follows, due to the perpendicular intersection of two shafts.

$$K_{sp} = K_{ag} \cdots\cdots \textbf{(3.6)}$$

$$K_{ap} = K_{sg} \cdots\cdots \textbf{(3.7)}$$

where,

K_{sp}, K_{sg} : Pinion and pinion gear separating force N (kgf)
K_{ap}, K_{ag} : Axial load acting on pinion and pinion gear N (kgf)

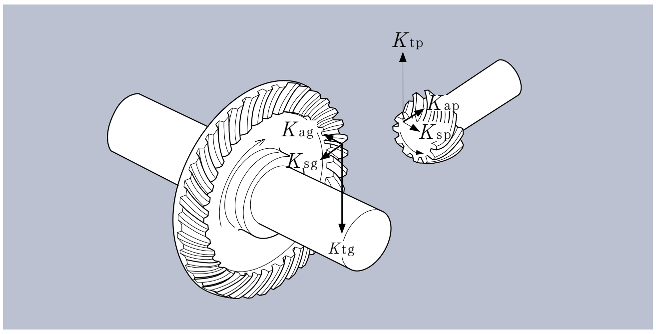

Fig. 3.4 Load acting on bevel gears

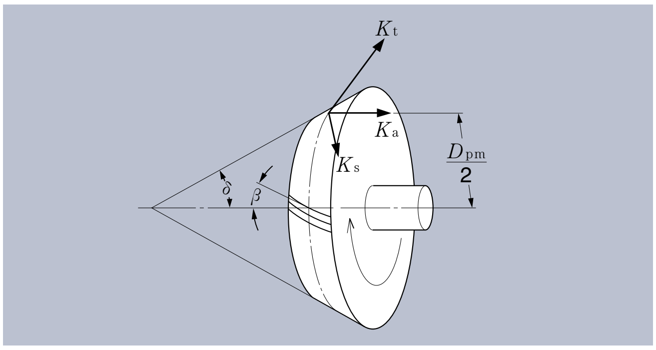

Fig.3.5 Bevel gear diagram

Table 3.3 Calculation formulas for determining loads acting on bevel gears

Unit N

Type of load	Rotational direction	Clockwise	Counter clockwise	Clockwise	Counter clockwise
	Helix angle	To right	To left	To left	To right
Tangential load (tangential force) K_t		$K_t = \frac{19.1\times10^6 \cdot H}{D_{pm}\cdot n}$, $\left\{\frac{1.95\times10^6 \cdot H}{D_{pm}\cdot n}\right\}$			
Radial load (separating force) K_s	Drive side	$K_s = K_t\left[\tan\alpha\frac{\cos\delta}{\cos\beta} + \tan\beta\sin\delta\right]$		$K_s = K_t\left[\tan\alpha\frac{\cos\delta}{\cos\beta} - \tan\beta\sin\delta\right]$	
	Driven side	$K_s = K_t\left[\tan\alpha\frac{\cos\delta}{\cos\beta} - \tan\beta\sin\delta\right]$		$K_s = K_t\left[\tan\alpha\frac{\cos\delta}{\cos\beta} + \tan\beta\sin\delta\right]$	
Load parallel to gear train (Axial load) K_a	Drive side	$K_a = K_t\left[\tan\alpha\frac{\sin\delta}{\cos\beta} - \tan\beta\cos\delta\right]$		$K_a = K_t\left[\tan\alpha\frac{\sin\delta}{\cos\beta} + \tan\beta\cos\delta\right]$	
	Driven side	$K_a = K_t\left[\tan\alpha\frac{\sin\delta}{\cos\beta} + \tan\beta\cos\delta\right]$		$K_a = K_t\left[\tan\alpha\frac{\sin\delta}{\cos\beta} - \tan\beta\cos\delta\right]$	

The orientation of loading on a spiral bevel gear will vary depending on the direction of the helix angle, the direction of rotation and whether the gear is a driving or driven gear.

The separating force (K_r) and the axial load (K_a) are shown in the positive direction in **Fig. 3.5**. The direction of rotation and the helix direction are defined as viewed from the large end of the gear. For the gear illustrated in **Fig. 3.5** these directions are clockwise and to the right.

3.1.3 Loads acting on chain and belt shafts

When power is transmitted by means of a chain or belt as illustrated in **Fig. 3.6**, the loads acting on the sprocket or pulley can be determined by **formula (3.8).**

$$K_t = \frac{19.1\times10^6 \cdot H}{D_p \cdot n} \left(\frac{1.95\times10^6 \cdot H}{D_p \cdot n}\right) \quad \cdots\cdots\cdots(3.8)$$

where,

K_t : Load acting on sprocket or pulley N (kgf)

HP : Transmission power kW

D_p : Pitch circle diameter of sprocket or pulley mm

For belt drives, an initial tension is applied to ensure sufficient normal force between the belt and pulley during operation.

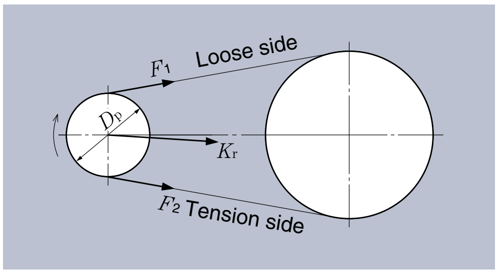

Fig. 3.6 Loads acting on chain/ belt

Taking into account the initial tension, the radial load acting on the pulley can be determined by **formula (3.9)**. For chain drives, the radial load can be expressed using the same formula, if vibration and shock are taken into consideration.

$$K_r = f_b \cdot K_t \quad \cdots\cdots\cdots(3.9)$$

where,

K_r : Radial load acting on sprocket or pulley N (kgf)

f_b : Chain/belt factor **(Table 3.4)**

Table 3.4 Chain/belt factor f_b

Type of chain / belt	f_b
Chain (single row type)	1.2–1.5
Vee-belt	1.5–2.0
Timing belt	1.1–1.3
Flat belt (with tension pulley)	2.5–3.0
Flat belt	3.0–4.0

3.2 Bearing load distribution

Any loads acting on shafts are distributed to the bearings. The bearing load distribution is determined by considering the shaft to be a static beam supported by the bearings.

For example, the loads acting on the bearings supporting the gear shaft illustrated in **Fig. 3.7** can be expressed using **formulas (3.10)** and **(3.11)**.

$$F_{rA} = K_{rI}\frac{b}{l} - K_{rII}\frac{c}{l} - K_a\frac{D_p}{2l} \quad \cdots\cdots\cdots(3.10)$$

$$F_{rB} = K_{rI}\frac{a}{l} + K_{rII}\frac{a+b+c}{l} + K_a\frac{D_p}{2l} \quad \cdots\cdots\cdots(3.11)$$

where,

F_{rA} : Radial load acting on bearing-A N (kgf)

F_{rB} : Radial load acting on bearing-B N (kgf)

K_{rI} : Radial load acting on gear-I N (kgf)

K_a : Axial load acting on gear-I N (kgf)

K_{rII} : Axial load acting on gear-II N (kgf)

D_p : Pitch circle diameter of gear-I mm

l : Bearing to bearing distance mm

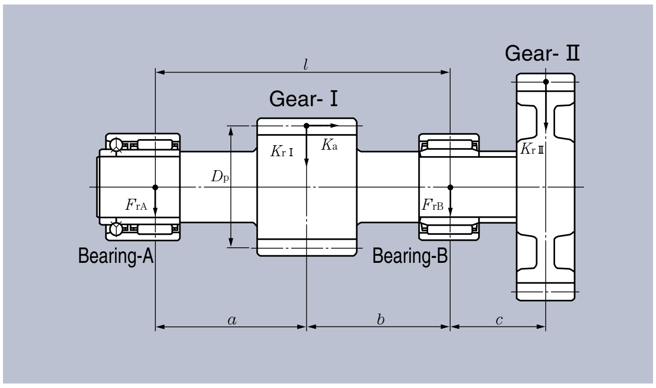

Fig. 3.7 Gear shaft

3.3 Mean load

The load on bearings used in machines will often fluctuate according to a fixed duty cycle. The load on bearings operating under such conditions can be converted to a mean load (F_m). The mean load is a load which gives the bearings the same life they would have under constant operating conditions.

(1) Stepped fluctuating load

The mean bearing load, F_m, for stepped loads is calculated using **formula (3.12)**. where F_1, F_2 .... F_n are the bearing loads, and the rotational speed and running time are n_1, n_2.......n_n and t_1, t_2....... t_n respectively.

$$F_m=\left(\frac{\Sigma\,(F_i^{\,p}\,n_i\,t_i)}{\Sigma\,(n_i\,t_i)}\right)^{1/p} \cdots\cdots(3.12)$$

where:
p=10/3 for roller bearing
p=3 for ball bearing

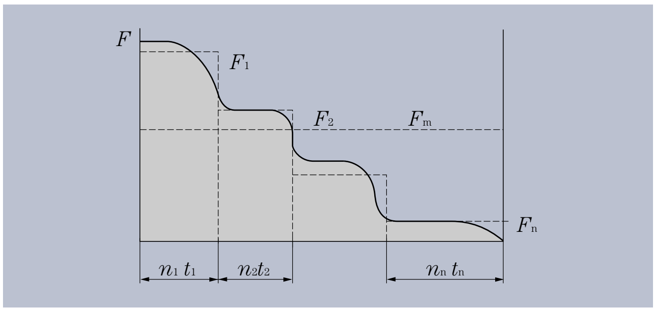

Fig. 3.8 Stepped fluctuating load

(2) Cyclical load

Where the bearing load can be expressed as a function of time $F(t)$, repeating with cycle time t_0, the mean load can be expressed **formula (3.13)**.

$$F_m=\left(\frac{1}{t_0}\int_0^{t_0} F\,(t)^p\,dt\right)^{1/p} \cdots\cdots(3.13)$$

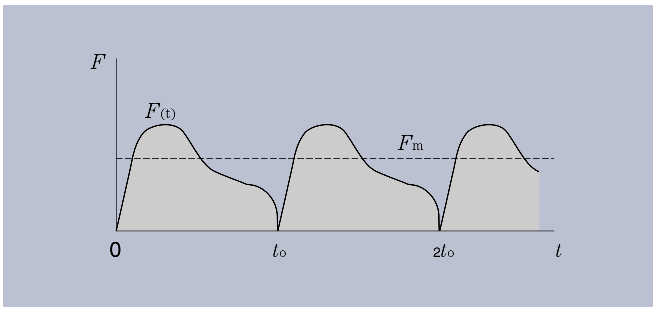

Fig. 3.9 Load fluctuating as cyclical function of time

(3) Linearly fluctuating load

The mean load F_m can be approximated by **formula (3.14)**.

$$F_m=\frac{F_{min}+2F_{max}}{3} \cdots\cdots(3.14)$$

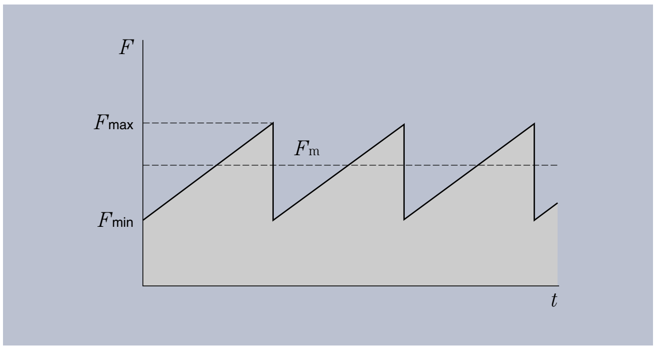

Fig. 3.10 Linearly fluctuating load

(4) Sinusoidal load

The mean load F_m can be approximated by **formulas (3.15)**, and **(3.16)**.

case of (a) $F_m=0.75F_{max}$ ··········**(3.15)**
case of (b) $F_m=0.65F_{max}$ ··········**(3.16)**

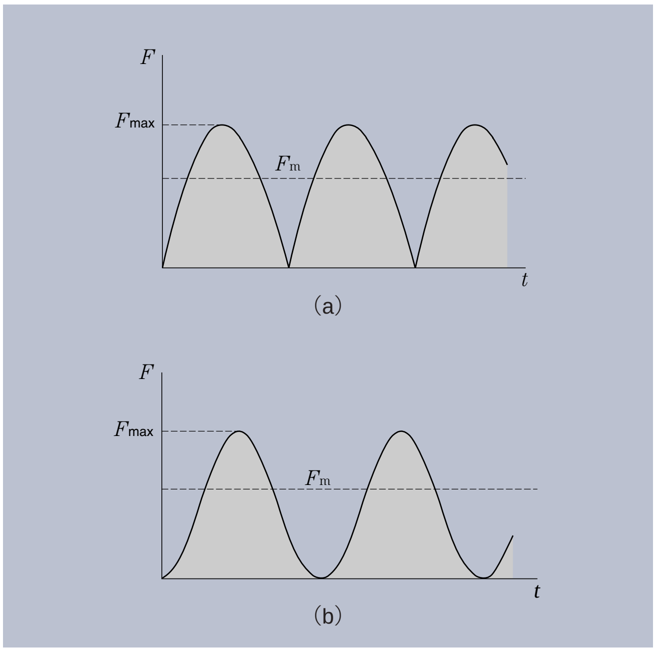

Fig. 3.11 Sinusoidal load

4. Bearing Accuracy

The dimensional, profile and running accuracies of rolling bearings are specified in ISO Standard as applicable and JIS B 1514 (Accuracy of Rolling Bearings).

"**Dimensional accuracy**" and "**Profile accuracy**" are the items indispensable in installing the rolling bearings on a shaft and in a bearing housing, and allowable bearing run-out in running is specified as the running accuracy.

Dimensional accuracy:

Dimensional accuracy means the respective allowable values for bore diameter, outer diameter, width or height (limited to thrust bearing) and chamfering dimension.

Profile accuracy:

Profile accuracy relates to tolerances for inside diameter variation, mean inside diameter variation, outside diameter variation, mean outside diameter variation, and ring width variation.

Running accuracy:

Running accuracy relates to tolerances for radial runout and axial runout with inner ring and outer ring, perpendicularity of ring face, perpendicularity of outside surface, and raceway thickness variation (thrust bearing).

Regarding the accuracy class of the machined ring needle roller bearings, class-0 is equivalent to bearings of the normal precision class, and precision becomes progressively higher as the class number becomes smaller; i.e. Class 6 is less precise than Class 5, which is less precise than Class 4, and so on.

Bearings of Class-0 are mostly used for general applications while bearings of Class-5 or Class-4 are used where the required running accuracies and revolutions are high or less friction and less fluctuation are required for bearings.

Various bearing types are available for NTN needle roller bearings and the representative types and the accuracy classes applicable to them are as shown in **Table 4.1**.

Dimensional item symbols used in the accuracy standard are given in **Table 4.2**, the radial bearing accuracy specified every accuracy class given in **Table 4.3**, the thrust bearing accuracy specified every accuracy class given in **Table 4.4**, and the allowable values for chamfering dimension given in **Table 4.5**.

5. Bearing Internal Clearance

5.1 Bearing internal clearance

Bearing radial internal clearance (free clearance) is the amount of internal clearance a bearing has before being installed on a shaft or into a housing. When either the inner ring or the outer ring is fixed and the other ring is free to move, displacement takes place in the radial direction. This amount of displacement is called the radial internal clearance.

The radial internal clearance values of NTN machined ring needle roller bearings are listed in **Table 5.1**. **Table 5.1 (1)** shows the interchangeable clearances, which remain unchanged even if inner or outer ring are switched with those from different bearings. **Table 5.1 (2)** shows non-interchangeable clearances, which are supplied as matched sets due to the tighter clearance ranges. Bearing clearances are represented by the symbols C2, normal, C3, and C4 in increasing order from smallest to largest. Non-interchangeable clearances symbols are followed by "NA" for identification.

For radial clearance values for bearings other than machined ring needle roller bearings, refer to "Commentary" provided with the appropriate dimension tables.

5.2 Running clearance

5.2.1 Running clearance selection

The internal clearance of a bearing under operating conditions (**running clearance**) is usually smaller than the same bearing's free clearance. This is due to several factors including bearing fit, the difference in temperature between the inner and outer rings, etc. As a bearing's operating clearance has an effect on bearing life, heat generation, vibration, noise, etc.; care must be taken in selecting the most suitable operating clearance.

Theoretically, regarding bearing life, the optimum operating internal clearance of any bearing would be a slight negative clearance after the bearing has reached normal operating temperature.

Unfortunately, under actual operating conditions, maintaining such optimum tolerances is often difficult at best. Due to various fluctuating operating conditions this slight minus clearance can quickly become a large minus, greatly lowering the life of the bearing and causing excessive heat to be generated. Therefore, an initial internal clearance that will result in a slightly greater than minus internal operating clearance should be selected.

Under normal operating conditions (e.g. normal load, fit, speed, temperature, etc.), a standard internal clearance will give a very satisfactory operating clearance.

5.2.2 Calculation of running clearance

The internal clearance differential between the free clearance and the operating (running) clearance (the amount of clearance reduction caused by interference fits, or clearance variation due to the temperature difference between the inner and outer rings) can be calculated by the following formula:

$$\delta_{eff} = \delta_o - (\delta_f + \delta_t) \quad \cdots\cdots\cdots\cdots\cdots\cdots\cdots\textbf{(5.1)}$$

where,

δ_{eff} : Running clearance mm

δ_o : Free clearance mm

δ_f : Reduction in internal clearance by interference mm

δ_t : Reduction in internal clearance due to inner/outer ring temperature difference mm

(1) Reduction in radial clearance by interference

When bearings are installed with interference fits on shafts and in housings, the inner ring will expand and the outer ring will contract; thus reducing the bearing' s internal clearance. The amount of expansion or contraction varies depending on the shape of the bearing, the shape of the shaft or housing, dimensions of the respective parts, and the type of materials used. The differential is approximately 85% of the effective interference. For details, refer to **Table 6.4** on page A-35.

$$\delta_f \approx 0.85 \cdot \Delta d_{eff} \quad \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\textbf{(5.2)}$$

where,

δ_f : Reduction in internal clearance by interference mm

Δd_{eff} : Effective interference mm

(2) Reduction in radial clearance due to inner/outer ring temperature difference

During operation, normally the outer ring will be from 5 to l0°C cooler than the inner ring or rolling elements. However, if the cooling effect of the housing is large, the shaft is connected to a heat source, or a heat substance is conducted through a hollow shaft; the temperature difference between the two rings can be even greater. The amount of internal clearance is thus further reduced by the differential expansion of the two rings.

$$\delta_t = \alpha \cdot \Delta_T \cdot D_o \quad \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\textbf{(5.3)}$$

where,

δ_t : Reduction in internal clearance due to inner/outer ringtemperature difference mm

α : Linear expansion coefficient of bearing steel 12.5×10^{-6}/°C

Δ_T : Inner ring – outer ring temperature difference ℃

D_o : Outer ring raceway diameter mm

When a shaft or housing is directly used as a raceway, the temperature difference(Δ_t) can be determined, treating the shaft as an inner ring and the housing as an outer ring.

5.3 Fits and bearing radial internal clearance

Once the dimensional tolerances for the shaft outside diameter and the housing bore diameter have been determined, a simple nomogram such as a one in **Fig. 5.1** may be used as a guide to determine the initial radial internal clearance for the bearing that will later lead to an appropriate internal clearance of the installed bearing. The nomogram in **Fig. 5.1** is used as the guideline as stated above. For details feel free to contact **NTN**.

For example, where the fit condition of a needle roller bearing with an inner ring is already given as J7 m6, **Fig.5.1** shows that clearance C3 must be used to get the standard running clearance after installation.

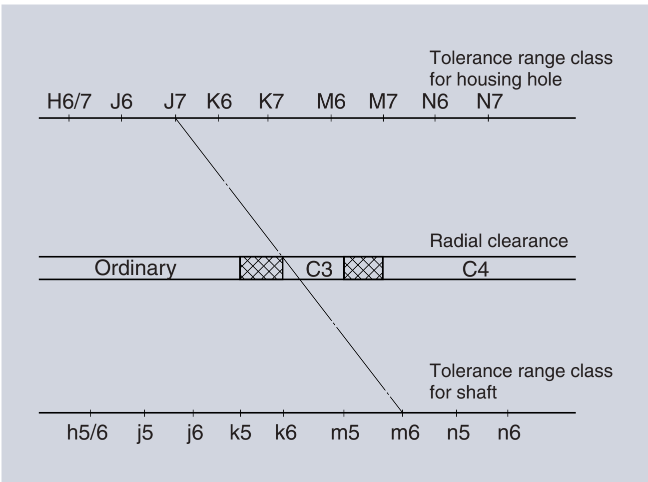

Fig. 5.1 Relationship between bearing fits and radial clearance

6. Bearing Fits

6.1 About bearing fits

For rolling bearings, the inner ring and outer ring are fixed on the shaft or in the housing so that relative movement does not occur between the fitted surfaces of the bearing ring and the shaft or housing in radial, axial and rotational directions when a load acts on the bearing. Depending on presence/absence of interference, fit modes can be categorized into **"interference fit"**, **"transition fit"**, and **"loose fit"**.

The most effective practice to position a bearing is to provide an interference on the fit surfaces between the bearing ring and shaft or housing. Furthermore, as its advantage this tight fit method supports the thin-walled bearing ring with uniform load throughout its entire circumference without any loss of load carrying capacity.

The needle roller bearing is a bearing type which allows separation of the inner ring and the outer ring from one another and, therefore, it can be installed on a shaft or in a housing with an interference applied to both. In the case of "tight fit", the ease of bearing installation and removal. The bearing ring subjected to stationary load can be "loose-fitted". In contrast, tight fitting may not apply to all bearing applications because ease of mounting or removal of the bearing will be jeopardized.

6.2 Necessity of proper fit

Improper fit could lead to damage and shorter life of the bearing. Therefore, advance careful analysis is needed for selection of proper fit. Representative examples of bearing defects caused by improper fit are as described below.

- Fracture of bearing ring, and displacement of bearing ring
- Wear of bearing ring, shaft and housing caused by creep and fretting corrosion
- Seizure caused by insufficient internal clearance
- Insufficient running accuracy and abnormal noise caused by deformed raceway surface

6.3 Fit selection

Fit selection is generally done in accordance with the rule specified hereunder.

The loads acting on each bearing ring are divided into running load, stationary load and directionally unstable load according to the direction and characteristic of loads acting on the bearing.

A bearing ring that carries both running load and indeterminate direction load is provided with tight fit while a bearing ring that carries static load may be provided with either transition fit or loose fit (refer to **Table 6.1**).

Where load of high magnitude or vibration and shock loads act on a bearing or if a light alloy/plastic housing is used, it is necessary to secure a large interference. **However, if this type of practice is applied, it is necessary to consider the rigidity of housing in order avoid problems including deformation or fracture of the housing, deformation of the bearing, galling on fit surfaces, as well as resultant poor fit accuracy.**

For an application subjected to high running accuracy, bearings of high accuracy must be used with a shaft and a housing of higher dimensional accuracy so as not to require a large interference Applying a large interference would cause the shaft or housing profile to be transferred to the bearing track, which could then interfere with the bearing running accuracy.

Table 6.1 Radial load and bearing fit

Bearing running conditions	Sketch	Load characteristic	Bearing fit	
			Inner ring	Outer ring
Inner ring : Rotation Outer ring: static Load direction: constant		Rotating inner ring load	Needs to be tight fit	May be loose fit
Inner ring: static Outer ring: rotation Load direction: rotating with outer ring		Static outer ring load		
Inner ring: static Outer ring: rotation Load direction: constant		Rotating inner ring load	May be loose fit	Needs to be tight fit
Inner ring: rotation Outer ring: static Load direction : rotating with inner ring		Static outer ring load		
Inner ring: rotation or static Outer ring: rotation or static Load direction: The direction can not be fixed.	Load direction is non-constant due to directional fluctuation, unbalanced load, etc.	Directionally unstable load	Needs to be tight fit	Needs to be tight fit

6.4 Recommended fits

The dimensional tolerances for the diameter of a shaft and the bore diameter of a bearing housing, on/in which a bearing is installed, are standardized under the metric system in ISO 286 and JIS B 0401 (Bases of tolerances, deviations and fits). Hence, bearing fits are determined by selection of the dimensional tolerances for shaft diameter and housing bore diameter as applicable.

Table 6.2 shows the recommended fits for the machined ring needle roller bearings (with inner ring) that are generally selected based on the dimensional and load conditions. **Table 6.3** shows the numerical fit values.

For the recommended fits for others than the machined ring needle roller bearings, refer to "Commentary" described in the respective Dimension Tables.

Table 6.2 General standards for fits of machined ring needle roller bearing (JIS Class 0, Class 6)

Table 6.2 (1) Tolerance range classes for shaft (recommended)

Conditions			Tolerance range class
Load characteristic	Load magnitude	Shaft diameter d mm	
Rotating inner ring load or directionally unstable load	Light load	— 50	j5
	Ordinary load	— 50	k5
		50 — 150	m5
		150 —	m6
	Heavy load and shock load	— 150	m6
		150 —	n6
Inner ring static load	Medium- and low-speed rotation, light load	All dimensions	g6
	General application		h6
	When high rotational accuracy is required		h5

Table 6.2 (2) Tolerance range classes for housing bore (recommended)

Conditions		Tolerance range class
Outer ring static load	Ordinary and heavy load	J7
	Two-split housing, ordinary load	H7
Rotating outer ring load	Light load	M7
	Ordinary load	N7
	Heavy load and shock load	P7
Directionally unstable load	Light load	J7
	Ordinary load	K7
	Heavy load and shock load	M7
When high rotational accuracy under light load is required		K6

Remarks: Light load, ordinary load and heavy load are classified per the following criteria.
Light load : $P_r \leqq 0.06C_r$
Ordinary load : $0.06C_r < P_r \leqq 0.12C_r$
Heavy load : $P_r > 0.12C_r$

6.5 Lower limit and upper limit of interference

When an intended bearing application requires an interference on the bearing, determine the appropriate interference taking into account the following considerations:

- Determine the lower limit taking into account the following factors:
  (1) Reduction in interference due to radial load
  (2) Reduction in interference due to temperature difference
  (3) Reduction in interference due to poor roughness on fit surfaces
- Recommended upper limit is 1/1000 as large as the shaft diameter or smaller.

The formulas for calculating the required interference are presented below:

(1) Radial load and required interference

When a radial load acts on a bearing, the interference between the inner ring and shaft will decrease. The interference required to maintain an effective interference can be determined by **formulas (6.1)** and **(6.2)** below:

For $F_r \leqq 0.3\ C_{0r}$,

$$\Delta d_F = 0.08\sqrt{\frac{d \cdot F_r}{B}}\ \left(0.25\sqrt{\frac{d \cdot F_r}{B}}\right) \cdots\cdots\cdots \textbf{(6.1)}$$

For $F_r > 0.3\ C_{0r}$,

$$\Delta d_F = 0.02\frac{F_r}{B}\ \left(0.2\frac{F_r}{B}\right) \cdots\cdots\cdots \textbf{(6.2)}$$

Where,
Δd_F : Required effective interference mm
d : Bearing bore diameter mm
B : Inner ring width mm
F_r : Radial load N (kgf)
C_{0r} : Basic static load rating N (kgf)

Remarks: Fit symbols “L” and “T” represent bearing clearance and interference respectively.

(2) Temperature difference and required interference

Heat is generated in a running bearing, and temperature difference occurs across the inner ring and outer ring: as a result, the interference between the inner ring and shaft will decrease. When the difference between bearing temperature and ambient temperature is taken as ΔT, the interference needed for maintaining an effective interference can be determined by **formula (6.3)**:

$$\Delta d_F = 0.0015 \cdot d \cdot \Delta T \quad \cdots\cdots \textbf{(6.3)}$$

Where,
- Δd_T : Required effective interference for temperature difference μm
- ΔT : Difference between bearing temperature and ambient temperature ˚C
- d : Bearing bore diameter mm

(3) Fitting surface roughness and required interference

The fitting surface is smoothed (surface roughness is made less) by bearing fits so that the interference reduces correspondingly. The interference reduction differs depending on the fitting surface roughness and generally the following reduction values must be used.

For ground shafts : 1.0 to 2.5mm
For lathe-turned shafts : 5.0 to 7.0 mm

(4) Maximum interference

Tensile stress or compressive stress occurs on a bearing ring that has been installed to a shaft or housing with possible interference between these members. Excessively large interference can cause the bearing ring to fracture or shorten the fatigue life of the bearing. Therefore, usually **set the maximum allowable interference at 1/1000 as large as the shaft diameter or smaller; or such that the maximum circumferential tensile stress occurring on the fitting surfaces is not greater than 130 MPa** (refer to **Table 6.4**).

(5) Stress and deformation caused by interference

When bearing ring (solid) is fitted with interference, it deforms elastically and this elastic deformation results in stress.(See **Fig.6.1**) The fitting surface pressure of bearing ring, circumferential tensile stress (inner ring), compressive stress (outer ring) and radial expansion of raceway (inner ring), and shrinkage(outer ring) can be calculated from **Table 6.4**.

Table 6.4 Deformation and stress caused by bearing fit

Item	Inner ring	Outer ring
Surface pressure p MPa	$p_i = \frac{E}{2}\,\frac{\Delta d_{eff}}{d}\,\frac{(1-k^2)(1-k_0^2)}{1-k^2k_0^2}$	$p_e = \frac{E}{2}\,\frac{\Delta D_{eff}}{D}\,\frac{(1-h^2)(1-h_0^2)}{1-h^2h_0^2}$
Circumferential maximum stress σ MPa	$\sigma_i = p_i\,\frac{1+k^2}{1-k^2}$ (Tensile stress)	$\sigma_e = p_e\,\frac{2}{1-h^2}$ (Compressive stress)
Radial elastic deformation of raceway Δ	$\Delta_i = \Delta d_{eff}\cdot k\,\frac{1-k_0^2}{1-k^2k_0^2}$ (Expansion)	$\Delta_e = \Delta D_{eff}\cdot h\,\frac{1-h_0^2}{1-h^2h_0^2}$ (Shrinkage)

Where,

$$k = \frac{d}{d_i},\quad k_0 = \frac{d_0}{d},\quad h = \frac{D_e}{D},\quad h_0 = \frac{D}{D_0}$$

Remarks (Symbol representation)
- d : Inner ring bore diameter (shaft diameter) mm
- d_0 : Hollow shaft bore diameter (For solid shaft, $d_0 = 0$) mm
- d_i : Inner ring raceway diameter mm
- Δd_{eff} : Effective interference for inner ring mm
- D : Outer ring outer diameter (housing hole diameter) mm
- D_0 : Housing outer diameter (For sufficient housing size, $D_0 = \infty$) mm
- D_e : Outer ring raceway diameter mm
- ΔD_{eff} : Effective interference for outer ring mm
- E : Modulus of elasticity (Young factor) 2.07×10^6 (21200) MPa (kgf/mm²)

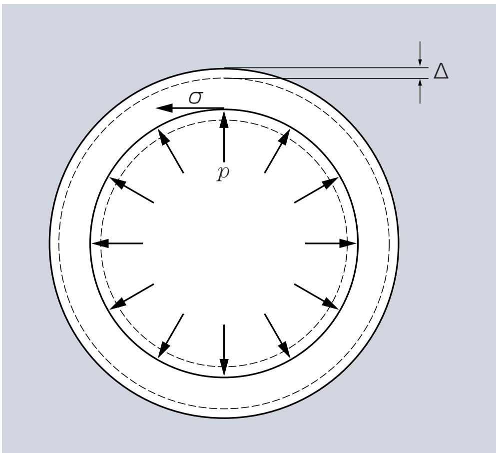

Fig.6.1

7. Limiting Speeds

At a higher bearing running speed, the bearing temperature will be higher due to frictional heat generated inside the bearing, possibly leading to failures such as seizure. As a result, the bearing will fail to continue stable operation. A maximum running speed that allows a bearing to run without developing such a problem heat buildup is known as **limiting speed** (min^{-1}) and can vary depending on the bearing type, dimensions, cage type, load, acceleration/deceleration conditions, lubrication conditions and cooling conditions.

As a guideline, each bearing dimension table contains data about limiting bearing speeds obtained from grease lubrication and oil lubrication. However, it should be noted that these values are based on the following assumptions:

- Bearing that has been manufactured per NTN standard design specification and is provided with an appropriate internal clearance has been correctly mounted.
- Bearing is lubricated with a good quality lubricant, which is resupplied and replaced at correct intervals.
- Bearing is operated under ordinary loading conditions ($P \leqq 0.09\ C_r$) and at an ordinary operating temperature.

If the user is thinking of a bearing application whose running speed exceeds the limiting speed in the relevant dimension table, the user has to adopt a bearing that satisfies stricter requirements for cage specification, internal clearance, bearing accuracy, etc. and make special considerations which typically include adoption of forced circulating lubrication system.

8. Shaft and Housing Design

Even if the bearing to be used is selected correctly, it can not fulfill its specific function unless the shaft/housing on/in which it is installed is designed correctly. For needle roller bearings, special attention must be paid to shaft and housing designs, since the bearing ring thickness is thinner compared to other rolling bearing types.

8.1 Design of bearing installing portions

For needle roller and cage assemblies, attention must be paid to the axial guidance surface, such as a shaft shoulder. This guiding surface should be smooth and free from burrs. Under challenging load and/or speed conditions, a hardened and ground surface is required.

In cases where a snap ring is used as a locating shoulder (**Fig. 8.1**), a thrust ring should be used between the snap ring and bearing cage to prevent the cut section of the snap ring from contacting the cage directly. **NTN** offers WR type snap rings that are customdesigned for axial retention of needle roller & cage assemblies. (Refer to the Dimensions Table on page B-267.)

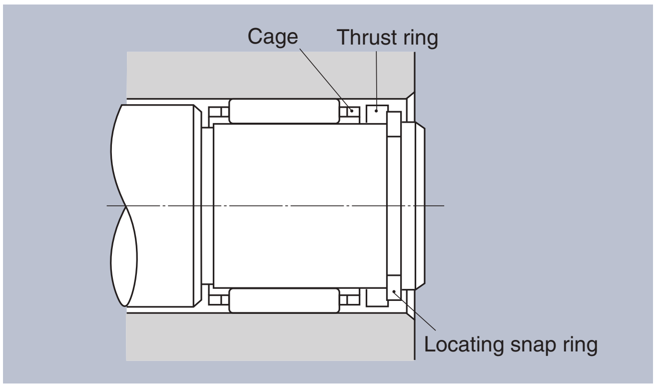

Fig. 8.1 Bearing fixing by thrust ring

Since a radial needle roller bearing can move freely on the shaft along the axial direction, a ball bearing or thrust bearing is used on the side opposite to the radial needle roller bearing in order to locate the shaft in the axial direction. With an application where the axial load is low and the running speed is not high (for example, an idle gear in gearbox), a thrust ring may be installed to a shaft as shown in **Fig. 8.2** to form a sliding bearing between the thrust ring and the housing end face in order to axially position the bearing. **Fig.8.3** illustrates an example of the above thrust ring with oil groove on its guide surface. The boundary between this oil groove and the plane area must be chamfered for deburring.

In general, for proper installation of needle roller bearing the inner ring and outer ring are both positioned in axial direction so that the bearing displaces in axial direction while running.

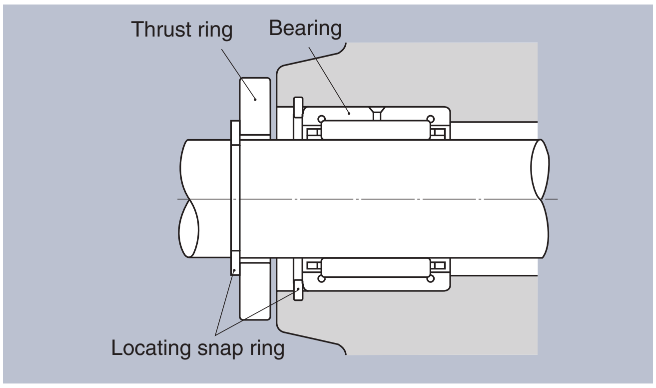

Fig. 8.2 Bearing fixing in axial direction

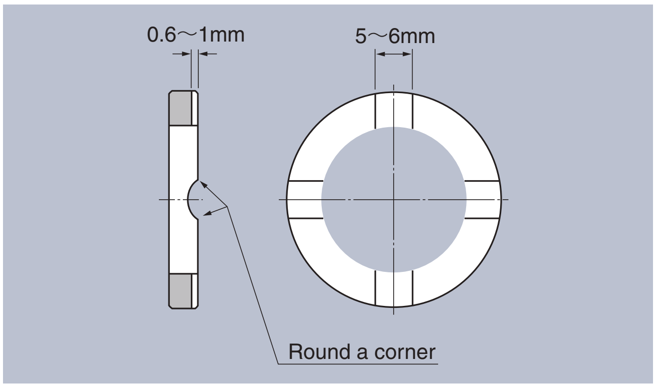

Fig. 8.3 Design of thrust ring guide surface

(1) Inner ring

For fixing inner ring correctly on a shaft, the shaft shoulder face is finished at the right angle against the shaft axial center and, in addition, the shaft corner radius must be smaller than the inner ring chamfer dimension.

To simplify inner ring extraction work, cutout grooves for engagement with jaws of an extraction jig are formed at the shoulder of the shaft as shown in **Fig. 8.4**, and the inner ring is extracted with the extraction jig according to a method illustrated in **Fig. 8.5**. Furthermore, for facilitating inner ring pull-out work the shaft shoulder is provided with a notched groove,as illustrated in **Fig. 8.5**, to accept an inner ring pull-out jig (puller).

NTN snap ring WR type for shaft use (Refer to Dimensions Table on page B-267) can be used for simply fixing inner ring in axial direction. (**Fig. 8.6**) Moreover,

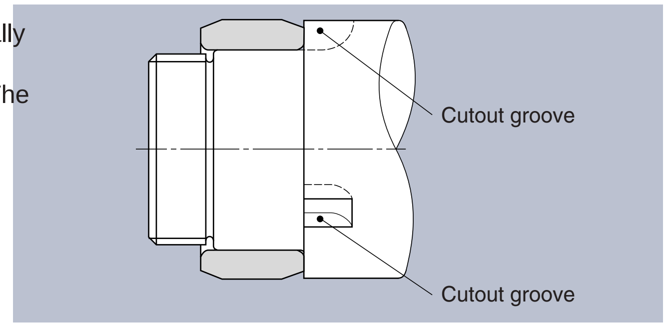

Fig. 8.4 Cutout groove for inner ring extraction

inner ring can be fixed in axial direction using an end plate or a side ring as illustrated in **Figs. 8.7** and **8.8**.

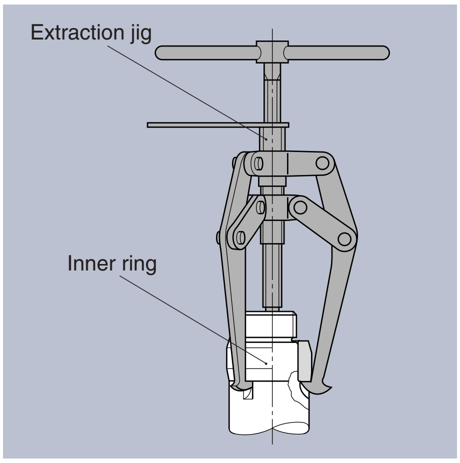

Fig. 8.5 Inner ring extraction with extraction jig

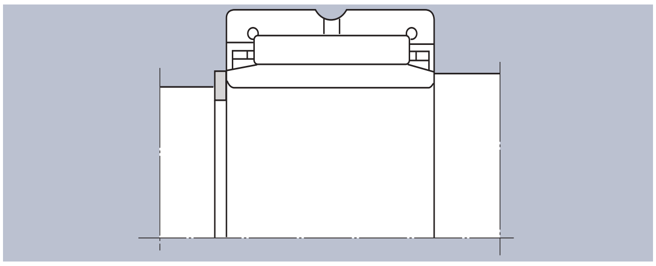

Fig. 8.6 Inner ring fixing method with snap ring

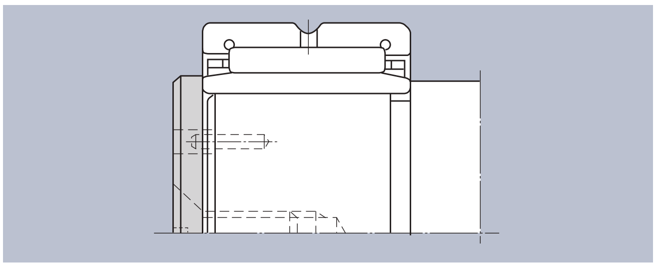

Fig. 8.7 Inner ring fixing method with end plate

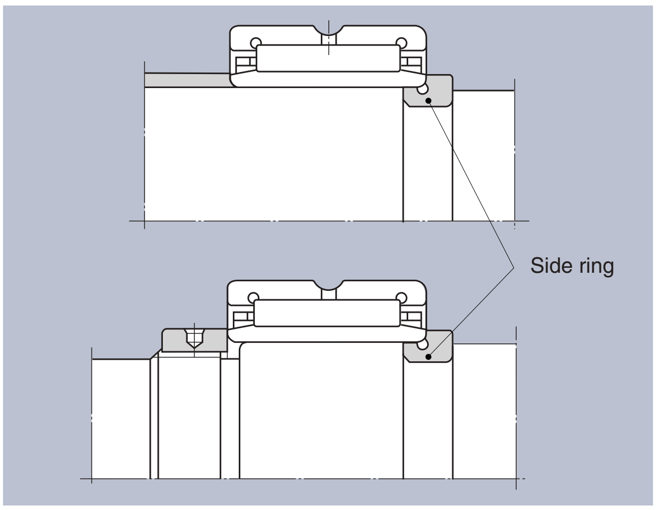

Fig.8.8 Inner ring fixing method with side ring

(2) Outer ring

Similarly to Para. 8.1(1) "Inner Ring", good care must be exercised of the shoulder profile of bearing housing for fixing outer ring in axial direction.

Figs. 8.9 and **8.10** illustrate the methods of fixing outer ring in axial direction.

For the outer ring also, the **NTN** snap ring type BR for housing (refer to the dimension table in page B-269) can be used. **NTN** BR type snap rings are designed to the dimensions adaptable to the needle roller bearings with low section height. However, commercially available snap rings conforming to JIS standard as applicable can also be used for the same bearings with adequately high section height.

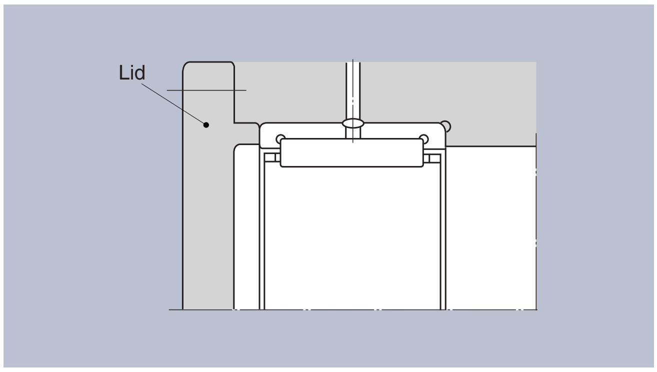

Fig. 8.9 Outer ring fixing by lid

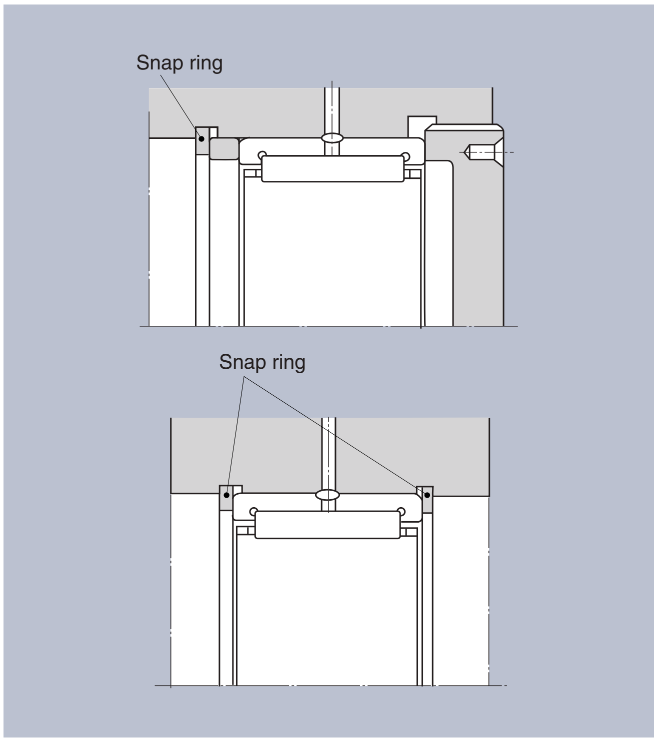

Fig. 8.10 Outer ring fixing method with snap ring

8.2 Bearing fitting dimensions

8.2.1 Shoulder height and corner roundness

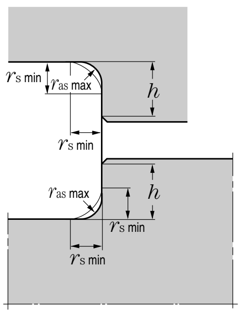
The respective shoulder heights "h", of the shaft and housing are designed to be larger than the maximum bearing chamfer dimension $r_{s\,max}$, so the bearing end face comes in contact with the flat zone. The corner roundness "r_{as}" is designed to be smaller than the minimum bearing chamfer dimension "$r_{s\,min}$" so as not to interfere with the bearing. Generally the radius of the shaft and housing corner roundness shown in **Table 8.1** is used as the shoulder heights of the shaft and housing.

The dimensions of the shafts and housings related to bearing installation are as described in the dimensions table for each bearing type. The shoulder diameter shown in this table means the effective shoulder diameter which comes in contact with the side face of bearing excluding the chamfered portion of the shoulder.

Table 8.1 Radius of shaft /housing corner roundness and shoulder height

Unit mm

$r_{s\,min}$	$r_{as\,max}$	h (min)
0.15	0.15	0.6
0.2	0.2	0.8
0.3	0.3	1
0.6	0.6	2
1	1	2.5
1.1	1	3.25
1.5	1.5	4
2	2	4.5
2.1	2	5.5
2.5	2	5.5
3	2.5	6.5
4	3	8



8.2.2 Applications of spacer and relief grinding

There may be cases where corner roundness $r_{as\,max}$ needs to be greater than the chamfering dimension on the bearing in order to mitigate stress concentration and enhance shaft strength (**Fig. 8.11a**), or where sufficiently large contact area is not available because of a low shaft shoulder (**Fig. 8.11b**). Then, a spacer can be inserted between the shaft shoulder and bearing.

Dimensions of ground-finished fit surfaces on shafts and housings are listed in **Table 8.2**.

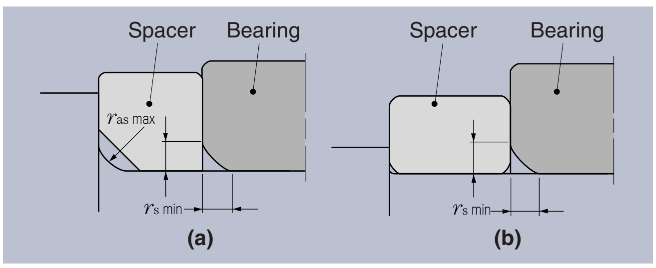


Fig. 8.11 Spacer applications

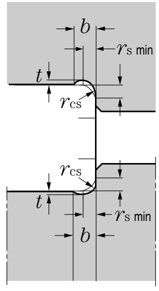
Table 8.2 Relief grinding dimension for shaft and housing corners

Unit mm

$r_{s\,min}$	b	t	r_{cs}
1	2	0.2	1.3
1.1	2.4	0.3	1.5
1.5	3.2	0.4	2
2	4	0.5	2.5
2.1	4	0.5	2.5
3	4.7	0.5	3
4	5.9	0.5	4



8.2.3 Mounting dimensions for thrust bearings

To be able to satisfy requirements for load capacity and rigidity, the surface of bearing ring on any thrust bearing needs to be sufficiently large. Therefore, the mounting dimensions in the dimension table for the intended bearing needs to be satisfied (**Fig. 8.12**).

Because of this, shoulder heights for thrust bearings have to be greater compared to radial bearings. (For the mounting dimensions of a particular thrust bearing, refer to the dimension table for that bearing.)

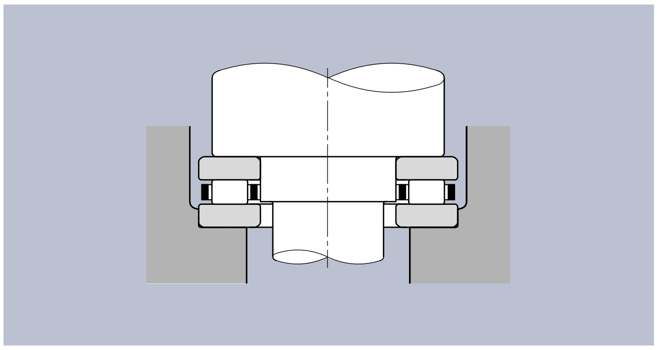


Fig. 8.12

8.3 Shaft and housing accuracy

The bearing ring of a needle roller bearings is thin-walled. Consequently, degree of physical accuracy of the raceway surface of the bearing ring is governed by physical accuracy of the fit surface of the shaft or housing to which the intended bearing is installed.

Table 8.3 summarizes recommended physical accuracy (tolerances) on the fit surfaces of the shaft and housing under ordinary bearing operating conditions: the characteristics in question are dimensional accuracy, shape accuracy, surface roughness, and runout of the shaft shoulder relative to fit surface.

For an application that adopts a double-split housing, the bore side of each housing half may be relieved: consequently, when the housing halves are joined together and the mating surfaces are forced together, resultant deformation on the outer ring is minimal.

Table 8.3 Shaft and housing accuracy (recommended)

Characteristic item	Shaft	Housing
Dimensional accuracy	IT6 (IT5)	IT7 (IT6)
Roundness cylindricality (max)	IT3	IT4
Shoulder perpendicularity (max)	IT3	IT3
Fitting surface roughness	0.8a	1.6a

Remarks: The parenthesized values are applied to the bearings of accuracy class 5 and higher.

8.4 Raceway surface accuracy

For needle roller bearings, the shaft and housing are used as the raceway surface on applications. The raceway dimensional accuracy, profile accuracy and surface roughness of the shaft/housing must be equivalent to the raceway accuracy of the bearing itself. **Table 8.4** shows the specified surface accuracy and surface roughness of the shaft/housing raceway.

Table 8.4 Raceway surface accuracy (recommendation)

Characteristic item	Shaft	Housing
Dimensional accuracy	IT5 (IT4)	IT6 (IT5)
Roundness cylindricality (max)	IT3 (IT2)	IT4 (IT3)
Shoulder perpendicularity (max)	IT3	IT3
Surface roughness	For shaft diameter of φ80 and less :0.2a For shaft diameter of over φ80 to 120 :0.3a For shaft diameter of over φ120 :0.4a	

Note) The parenthesized values are applied where high rotational accuracy is required.

8.5 Material and hardness of raceway surface

When the outer surface or bore surface of the shaft(hollowed) or housing is used as raceway, it must be hardened to HRC58 to 64 in order to obtain sufficient load capacity. For that, the materials shown in **Table 8.5** are used after heat-treated properly.

Table 8.5 Materials used for raceway

Kinds of steel	Representative example	Related standards
High carbon chrome bearing steel	SUJ2	JIS G 4805
Carbon tool steel	SK85 (previously: SK5)	JIS G 4401
Nickel chrome molybdenum steel	SNCM420	JIS G 4053 (previously: JIS G 4103)
Chrome steel	SCr420	JIS G 4053 (previously: JIS G 4104)
Chrome molybdenum steel	SCM420	JIS G 4053 (previously: JIS G 4105)
Stainless steel	SUSU440C	JIS G 4303

When steel is surface-hardened by carburizing or carbonitriding, JIS Standard defines the depth from surface up to HV550 as an effective hardened layer. The minimum value of effective hardened layer depth is approximately expressed in **formula (8.1)**.

$$E_{ht\ min} \geqq 0.8D_w (0.1+0.002D_w) \quad \cdots\cdots\cdots\cdots \textbf{(8.1)}$$

Where,

$E_{ht\ min}$: Minimum effective hardened layer depth mm

D_w : Roller diameter mm

8.6 Allowable bearing inclination

The inner ring and outer ring of the bearing incline a little eventually against one another depending on shaft deflection, shaft /housing machining accuracy, fitting deviation, etc. Although this allowable inclination differs depending on bearing type, bearing load, internal clearance, etc., the inclination degree shown in **Table 8.6** must be used as a guideline in the case of general applications because even minor inclination of the inner and outer ring could cause a reduction of bearing life and damage the cage.

Table 8.6

Bearing type	Allowable inclination
Radial needle roller bearing	1/2 000
Thrust bearing	1/10 000

9. Lubrication

9.1 Purpose of lubrication

When a bearing is lubricated, its rolling and sliding surfaces are covered with a thin oil film that prevents the occurrence of metal-to-metal contact. Lubrication of rolling bearings offers the following benefits:

(1) Reduction of friction and wear
(2) Discharge of friction heat
(3) Further extension of bearing life
(4) Rust prevention
(5) Prevention of foreign matter invasion

To fully realize these benefits developed, the bearing user has to adopt a lubrication system that best suits the projected bearing operating conditions, select quality lubricant, and adopt a relevant sealing design that helps regulate the amount of lubricant retained, prevent the ingress of foreign materials and leakage of the lubricant.

9.2 Lubrication systems and characteristics

In general, bearing lubrication systems usually available as grease lubrication and oil lubrication, each featuring unique advantages and disadvantages. The user needs to select an appropriate lubrication system that best suits the user's bearing performance requirements.

Table 9.1 summarizes the different features of grease and oil lubrication.

Table 9.1 Characteristic comparison of grease and oil lubrication

Lubrication method / Comparative items	Grease lubrication	Oil lubrication
Handling	◎	△
Reliability	○	◎
Cooling effect	×	○ (Recirculation needed)
Seal structure	○	△
Power loss	○	○
Environmental pollution	○	△
High speed operation of bearing	×	○

◎ : Extraordinarily advantageous ○ : Advantageous
△ : Fairly advantageous × : Disadvantageous

9.3 Grease lubrication

Grease lubrication is the simplest lubrication method. This method enables a simplified design of the seal structure, and is broadly used.

Important points for this lubrication method are to select an optimum grease and to fill it securely in the bearing. Particularly where the cage is guided by the inner ring or outer ring of bearing, care must be exercised so the guide surface is fully greased throughout its entire area.

If requiring refilling of grease, the bearing should be provided with grease sectors as a refilling means and a grease valve or an equivalent as a means of discharge.

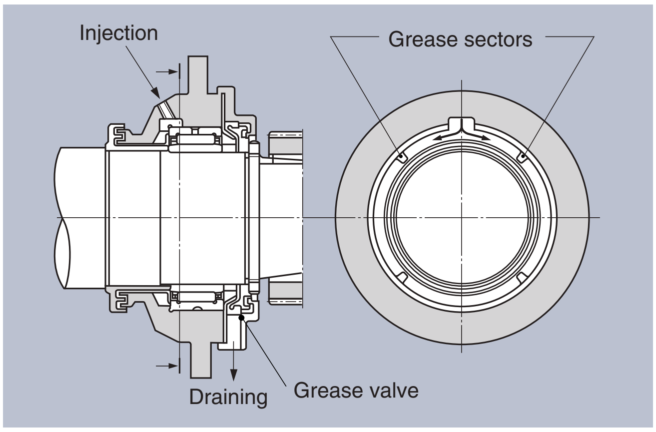

Fig. 9.1 An example of bearing unit with grease sector and grease valve

Fig. 9.1 illustrates an example of bearing unit with grease sector and a grease valve. An amount of grease injected through a port, such as a grease nipple, is blocked by the grease sectors, then fills the space and the excess fluid flows into the bearing. Grease is circulated through the interior of bearing, and excess amount of grease pushed out of the bearing is allowed to drain through the grease valve.

9.3.1 About grease

Grease lubrication is **composed of a lubrication base oil (ex. mineral oil base or a synthetic oil base) held with a thickener, and various additives added thereto.** The properties of grease are determined by the kinds and combination of base oil, thickener, and additives.

Commons grease types and their characteristics are summarized in **Table 9.2**. Characteristics of greases of a similar type can vary greatly depending on the brands. Therefore, **to be able to select an optimal grease brand, it is necessary to check grease characteristic data, available from grease manufacturers.**

(1) Base oil

Base oils used in grease are **mineral oil**, or synthetic oils such as **ester** and **ether oil**.

Lubricating performance of a given lubricant is mainly governed by lubricating performance of the base oil. Generally, greases comprising a low-viscosity base oil excel in low-temperature characteristics and high-speed performance, while greases with a high-viscosity base oil boast excellent high-temperature, high-load characteristics.

(2) Thickener

Thickeners are blended and diffused in base oil to hold grease in a semi-solid form. Commonly used thickeners include: metal soaps derived from **lithium**, **sodium** and **calcium**; non-metal soap thickeners made from inorganic materials such as **silica gel** and **bentonite**, and organic materials such as **urea** and **fluoro carbon**. The grease characteristics such as **critical operating temperature, mechanical stability, durability**, etc. are mainly

Table 9.2 Grease varieties and characteristics

Grease name	Lithium grease			Sodium grease (Fiber grease)	Calcium compound base grease	Aluminum grease	Non-soap grease	
Thickener	Li soap			Na soap	Ca+Na soap Ca+Li soap	Al soap	Bentone, silica gel, urea, carbon black, etc.	
Base oil	Mineral oil	Diester oil	Silicone oil	Mineral oil	Mineral oil	Mineral oil	Mineral oil	Synthetic oil
Dropping point ˚C	170〜190	170〜190	200〜250	150〜180	150〜180	70〜90	250 or more	250 or more
Operating temperature range ˚C	−30〜+130	−50〜+130	−50〜+160	−20〜+130	−20〜+120	−10〜+80	−10〜+130	−50〜+200
Mechanical stability	Excellent	Good	Good	Excellent to good	Excellent to good	Good to poor	Good	Good
Pressure resistance	Good	Good	Poor	Good	Excellent to good	Good	Good	Good
Water resistance	Good	Good	Good	Good to poor	Good to poor	Good	Good	Good
Applications	Broadest application. Grease for universal type rolling bearings.	Excellent in low temperature characteristic and anti-friction characteristic.	suited to high temperature and low temperature. Low oil film strength and unsuitable for high load application.	emulsified by inclusion of water content. Comparatively excellent in high temperature characteristic.	Excellent in water resistance and mechanical stability. Suitable for bearing subjected to shock load.	Excellent in viscosity characteristic. Suitable for bearing subjected to vibration.	Available for use in wide temperature range from low to high temperature. Some of non-soap base greases are excellent in heat resistance, cold resistance, chemical resistance, etc. subject to proper combination of base oil and thickener. Grease for universal type rolling bearings.	

Remarks: The operating temperature range in this table is the general characteristic value, not the guaranteed value.

determined by the kind of thickener used. Generally, water resistance of sodium soap grease is poor. Non-soap thickeners made from bentone and urea feature excellent high-temperature characteristics.

(3) Additives

Any greases contain various additives to improve the performance. For example: **oxidation inhibitors, extreme pressure additives** (EP additives), **rust inhibitors, corrosion inhibitors,** etc.

A grease containing extreme pressure additives is used for bearings subjected to high load or shock load. A grease containing oxidation stabilizer is used for bearing applications wherein the operating temperature is comparatively high and the grease is not replenished for a long time.

(4) Consistency

"Consistency" is an index showing the hardness or fluidity of grease. **The higher the numerical value, the harder the consistency.** Lubricants commonly used for lubrication of rolling bearings are those having NLGI consistency number 1, 2 or 3.

Table 9.3 shows the general relationship of grease consistency to application.

Table 9.3 Grease consistency

NLGI consistency No.		JIS (ASTM) 60-cycle mixed grease consistency	Application
0	Soft	355–385	For centralized greasing
1	↑	310–340	For centralized greasing
2		265–295	For general application, for tight-sealed bearing
3	↓	220–250	For general application, for high temperature
4	Hard	175–205	Special application

(5) Grease mixing

Mixing dissimilar greases will alter the characteristics of grease: for example, consistency will vary (usually, the grease mixture will be softer compared with original greases) and the permissible operating temperature will be lower. **Therefore, in principle, do not mix greases other than mixing of portions of same grease brand.**

Where mixing of different greases is inevitable, greases composed of the same thickener and similar base oil must be selected. Even when greases of the same kind are mixed together, the properties of the mixed grease could vary depending on difference in additives, etc. It is therefore necessary to check the property variation in advance.

9.3.2 Grease fill amount

Grease fill amount differs depending on housing design, available volume, rotational speed, kind of grease, etc.

As a guideline, approximately 50% to 80% of the static volume within a bearing and housing is filled with grease. When intending higher running speed, or wanting to limit temperature rise, fill grease sparingly. **Too much grease fill would cause the grease temperature to rise, which would then lead to reduction of the specific lubrication performance due to leak of the softened grease, or quality change such as oxidation, etc.**

9.3.3 Grease replenishment

A bearings grease must be replenished at proper intervals because its lubrication performance deteriorates with running time. This replenishing interval differs depending on bearing type, dimension, rotational speed, bearing temperature, kind of grease used, etc.

Fig.9.2 gives the replenishing interval chart as a guideline. This chart is subject to use of a grease for ordinary rolling bearings under usual operating conditions.

Needless to say, the grease replenishing interval must be shortened as the bearing temperature gets higher. As an approximate guideline, when the bearing temperature is 80˚C or more, the replenishing interval shall be shortened by 1/1.5 whenever the bearing temperature rises by 10˚C.

[Ex.] Let us determine grease replenishment intervals for NA4910R that is run at a speed of n=1600 min^{-1}. From the dimension table for **NA4910R**, the shaft diameter (bearing bore diameter)=d 50 mm, limiting speed no = 4700 min^{-1}

Accordingly,

$$\frac{n_0}{n} = \frac{4700}{1600} \fallingdotseq 2.9$$

Plot a line horizontally from d=50 point in **Fig. 9.2** and deem the intersection point with the vertical line Ⅰ as A. Thereafter, connect n_0/n=3 point B on the vertical line Ⅱ and said A point together, with a straight line, and determine the intersection point C with the vertical line Ⅲ.

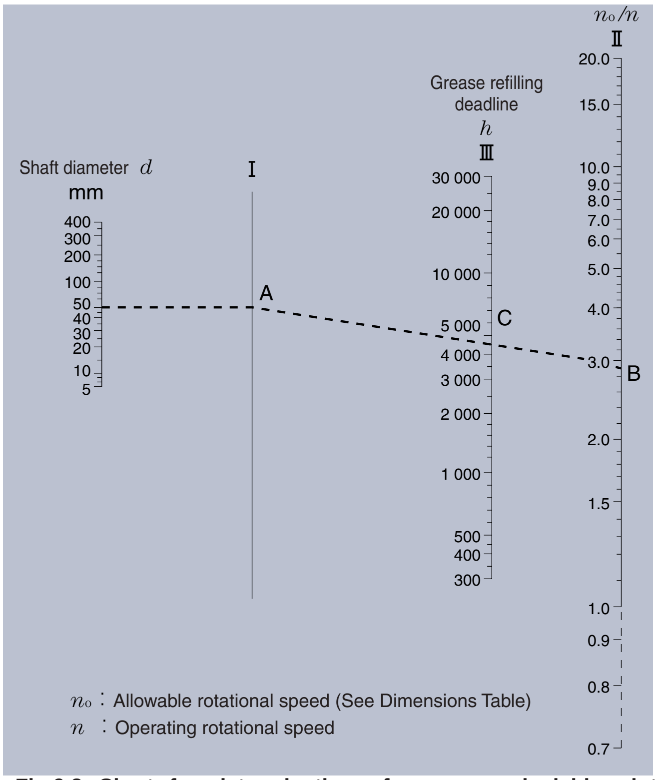

Fig.9.2 Chart for determination of grease replenishing interval

The grease replenishing interval of approximately 4600 hours can be read from the intersection point C.

9.3.4 Solid grease (lubricant for special "Polylube" bearings)

This unique solid grease consists of lubricating grease and ultra heavy molecular weight polyethylene (UHMW-PE) as main components. For more detailed information, refer to page A-54 in this document or the special catalog (Japanese only) "Polylube Needle Bearings" (NTN CAT. NO. 3605).

9.4 Oil lubrication

In general, oil lubrication is more suitable for high speed or high temperature applications than grease lubrication. Oil lubrication is suitable for the cases where heat generated in a bearing or heat transferred to a bearing must be discharged outside the bearing.

9.4.1 Lubrication method

(1) Oil bath lubrication

Oil bath lubrication is the most common lubrication scheme among various oil lubrication systems. It is used for low-speed and medium-speed bearing applications. An important point in this method is control of oil level in an oil bath.

For that, when bearings are installed on a horizontal shaft, it is common that a point close to the center of the rolling element in the lowest position should be deemed as the oil level to be secured during shutdown. In this case, the housing must be designed with such a profile as to minimize variation in oil level therein. Furthermore, it is desirable to provide the housing with an oil gauge to facilitate level check during running as well as shutdown.

When bearings are installed on a vertical shaft, it is okay if 50 to 80% of the rolling elements are dipped in an oil bath under low speed running, but in the cases of high speed running and bearings used in multiple rows it is desirable to adopt the drip lubrication and circulating lubrication methods, or others described hereunder.

(2) Spray lubrication

This method sprays lubrication oil by an impeller of simple structure, which is mounted on the shaft, without directly dipping a bearing in an oil batch. This can be applied to bearings running at considerably high speed.

(3) Drip lubrication

This lubrication method is used where bearing runs at comparatively high speed with medium and less loads act thereon. In this method, oil drips from an oiler on the top of a bearing unit, striking the rolling elements for atomizing lubrication (**Fig. 9.3**) and a small amount of oil passes through the bearing. In many cases the bearing is lubricated with several drips per minute though the number of oil drips per specific unit differs depending on bearing type and dimension.

(4) Circulating lubrication

This circulating lubrication method is adopted to cool down bearings or to lubricate by a centralized lubrication system. As added features with this method the oil feed line is equipped with a cooler to cool down the lubrication oil and an oil filter to purify the lubrication oil.

Under this circulating lubrication system, the lubrication oil must be discharged from each bearing after having passed through it. For that, it is important to provide an oil inlet and an oil outlet on each bearing in opposite position and to make the oil discharge port size as large as possible or otherwise to discharge the oil compulsorily. (**Fig.9.4**)

(5) Others

Jet lubrication, oil mist lubrication, air-operated oil lubrication, etc. are available as other lubrication methods.

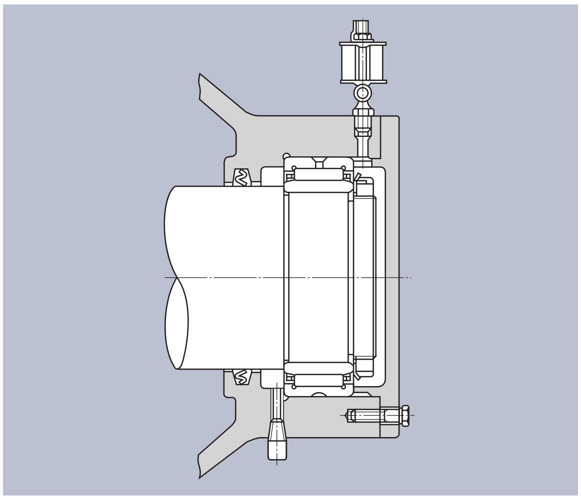

Fig. 9.3 Drip lubrication

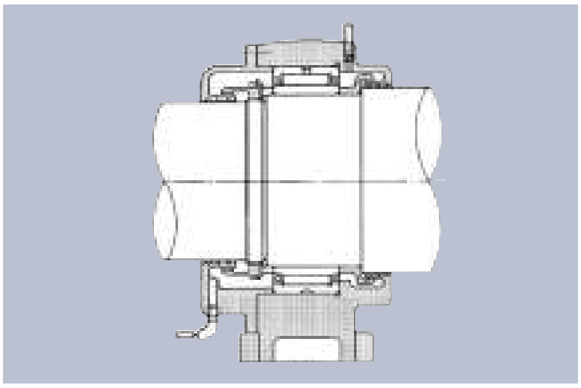

Fig.9.4 Circulating lubrication

9.4.2 Lubrication oil

To lubricate rolling bearings, mineral oil lubricants are often used, the examples of which include **spindle oil, machine oil** and **turbine oil**. When a rolling bearing is used in a demanding operating environment where the ambient temperature can be **not lower than 150˚C** or **not higher than -30˚C**, a rolling bearing should be lubricated with **synthetic oil** such as **diester oil, silicone oil** and **fluoro carbon oil.**

With lubrication oil, its viscosity is one of the important characteristics that determine the lubrication performance. Too low viscosity of lubrication oil causes imperfect forming of an oil film reading to damage of bearing surface, while too high viscosity of lubrication oil causes great viscosity resistance, which then leads to temperature rise and increase of friction loss.

Generally lubrication oil of lower viscosity is used for the faster rotational speed of bearing, while lubrication oil of higher viscosity is used for the heavier bearing loads.

A lubricant for a rolling bearing has to satisfy viscosity listed in **Table 9.4** at the operating temperature of that rolling bearing. **Fig. 9.5** shows the lubrication oil viscosity - temperature characteristic chart, which should be referred to when selecting a lubrication oil of optimal viscosity under actual operating temperature.

Furthermore, **Table 9.5** shows the criterion for selection of the lubrication oil viscosity according to the actual bearing operating conditions.

Table 9.4 Oil viscosity required for each bearing type

Bearing type	Required viscosity mm²/s
Radial needle roller bearing	13
Thrust needle roller bearing	20

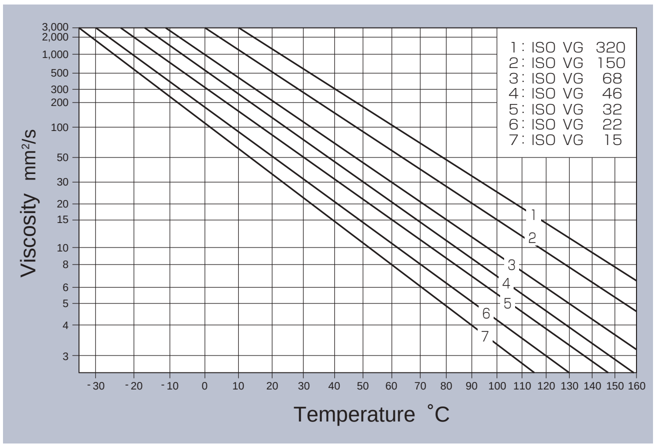

Fig. 9.5 Lubrication oil viscosity - temperature characteristic chart

Table 9.5 Criteria for selection of lubrication oil (Reference)

Bearing operating temperature ˚C	dn value	ISO viscosity grades for lubrication oil (VG)	
		Ordinary load	Heavy load or shock load
−30～0	up to allowable rotational speed	22 32	46
0～60	up to 15000	46 68	100
	15 000～80 000	32 46	68
	80 000～150 000	22 32	32
60～100	up to 15000	150	220
	15 000～80 000	100	150
	80 000～150 000	68	100 150
100～150	up to allowable rotational speed	320	

Remarks:
1. Subject to oil bath lubrication or circulating lubrication.
2. Apply to **NTN** for other operating conditions other than those specified in this Table.

9.4.3 Oil supply rate

When lubricating oil is force-fed into a bearing, the amount of heat generated in the bearing is equal to a sum of amount of heat diffused from the housing and amount of heat removed by lubricating oil.

A standard oil supply rate to be used as a guideline when using an ordinary housing can be determined by **formula (9.1)**. The amount of heat diffused can vary depending on the shape of housing. Therefore, for bearing operation on an actual machine, begin with an oil supply rate approximately 1.5 to 2 times as much as the value determined by **formula (9.1)**, and determine an optimal supply rate through a series of adjustment efforts. It may be convenient to perform calculations with an assumption that there is no heat radiation from the housing and all the heat generated is removed with the lubricating oil. In such a case, take the shaft diameter d = 0 and then determine the oil supply rate q.

$$Q = K \cdot q \quad \text{……………………………………………} \textbf{(9.2)}$$

Where,

Q: Oil supply rate per bearing assembly cm³/min

K: Coefficient governed by temperature rise with lubricating oil in operating mode (**Table 9.6**)

q: Oil supply rate determined from the chart cm³/min (**Fig. 9.6**)

9.4.4 Guideline for lubricating oil change

How often the lubricating oil needs to be changed varies depending on the factors including bearing operating conditions, amount of oil in the lubrication system, and lubricating oil type. As a guideline, perform oil change for an oil bath lubrication system approximately once a year if the oil temperature in the bath is regulated at 50˚C or lower, or at least every three months if the oil temperature in the bath reaches a range from 80 to 100˚C.

For a critical machine involving needle roller bearings, the user is recommended to monitor current lubrication performance of the lubricating oil and deterioration in oil cleanness at regular intervals to establish the user's unique oil change schedule.

Table 9.6 K value

Temperature of discharged oil – Temperature of supply oil ˚C	K
10	1.5
15	1
20	0.75
25	0.6

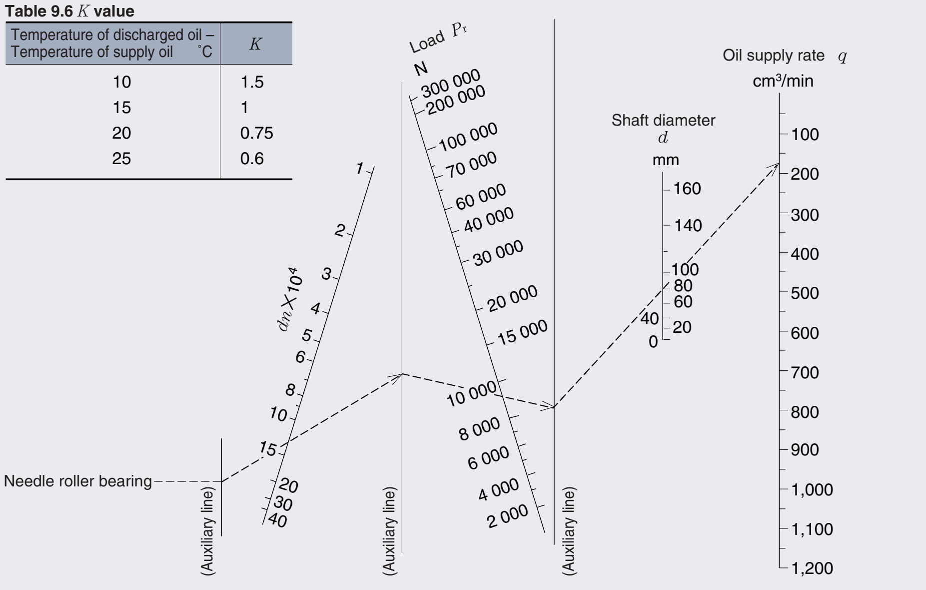

Fig. 9.6 Chart for determining oil supply rate

10. Sealing Devices

10.1 Non-contact seal and contact seal

The purpose of using a seal is to prevent a lubricant held in a bearing from leaking outside the bearing and to prevent powder, water content, etc. from invading into the bearing from outside.

It is very important to design a sealing device with full consideration of the operating conditions, lubricating condition, environmental condition, economical merit, etc., so that the bearing is not adversely affected by the sealing device during operation.

The bearing seals are mainly classified into non-contact seal, contact seal types. as shown in **Tables 10.1** and **10.2**, which must then be selected correctly according to each application,under full consideration of the characteristics of each sealing type.

Table 10.1 Seals (Non-contact seals)

	Non-contact seals		
Seal name	Oil groove seal Labyrinth seal (axial, radial)	Slinger seal	Air seal
Features	**<Oil groove seal>** This seal is fitted at either one side of a housing or a shaft, or fitted at the both sides for sealing In this case, this seal has an effect in preventing invasion of foreign matter from outside by retaining grease in the oil grooves. **< Labyrinth seal >** This seal having a high sealing effect due to its multiple labyrinths and long passage is mainly used for grease lubrication. Generally it is suited to a high speed bearing, but it has a dust-proofing effect even under low speed running if the seal grooves are filled up with grease. It is convenient if this seal is provided with a grease nipple.	In oil lubrication, this seal has an effect in slinging and returning the oil thrown out along its sleeve by centrifugal force if its sleeve is provided with projections. A seal example illustrated in **Fig. 10.6** prevents invasion of foreign matter from outside.	—
Application examples	 **Fig. 10.1 Oil groove seal**	 **Fig. 10.4 Slinger with projections**	
	 **Fig. 10.2 Axial labyrinth seal**	 **Fig. 10.5 Slinger intended for back flow of flown-out oil by centrifuge**	
	 **Fig. 10.3 Radial labyrinth seal**	 **Fig. 10.6 Slinger provided at outer side**	

Table 10.2 Seals (Contact seals)

	Contact seals	
Seal name	Seal ring (felt seal, etc.) O-ring, piston ring	Oil seal, V-shaped ring seal, mechanical seal
Features	**<O-ring seal>** This seal type seals a fluid by pressing its elastic body onto the sliding surface with a constant contact pressure. Generally the contact seals are better in sealing performance than the non-contact seals, but the friction torque and temperature rise are greater than those of the non-contact seals. **<Felt seal>** This is the simplest of the contact seals, which is mainly used for grease lubrication and suited to prevention of fine dust, but oil penetration and purging are occasionally unavoidable to some extent.	**< Oil seal >** This seal type intended to seal lubricant at the sliding portion between its lip and a shaft. The oil seal ia an effective seal and is the most frequently used. The lip must be oriented outward to prevent invasion of water content and foreign matter from outside and oriented inward to prevent lubricant from leaking out of the housing. Furthermore, another seal type with two or more lips is also available for preventing lubricant purge and dust contamination.
Application examples	 **Fig. 10. 7 Felt seal**  **Fig.10. 8 Z type grease seal**  **Fig. 10. 9 GS type grease seal**	 **Fig. 10.10 Oil seal**

10.2 Combined seals

Several seal types are used in combination for an application in an environment where dust, water components, etc. exist as well as for mechanical portions which cannot to be contaminated by lubricant leak.

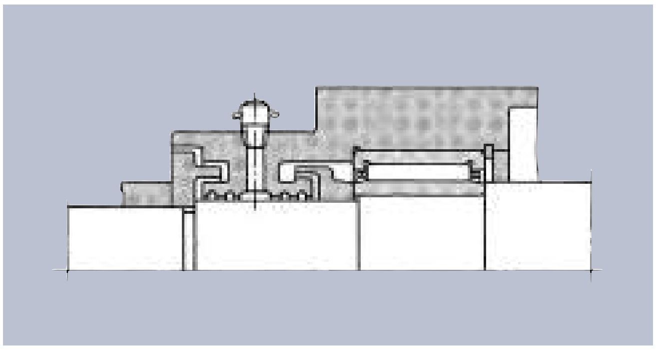

Fig. 10.11 Combined non-contact seal
Combination of labyrinth seal and oil groove seal

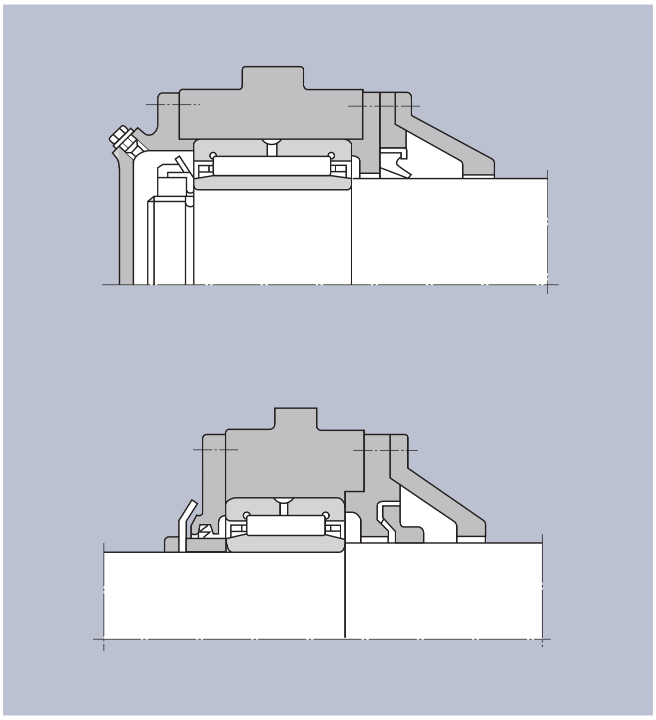

Fig. 10.12 Combined seal
Combination of contact seal and non-contact seal

10.3 Clearance setting

Oil groove seals and labyrinth seals have better sealing effects as the shaft - housing clearance gets smaller, but the actual clearance is generally selected from the following clearance values, under consideration of machining and assembling conditions, shaft deformation, etc.

Table 10.3 Clearances (Optional)

Seal type	Shaft diameter	Radial clearance	Axial clearance
Oil groove seal	50 or less	0.2～0.4	———
	Over 50 to 200	0.5～1.0	
Labyrinth seal	50 or less	0.2～0.4	1.0～2.0
	Over 50 to 200	0.5～1.0	3.0～5.0

10.4 NTN seals

Special-purposed **NTN** seals are available for needle roller bearings.(Refer to **Table 10.4** on page A-49.) For the more detailed information refer to the "Dimensions Table" on page B-273.

10.5 Seal materials and corresponding operating temperature ranges

The oil seal lip is ordinarily made of nitrile rubber, but acrylic rubber, silicone rubber and fluoro-rubber are used as the lip material depending on operating temperature, sealing objective, etc. **Table 10.5** shows the allowable operating temperature ranges available for the respective materials.

Table 10.5 Seal materials and corresponding operating temperature ranges (Reference)

Seal materials	Operating temperature ranges ˚C
Nitrile rubber	−25～+100
Acrylic rubber	−15～+130
Silicone rubber	−70～+150
Fluoro-rubber	−30～+180

10.6 Seal types and allowable speed

The allowable speed for the contact seal type depends on the surface roughness, accuracy and lubrication properties of sliding surface, operating temperature, etc. **Table 10.6** shows the allowable speed for each seal type, as a guideline.

Table 10.6 Seal types and corresponding allowable speed (Reference)

Seal types	Allowable speed m/s
Oil seal (nitrile rubber)	16 or less
Oil seal (acrylic rubber)	26 or less
Oil seal (fluoro-rubber)	32 or less
Z-grease seal (nitrile rubber)	6 or less
V-ring seal (nitrile rubber)	40 or less

Table 10.4 Seals (NTN contact seals)

Seal type	Contact seals (G type, GD type)
	Seal using mainly direct contact
Features	This seal type is a special-purposed seal for needle roller bearings which was designed for smaller section height. This is a synthetic rubber contact seal reinforced with steel plate, for use in the operating temperature range of -25 to +120˚C and, under continuous running condition, used at 100˚C or less. For applications under special operating conditions of greater than 120˚C, please contact contact **NTN** engineering.
Application examples	(see Fig. 10.13)

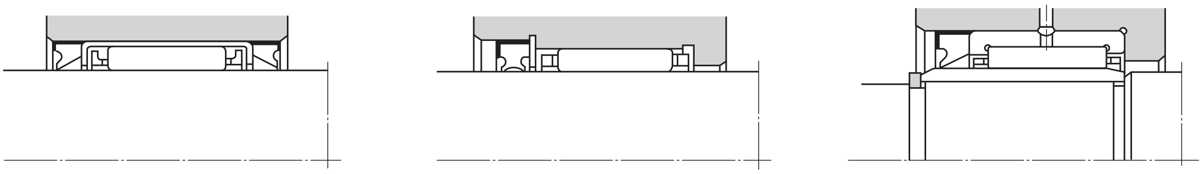

Fig. 10.13 Bearing sealing by NTN seals (Example)

10.7 Shaft surface roughness

Sealing performance and seal life depend on the surface roughness, accuracy and hardness of shaft sliding surface with which the seal lip comes in contact. **Table 10.7**shows the surface roughness as a guideline. For improved wear resistance of shaft surface it is desirable to maintain shaft surface hardness at least at HRC40 (HRC55 if possible) by heat treatment or hard chrome plating.

Table 10.7 Shaft surface hardness (Reference)

Speed m/s		Surface roughness
over	incl.	Ra
	5	0.8a
5	10	0.4a
10		0.2a

11. Bearing Handling

Bearings are precision parts. In order to preserve their accuracy and reliability, care must be exercised in their handling. In particular, bearing cleanliness must be maintained, sharp impacts avoided and rust prevented.

[1] Keep the bearing and other related parts clean
Foreign matters such as dust, moisture, etc. causes harmful effects on the life of the bearing. To avoid such harmful effects, bearings must be kept clean. In addition, tools, lubricants, washing oils, work environments, etc. must always be maintained in clean condition.

[2] Careful handling
Any shock to a bearing in handling could result in creating surface flaws and indentations of its raceway surface and rolling elements. In severe cases, cracking and chipping can occur. To avoid such defects, bearings must be handled with care.

[3] Use proper handling tools
Inappropriate tools should be avoided when installing and removing bearings.
Specific tools suited to the individual bearing types must be used. Special-purpose handling tools must be used particularly when installing a drawn cup needle roller bearing.

[4] Protect bearing from rusting
As a general rule, rust preventive oil is coated on all bearings. Direct handling of bearings should be avoided since the natural oil on hands can cause rusting of the bearings. To protect bearings from this type of rust, use a pair of gloves or coat mineral oil on the hands if directly handling the bearings with hands.

11.1 Bearing storage

Store bearings at room temperature with a relative humidity of 60% or less.

11.2 Washing

Never rotate a bearing with foreign matter within the raceway. This could result in damage to the raceway surfaces or rolling elements.
Therefore, any dismounted bearing is usually washed by light oil, kerosene or any other mild solvent to completely remove foreign matter.
In this case, two washing containers must be used: one for rough washing and another for finish washing.
Rough washing is done for removal of oil and foreign matter from bearings, while finish washing is done for fine washing of the roughly-washed bearing.
Further, any containers used for washing must be provided with a steel net in the center above the bottom of the container, as illustrated in **Fig. 11.1**, to prevent the bearing from coming in direct contact with the bottom of the container.
Furthermore, rust preventive treatment must be applied to the bearing immediately after washing, to protect it from corrosion.

<u>Do not rinse grease-prefilled bearings (shielded bearings, sealed bearings, one-way clutches, etc.). Otherwise, prefilled grease can wash away</u> or <u>deteriorate.</u>

<u>In addition, follow all applicable legal requirements such as environmental preservation, industrial labor safety laws, etc. and use the washing instructions provided by the detergent manufacturer and washing tank manufacturer</u>.

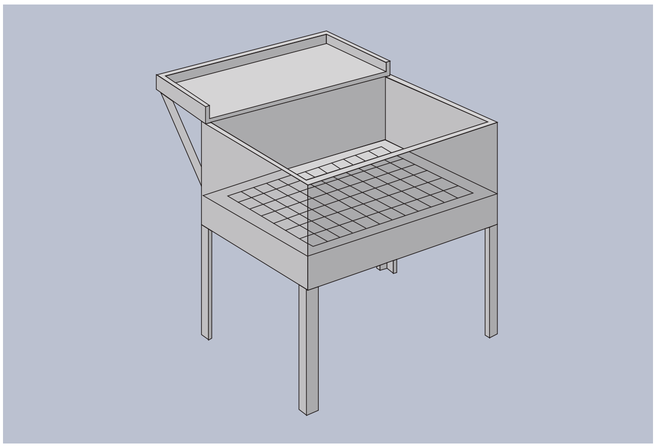

Fig. 11.1 Washing tank

11.3 Installation

Depending on bearing type and fitting conditions, the methods described below are used as a general method of installation. However, for installation of drawn cup needle roller bearings refer to Commentary given in the Dimensions Table.

(1) Preparations prior to installing
For the installation of bearings, it is desirable to prepare a clean and dry work place.
Contaminants, burrs, chips, etc. must be removed completely from all the parts related to a shaft and a housing before installing. Keep bearing in original packaging until ready for installation.
If the bearing is used in a grease-lubricated machine, it may be installed without removing the rust preventive oil coat on it. However, remove the rust preventive coat if the bearing is to be used with oil lubrication, or grease lubrication. Lubrication performance of the grease is jeopardized when mixed with the rust preventive agent. Use uncontaminated cleaning oil to remove the rust preventive agent coat and then allow the cleaning oil to dry or thoroughly wipe it away. Only then, install the bearing.
Do no to wash shield type and seal type bearings and one-way clutches.

(2) Interference-fit with a mechanical or hydraulic press

In general, the press-fit method using a press machine is used for the installation of bearings. The bearing ring (inner ring or outer ring) is press-fitted slowly via a backing strip as illustrated in **Fig. 11.2. Do not apply the press force to a bearing through its rolling elements. See example illustrated in Fig. 11.3.**

Further, a small bearing with minimal interference may be installed by hammering the bearing ring with a plastic hammer or similar tool. **In that case, however, the uniform hammering force must be applied to the bearing side face via the backing strip as illustrated in Fig. 11.2, because direct hammering to the bearing end face or partial hammering by use of a punch could impair the specific bearing performance.**

While installing a bearing, NEVER hit the outer ring with a hard tool such as a hammer to fit the inner ring over the shaft. Never hammer the inner ring to install the bearing to the shaft. Otherwise, a flaw and/or dent mark may occur on the raceway surface and rolling elements of the bearing. Also, coating the fitting surfaces with high-viscosity oil will help reduce friction on the fitting surfaces.

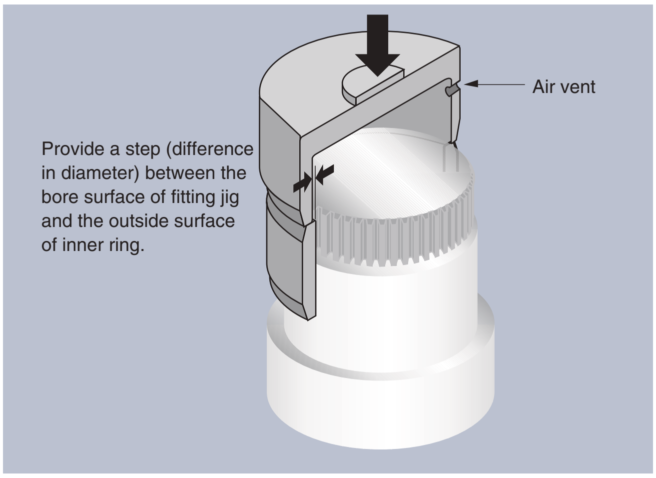

Fig. 11.2 Press-fitting of inner ring

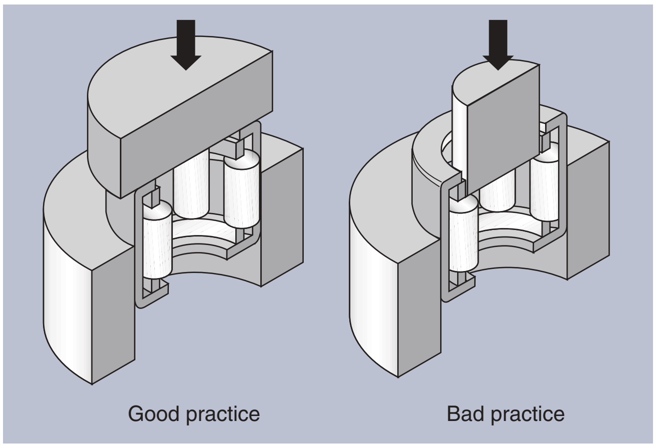

Fig.11.3 Good practice for press-fitting

(3) Shrink fit

This method too, is often used to install a bearing onto a shaft. The inner ring is heated in a medium such as a clean oil bath to expand its bore and is then fitted over the shaft. The oil used for this process should be pure mineral oil as it is less corrosive. The inner ring fitted onto the shaft is then allowed to stand to cool down. During the cool-down period, the inner ring shrinks in the axial direction too: therefore, the inner ring should be kept forced toward the shaft shoulder until it is fully cool in order to avoid a gap between it and the shaft shoulder. **Fig. 11.4** graphically illustrates the relationship between the expansion of the inner ring bore and the heating temperature. **Remember, however, that the inner ring must not be heated in excess of 120˚C. Also, do not apply shrink fit technique to a bearing with prefilled grease, or a bearing with a shield or seal.**

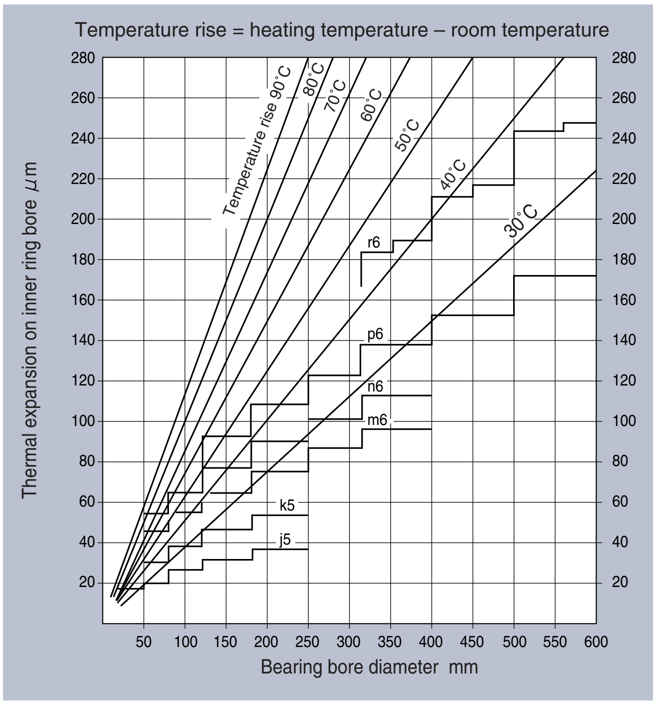

Fig. 11.4 Temperature rise needed for successful shrink fitting for inner ring

11.4 Bearing running test

To ensure that the bearing has been properly installed, a running test is performed after mounting.

Avoid running the bearing at its rated speed immediately after its installation. Otherwise, the bearing can fail if it has been incorrectly installed, or can seize if it is poorly lubricated. The shaft or housing should first be rotated by hand. If turning the shaft manually has proved to be problem-free, turn it at low speed with no load, and gradually increase the running speed and load while monitoring smoothness of bearing operation.

Carefully monitor noise and heat buildup on the running bearing. If any problem is detected, stop and

inspect the machine. If necessary, remove and inspect the bearing.

Sound level and tone of a running bearing can be checked by a sound scope held in contact with the bearing housing. The sound is normal if a pure sound is heard. A high metallic sound or irregular sounds from the bearing, indicates an error of function. In such a case, the possible cause of the failure can be measured by using a vibrometer to quantitatively determine vibration amplitude and frequency.

Generally, bearing temperature can be estimated from the housing surface temperature. However, if the bearing outer ring is accessible through oil holes, etc, the temperature can be more accurately measured.

Under normal conditions, bearing temperatures rise with rotation and then reach a stable operating temperature after a certain period of time. If the temperature does not level off and continues to rise, if there is a sudden temperature rise, or if the temperature is unusually high, the bearing must be inspected.

Table 11.1 shows the required check items.

Table 11.1

Hand operation	Variation in torque Over-torque Sticking Abnormal sound	Imperfect installation Under-clearance, great seal friction, etc. Indent and flaw on raceway surface Inclusion of dust and other foreign matter
Power operation	Abnormal noise and vibration Abnormal temperature	Inclusion of dust and other foreign matter, indent on raceway surface,over-clearance, inadequate lubrication Use of improper lubricant, incorrect installation, under-clearance

11.5 Bearing removal (dismounting)

Bearings are often removed as part of periodic inspection procedures or during the replacement of other parts. In this case, these bearings must be handled with the same care as when it was installed. Bearings, shafts, housings and other related parts must be designed to prevent damage during the dismounting procedure and the proper dismounting tools must be employed.

Regarding the dismounting method, generally the press method (**Fig. 11.5**) and the puller method (Fig.11.6) are used to dismount the inner ring depending on bearing type and fitting conditions.

Be sure to apply the extraction force to the inner ring or outer ring only when removing the bearing. Never attempt to extract the bearing ring by applying force through the rolling elements.

11.6 Force needed for press-fitting and extraction

The force needed for press-fitting or extracting a particular inner ring onto or from a shaft can be determined by **formula (11.1)** below:

$$K_a = f_K f_E \frac{d}{d+3} \Delta d_F \cdots\cdots (11.1)$$

Where,

K_a : Force required for press-fitting or extraction N (kgf)

f_K : Resistance factor being determined by shaft to inner ring friction factor

For press-fitting········ 40 (4)

For extraction··········· 60 (6)

f_E : Coefficient depending on inner ring dimension

$$f_E = B\left[1 - \left(\frac{d}{F_1}\right)^2\right]$$

B : Inner ring width mm

d : Inner ring bore diameter mm

F_1 : Mean outer diameter of inner ring mm

Δd_F : Apparent interference μm

Actual press-fit force and extraction force could eventually exceed the respective calculate value due to installing error. Hence, it is recommended to design the dismounting tools so as to have the strength (rigidity) resistible to a load 5 times as much as the calculated press-fit force and pull-out force.

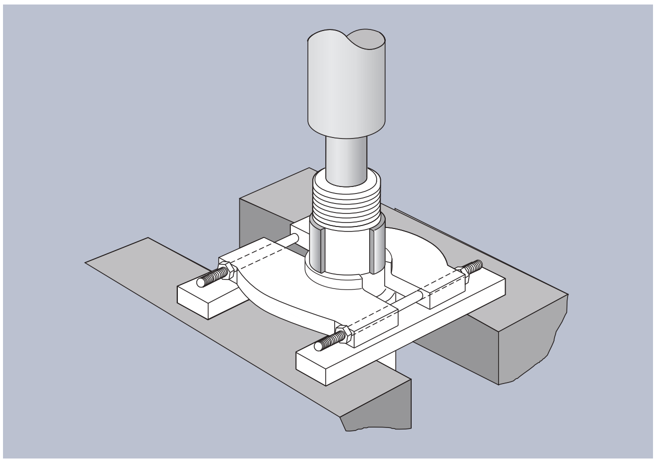

Fig. 11.5 Bearing removal by a press machine

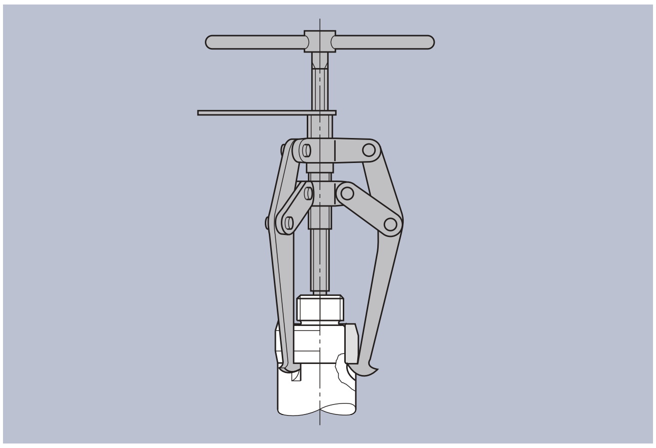

Fig. 11.6 Bearing removal by a puller

12. New Products Information

12. 1 HL Bearing

Bearing flaking can be categorized into two types: that which originates from inside of the bearing (subsurface flaking), and that which originates from the surface of the bearing.

Subsurface flaking usually occurs in areas where lubrication is considered to be good. This problem is believed to occur only when there exists a high level of contact stress. Present day steel is sufficiently clean so that cleanliness is not a contributing factor.

On the other hand, surface flaking is believed to be caused in areas where lubrication is insufficient. It is widely known that this problem is related to the oil film parameter (i.e. the ratio of oil film thickness at the point of contact to the combined surface roughness of the two objects in contact) which was derived from the elastohydrodynamic lubrication theory (EHL theory).

To reduce surface flaking, the oil film parameter needs to be increased. To do this, bearing manufactures have been working on both improving lubricants and surface roughness of the bearing raceway.

The EHL theory is based on the major premise that surface roughness of the contact surfaces is uniform. However, there are cases where the surface roughness determined in accordance with the EHL theory does not agree with the actual measured surface roughness.

In recent years a new theory has emerged. It contends that oil film formation in the contact areas can be improved by changing the character and direction of the machined parts surface finish.

NTN developed the long life HL (High Lubrication) bearing, based on the Micro EHL Theory, to reduce the problem of surface flaking.

12.1.1 Basic concept of HL bearing

The basic concept behind the development of the HL bearing is expressed by **Fig. 12.1**. These diagram are based on a flow model of the lubricant inside the contact area, developed by H.S. Cheng and his associates.The hatched areas in the diagrams are the contact points (elastically deformed) while the dotted lines show the flow of the lubricant.

The flow resistance of the lubricant is greater in (B) than in (A). This means that the volume of lubricant in each contact area increases, and accordingly the thickness of the oil film on the rolling contact surface also increases.

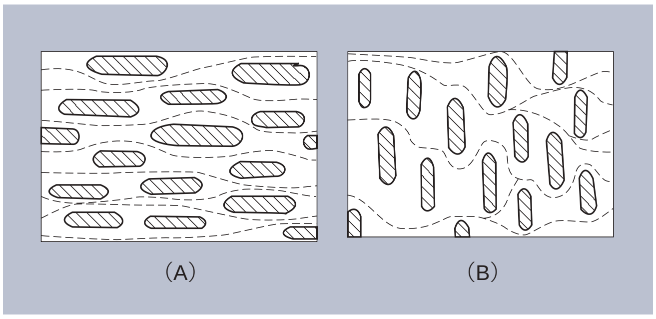

Fig. 12.1 Directional characteristics of finished surfaces and their effect on lubricant movement in a floe model

12.1.2 HL surface

As shown in **Fig. 12.2**, this newly developed surface (the HL surface : HL = High Lubrication) features a countless number of indentations (which are called micro oil pots) of about 10μm which are produced at random. The black areas in the figure are the micro oil pots. This surface , featuring the desired size and number of micro oil pots, can be produced by changing the grinding conditions. Depth of the micro oil pots is about 1μm.

12.1.3 HL bearing application examples

The HL surface-treated bearings are widely used in various fields. Such as car transmission, hydraulic devices, various reduction gears, etc.

HL surface treatment is applied to special applications, such as the rocker arm of a car engine where HL is on effective seizure preventive measure.

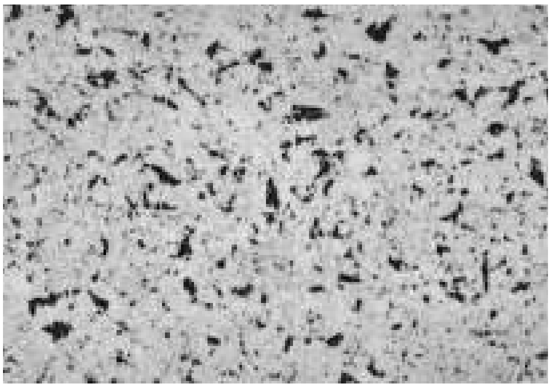

Fig. 12.2 Magnified photo showing HL roller surface

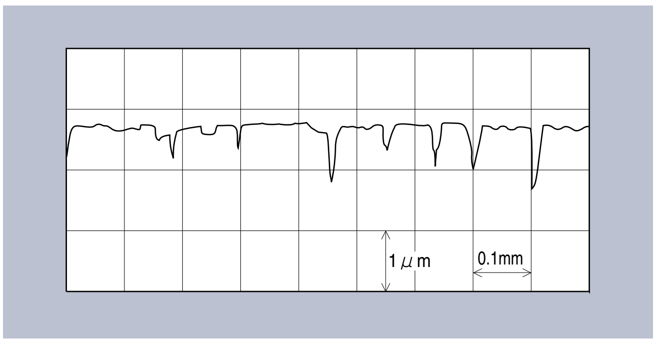

Fig. 12.3 HL surface roughness

12.2 Bearings with Solid Grease

"Solid grease" is a lubricant essentially composed of lubricating grease and ultra-high polymer polyethylene. Solid grease has the same viscosity as ordinary grease at normal temperature, but as a result of a special heat treatment process, this grease solidifies retaining a large proportion of the lubricant in it.

Thanks to this solidification, the grease does not easily leak from the bearing, even when the bearing is subjected to strong vibrations or centrifugal force, helping to extend bearing life.

All **NTN** needle roller bearings with Solid Grease are "full pack" products whose bearing space is nearly fully prefilled with solid grease.

12.2.1 Features of Bearings with Solid Grease

(1) Reduced lubricant leakage

Because the base oil is retained in a solid mixture, it is less likely to leak out of the bearing. During operation, temperature rise and/or centrifugal force will cause a gradual release of the base oil into the raceway groove. Eliminating grease leakage from the bearing ensures a consistent supply of lubricant and prevents contamination of the surrounding environment.

(2) Superior lubrication

Bearings with solid grease resist grease leakage prolonging bearing life in applications where high centrifugal force or vibration are present. The solid lubricant does not emulsify when exposed to water also extending both grease and bearing life.

(3) Sealing effect

Though solid grease protects a bearing against ingress of foreign matters (water, dust, etc.), it is not a sufficient means as a sealing device. Therefore, for applications that need reliable sealing performance, we recommend the use of contact type rubber seals.

12.2.2 Varieties of NTN Needle roller bearings with Solid Grease

The **NTN** needle roller bearings with Solid Grease can be categorized into the general purpose group and the high-speed group (**Table 12.1**).

12.2.3 Precautions for using NTN needle roller bearing with Solid Grease

(1) Each **NTN** needle roller bearing type has unique set of available dimensions. For detailed information, contact **NTN** Engineering.

(2) A minimum radial load is required to prevent skidding of the rolling elements when using full-pack solid grease. The minimum load required is approximately 1% of the bearing dynamic load rating.

(3) Do not use any **NTN** needle roller bearing with Solid Grease in a situation where it will come into contact with organic solvents (acetone, petroleum benzene, refined kerosene, etc.).

12.2.4 Typical applications of bearings with Solid Grease

- Bearing for the paper feeder of a printing machine
- Bearing for the mast roller guide of a forklift
- Support bearing for the swing arm of a motorcycle
- Bearing for a machine tool
- Guide bearing for the guide unit of a press machine
- Bearing for the link mechanism of an automatic loom
- Bearing for the conveyor guide of a food packaging machine

For detailed information about **NTN** bearings with Solid Grease, refer to **NTN** CAT. NO. 3022 (Bearings with Solid Grease).

Table 12.1 Varieties of NTN needle roller bearings with Solid Grease

Type	General purpose group (LP03)	High-speed group (LP08)
Major components	(Resin) Super high-molecular weight polyethylene (Lubricant) Li-mineral oil based grease	(Resin) Super high-molecular weight polyethylene (Lubricant) Urea-synthetic oil based grease
Permissible temperature range (Bearing outer ring)	-20 – 80˚C 60˚C max. for prolonged operation	-20 – 100˚C 80˚C max. for prolonged operation
	For installing the bearing to a shaft or housing, shrink fit technique may be adopted. However, be sure to limit the maximum heating temperature to 100˚C and maximum retention time to 2 hours. During this process, be careful not to turn the bearing.	
Limiting speed F_w: Roller set bore diameter (mm) n : Operating running speed (min^{-1})	$F_w \cdot n$ value$\leqq 3\times10^4$	$F_w \cdot n$ value$\leqq 6\times10^4$

13. Bearing Type Symbols and Auxiliary Symbols

Table 13.1 Bearing Type Symbols

Type code	Bearing type
811	Single-direction thrust cylindrical roller bearing, dimension series 11
812	Single-direction thrust cylindrical roller bearing, dimension series 12
893	Single-direction thrust cylindrical roller bearing, dimension series 93
874	Single-direction thrust cylindrical roller bearing, dimension series 74
A	Needle roller, spherical type
ARA821	Double-direction thrust cylindrical roller bearing
ARB821	Double-direction thrust cylindrical roller bearing
ARN	Needle roller bearing with double-direction thrust cylindrical roller bearing
AS11	Steel plate thrust washer, dimension series 11
AXA21	Double-direction thrust needle roller bearing
AXB21	Double-direction thrust needle roller bearing
AXK11	Needle roller and cage thrust assembly, dimension series 11
AXN	Needle roller bearing with double-direction thrust needle roller bearing
BF	Metallic flat cage for linear flat rollers
BK	Drawn cup needle roller bearing with close end
BR	Housing snap ring
CR	Cam follower, inch series
CRV	Full complement roller for cam follower,
DCL	inch series
	Drawn cup needle roller bearing with open end, inch series
F	Needle roller, plane type
FF	Linear flat roller
FR	Bottom roller bearing, for drawing frame
FRIS	Bottom roller bearing, for fine spinning frame and flyer frame
G	Synthetic rubber seal, one-lip type
GD	Synthetic rubber seal, double-lip type
GK	Needle rollers with split type cage
GS811	Housing washer, dimension series 11
GS812	Housing washer, dimension series 12
GS893	Housing washer, dimension series 93
GS874	Housing washer, dimension series 74
HCK	Drawn cup needle roller bearing for universal joint
HF	One-way clutch
HFL	One-way clutch integral with bearing
HK	Drawn cup needle roller bearing with open end
HMK	Drawn cup needle roller bearing with open end, for heavy load application
IR	Inner ring
JF‥S	Tension pulley holder
JPU‥S	Tension pulley and jockey pulley
K	Needle rollers with cage
K811	Cylindrical roller and cage thrust assembly, dimension series 11
K812	Cylindrical roller and cage thrust assembly, dimension series 12
K893	Cylindrical roller and cage thrust assembly, dimension series 93
K874	Cylindrical roller and cage thrust assembly, dimension series 74
KBK	Needle roller and cage assembly, for small end
KD	Linear ball bearing, stroking type
KH	Linear ball bearing, drawn cup type
KJ‥S	Needle roller and cage assembly
KLM	Linear ball bearing, machined ring type
KLM‥S	Linear ball bearing, clearance-adjustable type
KLM‥P	Linear ball bearing, open type
KMJ	Needle roller and cage assembly
KLJ‥S	Needle roller and cage assembly
KR	Cam follower
KRM	Miniature cam follower
KRMV	Miniature cam follower, full complement roller type
KRT	Cam follower, w/ tapped hole
KRU	Cam follower, shaft eccentric type
KRVT	Cam follower, full complement roller type, w/ tapped hole
KRV	Cam follower, full complement roller type
KRVU	Cam follower, full complement roller and shaft eccentric type
KV‥S	Needle roller and cage assembly
MI	Inner ring, inch series
MR	Machined ring needle roller bearing without inner ring, inch series
NA22	Roller follower with inner ring, dimension series 22
NA48	Machined ring needle roller bearing with inner ring, dimension series 48
NA49	Machined ring needle roller bearing with inner ring, dimension series 49
NA59	Machined ring needle roller bearing with inner ring, dimension series 59
NA69	Machined ring needle roller bearing with inner ring, dimension series 69
NA49…S	Clearance-adjustable needle roller bearing with inner ring
NAB2	Separable roller follower, w/ inner ring, diameter series2
NACV	Roller follower, full complement roller type, inch series
NAO	Machined ring needle roller bearing, separable type, with inner ring
NATR	Roller follower
NATV	Roller follower, full complement roller type
NIP	Grease nipple
NK	Machined ring needle roller bearing without inner ring
NKIA59	Complex bearing : Needle roller bearing with angular ball bearing dimension series 59
NKIB59	Complex bearing : Needle roller bearing with three-point contact type ball bearing dimension series 59
NKS	Machined ring needle roller bearing, w/o inner ring
NKX	Complex bearing : needle roller bearing with thrust ball bearing without dust-proof cover
NKX…Z	Complex bearing: Needle roller bearing with thrust ball bearing with dust-proof cover
NKXR	Complex bearing: Needle roller bearing with thrust cylindrical roller bearing without dust-proof cover
NKXR…Z	Complex bearing: Needle roller bearing with thrust cylindrical roller bearing with dust-proof cover
NUKR	Cam follower, full complement roller type
NUKRT	Cam follower, full complement roller type, w/ tapped hole
NUKRU	Cam follower, full complement roller type, w/ tapped hole, eccentric stud
NUTR2	Roller follower, diameter series 2
NUTR3	Roller follower, diameter series 3
NUTW	Roller follower, outer ring with center rib
PCJ	Needle roller and cage assembly, inch series
PK	Needle roller and cage assembly, for large end
PNA…R	Self-aligning needle roller bearing with inner ring
RF	Polyamide resin cage for linear flat rollers
RLM	Linear roller bearing
RNA22	Roller follower without inner ring, dimension series 22
RNA48	Machined ring needle roller bearing without inner ring, dimension series 48
RNA49	Machined ring needle roller bearing without inner ring, dimension series 49
RNA59	Machined ring needle roller bearing without inner ring, dimension series 59
RNA69	Machined ring needle roller bearing without inner ring, dimension series 69
RNA49…S	Clearance-adjustable needle roller bearing, without inner ring
RNAB2	Separable roller follower, w/o inner ring, diameter series 2
RNAO	Machined ring needle roller bearing, separable type, without inner ring
RPNA…R	Self-aligning needle roller bearing, w/o inner ring
WR	Snap ring for shaft
WS811	Thrust inner ring, dimension series 11
WS812	Thrust inner ring, dimension series 12
WS893	Thrust inner ring, dimension series 93
WS874	Thrust inner ring, dimension series 74
ZS	Thrust central ring

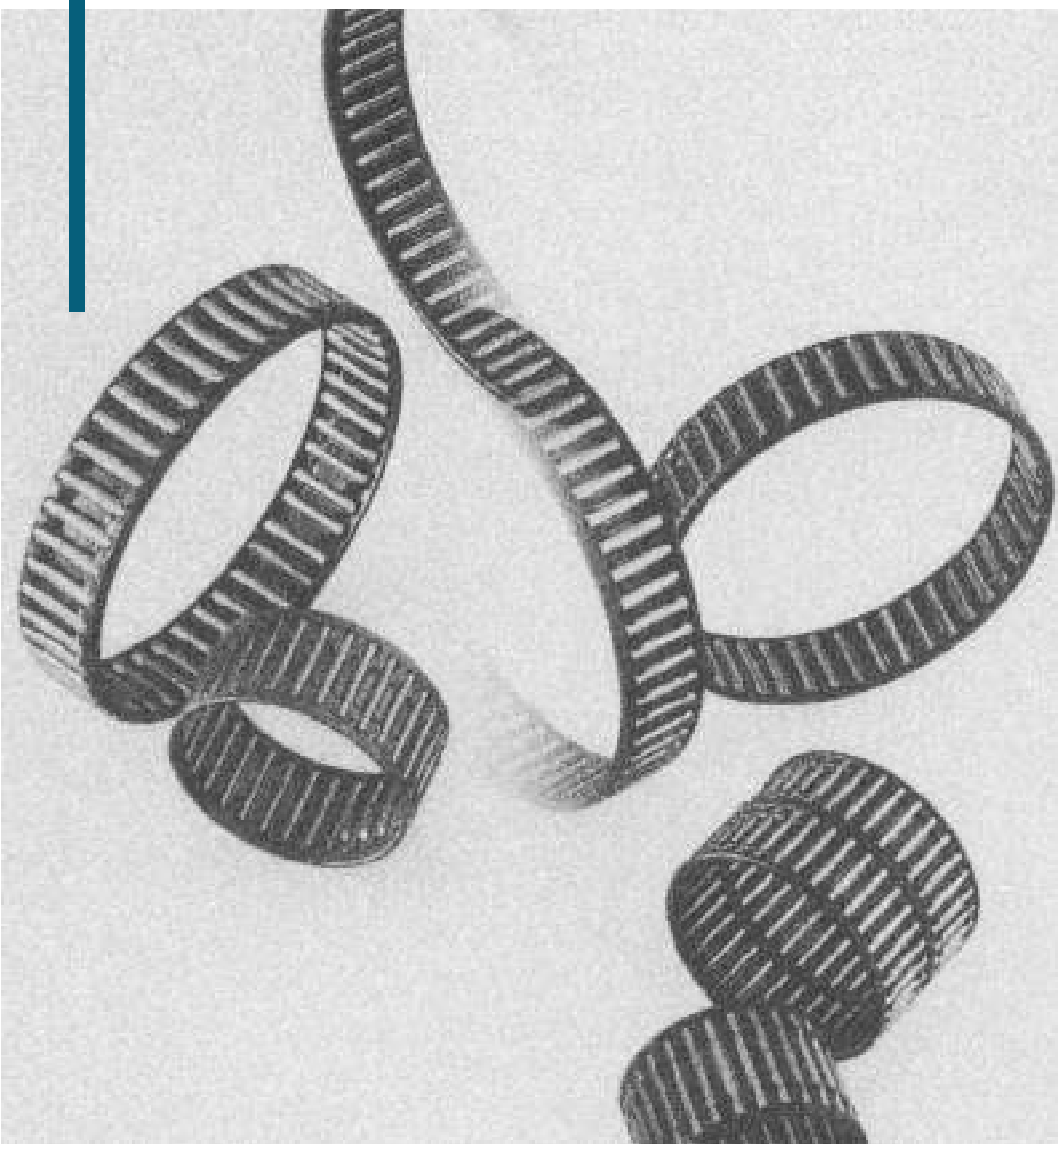
Table 13.2 Auxiliary symbols

	Symbol		Symbol representation
Initial symbols	Material heat-treatment symbols	TS-	Bearing for high temperature application which was heat-treated for dimensional stabilization
		E-	Bearing made of case-hardened steel
		8Q-	Nitro-carburized cage
		F-	Bearing made of stainless steel
		C-	Bearing made of carbon steel
	Expansion compensation	EC-	Expansion-compensated bearing
Basic symbols			
Suffix	Internal construction symbols	ZW	Double-row cage
		A,B,C	Internal construction change
	Cage symbols	J,JW	Steel plate punched cage
		L1	High strength brass cage
		T2	Polyamide resin cage
		S	Welded cage
	Seal symbol	L,LL	With synthetic rubber seal
	Bearing ring profile symbols	D	With oil hole
		D1	With oil hole and oil groove
		H	Cam follower with hexagon hole
	Roller symbol	T	Crowning and special heat treatment
	Combination symbols	D2,Dn	Complex bearing using two or more same bearings
	Clearance symbols	C2	Clearance smaller than ordinary clearance
		C3	Clearance larger than ordinary clearance
		C4	Radial clearance larger than C3
		NA	Non-interchangeable clearance
	Accuracy class symbols	P6	Bearing of JIS Class-6
		P5	Bearing of JIS Class-5
		P4	Bearing of JIS Class-4
	Lubrication symbols	/2AS	SHELL ALVANIA Grease 2
		/3AS	SHELL ALVANIA Grease 3
		/P03	Solid Grease
	Special symbols	V1~Vn	Special specification, requirements

Needle Roller Bearings

BEARING TABLES

Needle Roller and Cage Assemblies



Needle Roller and Cage Assemblies

This needle roller and cage assembly is one of the basic components for the needle roller bearing of a construction wherein the needle rollers are fitted with a cage so as not to separate from each other. The use of this roller and cage assembly enables to design a compact and lightweight construction by utilizing a shaft or a housing as the direct raceway surface, without using inner ring and outer ring.

The needle rollers are guided by the cage more precisely than the full complement roller type, hence enabling high speed running of bearing. In addition, its rigidity and load capacity are high for the specific space.

Type of needle roller and cage assembly	Cage type	Applicable shaft diameter (mm)	Composition of bearing number	Bearing number	Code items and respective dimensions
K (K··S) (K··T2) 	Machined ring type Polyamide resin type	φ3 – φ285	K 20 × 24 × 10 S Suffix Width Roller set outer diameter Roller set bore diameter Type code	K20×24×10S	Roller set bore diameter : φ20 Roller set outer diameter : φ24 Width : 10 S : Welded type
	Welded type	φ10 – φ100			
KMJ (KMJ··S) (PCJ) 	Punched type	φ15 – φ100	KMJ 20 × 26 × 13 Width Roller set outer diameter Roller set bore diameter Type code	KMJ20×26×13	Roller set bore diameter : φ20 Roller set outer diameter : φ26 Width : 13
	Welded type	φ10 – φ40			
KJ··S 	Welded type	φ20 – φ40	KJ 30 × 35 × 17 S Suffix Width Roller set outer diameter Roller set bore diameter Type code	KJ30×35×17S	Roller set bore diameter : φ30 Roller set outer diameter : φ35 Width : 17 S : Welded type
KV··S 	Welded type	φ7 – φ100	KV 30 × 35 × 17 S Suffix Width Roller set outer diameter Roller set bore diameter Type code	KV30×35×17S	Roller set bore diameter : φ30 Roller set outer diameter : φ35 Width : 17 S : Welded type
K··ZW 	Machined ring type	φ8 – φ285	K 20 × 24 × 45 ZW Suffix Width Roller set outer diameter Roller set bore diameter Type code	K20×24×45ZW	Roller set bore diameter : φ20 Roller set outer diameter : φ24 Width : 45 ZW : Double-row type
GK 	Machined ring type Split type	φ8 – φ285	GK 30 × 35 × 17 Width Roller set outer diameter Roller set bore diameter Type code	GK30×35×17	Roller set bore diameter : φ30 Roller set outer diameter : φ35 Width : 17

The ones with tail code T2 using polyamide resin cage shall be used at allowable temperature 120˚C and, under continuous running, at 100˚C or less.
The applied shaft diameter of welded type are described based on size that manufacturers can deal with a manufacturing. Therefore, it has nothing to do with the Demention Table.
Data for the GK type is not included in the dimension table. For detailed information, contact **NTN** Engineering.

Diameter variation of needle rollers

Diameter variation of needle rollers within one cage is less than 2um. The diameter tolerance groups for built-in needle rollers are identified by identification colors on the package label, as shown in **Table 1**.

The standard identification colors marked on each label are red, dark blue, blue, black and white, unless otherwise specially indicated.

In case of two or more bearings are mounted in tandem, those of same identification color must be used for equal distribution of bearing load.

Table 1 Color identification of diameter tolerances for needle rollers

Identification color on label	Diameter tolerance μm	Classification
Red	0〜−2	Standard
Dark blue	−1〜−3	
Blue	−2〜−4	
Black	−3〜−5	
White	−4〜−6	
Gray	−5〜−7	Semi-standard
Green	−6〜−8	
Brown	−7〜−9	
Yellow	−8〜−10	

Radial Clearance

When a shaft and a housing are used as the direct raceway surface, the radial clearance is determined by the shaft diameter and the housing hole dimension. Where the diameter tolerances for needle rollers are standard (tolerances color-identified in red, dark blue, blue, black, white), the shaft diameters and housing hole dimensions shown in **Table 2** are used.

Table 2 Recommended fits

Shaft diameter mm	Radial clearance					
	Smaller than ordinary clearance		Ordinary clearance		Larger than ordinary clearance	
	Shaft	Housing	Shaft	Housing	Shaft	Housing
〜80	j5	G6	h5	G6	g6	G6
80〜140	h5	G6	g5	G6	f6	G6
140〜	h5	G6	f5	H6	f6	G6

Shaft and housing specifications

Where a shaft and a housing are used as the direct raceway surface, the raceway surface must meet the specifications described in **Table 3**.

Table 3 Shaft and housing specifications (recommended)

Characteristics	Shaft	Housing
Roundness (max)	IT3	IT4
Cylindricality (max)	IT3	IT4
Surface roughness (max)	Refer to **Table 8.4** on page A-40.	
Surface hardness	HRC58〜64	
Depth of hardened layer (min)	Refer to formula **(8.1)** on page A-40.	

Bearing installation related dimensions

The tolerances for the nominal dimension "Bc" of cage specified in **Table 4** are recommended as the guide width b of cage.

Table 4 Guide width dimensions (recommended)

Unit : mm

Classification	Tolerances for guide width b	
	Single row	Double row
Metric system	$Bc\,^{+0.2}_{0}$	$Bc\,^{+0.3}_{+0.1}$
Inch system	$Bc\,^{+0.4}_{+0.2}$	$Bc\,^{+0.5}_{+0.3}$

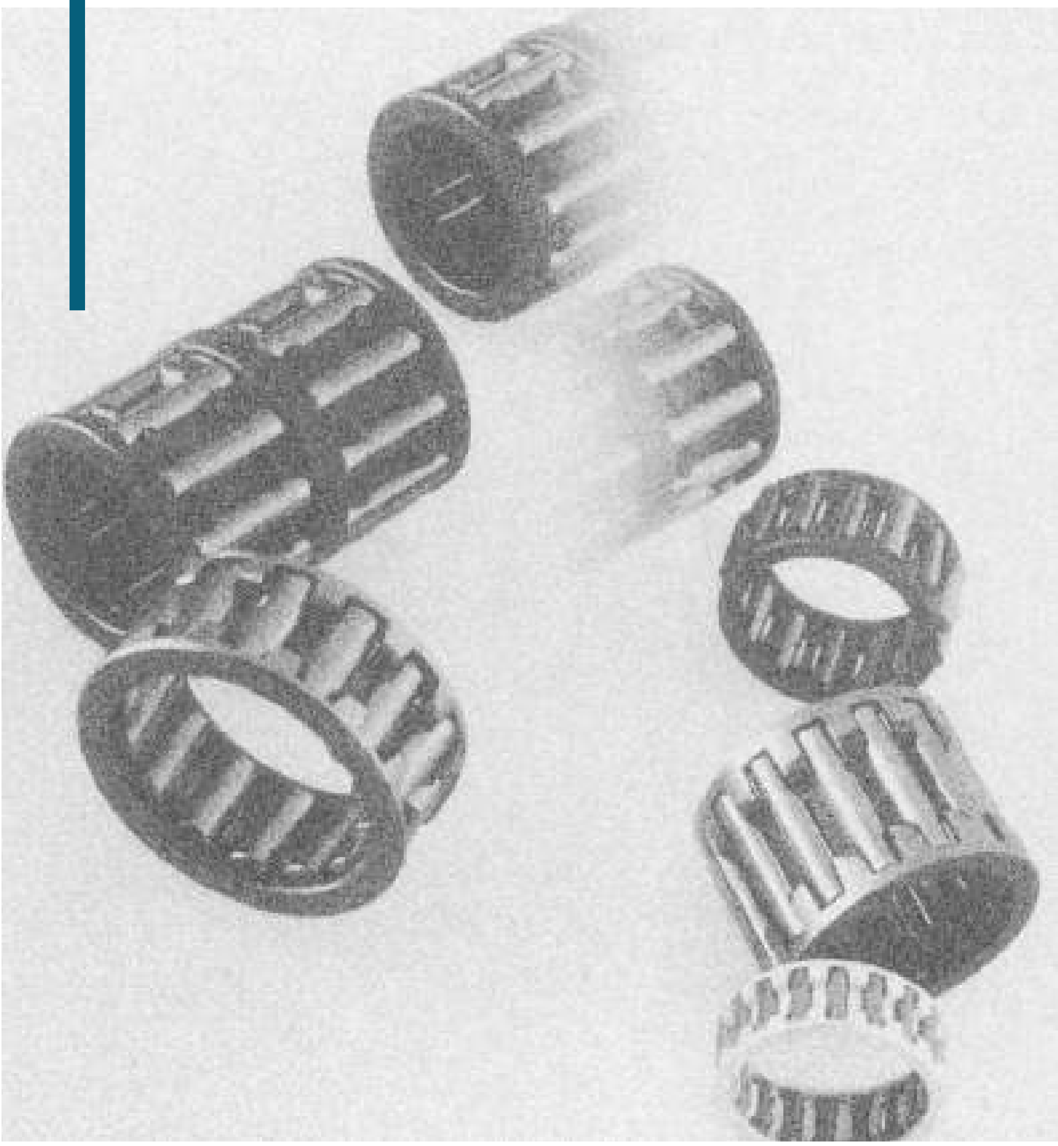
Needle Roller and Cage Assemblies for connecting rod bearings



Needle Roller and Cage Assemblies for connecting rod bearings

These needle roller and cage assemblies are specially designed so as to be adaptable to the operating environmental conditions for the connecting rods of small and medium reciprocal engines and compressors.

The connecting rods are used under a severe operating condition wherein acting load magnitude and direction fluctuate rapidly as well as under an high temperature and strict lubrication environment. Therefore, special measures are manly undertaken for the cage structure, material and machining method so that the needle roller and cage assemblies are resistible to the said operating condition and environment.

Type of needle roller and cage assembly	Location	Cage type	Applicable shaft diameter (mm)	Composition of bearing number
PK 	Large end side	Machined ring type	ϕ10 – ϕ38	PK 20×26×13.8 X1 Suffix Width Roller set outer diameter Roller set bore diameter Type code
GPK 		Machined type Split type	ϕ10 – ϕ38	GPK 20 × 26 × 13.8 X Suffix Width Roller set outer diameter Roller set bore diameter Type code
KMJ··S 		Welded type	ϕ10 – ϕ38	KMJ 10 × 14 × 8.8 S Suffix Width Roller set outer diameter Roller set bore diameter Type code
KBK 	Small end side	Machined ring type	ϕ7 – ϕ25	KBK 14 × 18 × 17 Width Roller set outer diameter Roller set bore diameter Type code
KV··S 		Welded type	ϕ7 – ϕ100	KV 8 × 11 × 8 S V4 Suffix Suffix Width Roller set outer diameter Roller set bore diameter Type code

Data for the GPK, KMJ··S, KV··S types are not included in the dimension table. For detailed information, contact NTN Engineering.

Bearing number	Code items and respective dimensions	Remarks
PK20×26×13.8X1	Roller set bore diameter : φ20 Roller set outer diamete r: φ26 Width : 13.8 X1 : numbered entry	Cage intended to guide outer ring, eventually surface- treated by non-ferrous plating, etc.
GPK20× 26 ×13.8X	Roller set bore diameter : φ20 Roller set outer diameter : φ26 Width :13.8 X : numbered entry	Cage intended to guide outer ring, eventually surface- treated by non-ferrous plating, etc. Can be applied to a crank of integral structure.
KMJ10×14×8.8S	Roller set bore diameter : φ10 Roller set outer diameter : φ14 Width :8.8 S : welded type	Cage intended to guide outer ring, eventually surface- treated by non-ferrous plating, etc.
KBK14×18×17	Roller set bore diameter : φ14 Roller set outer diameter : φ18 Width : 17	Type KBK is intended to guide inner ring, which of the guide surface is designed as long as possible to thereby reduce the surface pressure. In addition, the roller length is so designed as to be maximum against the width of connecting rod, for high load capacity. On the other hand, Type V••S intended for outer ring guide needs a guide along the bore surface of connecting rod.
KV8×11×8SV4	Roller set bore diameter : φ8 Roller set outer diameter : φ11 Width : 8 S : welded type V4 : Special specification	

Radial clearance

Table 1 shows the recommended clearance values though the radial clearance differs depending on bearing clearance, load, revolutions and ambient temperature.

The proper radial clearance can be got by proper selection and combination of roller diameter, connecting rod hole diameter and pin diameter. **Table 2** shows the examples of selection and combination of those.

Table 1 Recommended clearance values

Unit : μm

Pin diameter mm Over	incl.	Large end side	Small end side

Connecting rod and pin specifications

Connecting rod (bore surface), crank pin and piston pin (outer surface) can be used as direct raceway surface. However, these surfaces must be resistible to great load while maintaining high accuracy. For that, connecting rods and pins acting as the direct raceway surface must comply with the specifications specified hereunder.

Any connecting rods shall be made of cement steel, e.g. chrome molybdenum steel (SCM415, etc.), nickel chrome molybdenum steel (SNCM420, etc.) and any crank pins and piston pins shall also be made of cement steel, e.g. chrome steel (SCr420, etc.), all of which shall be surface-hardened by carburizing.

The surface hardness of each shall range from HRC58 to 64 and adequate depth of effective carburizing-hardened layer shall be secured up to Hv550. The depth of effective carburizing-hardened layer differs depending on actual load and pin diameter.

Feel free to contact **NTN** for the more detailed information.

The respective profile accuracy of connecting rod hole, crank and piston pin outer surfaces shall be as specified in **Table 3**.

Furthermore, the parallelism of crank pin and piston pin shall be 0.02mm or less against 100mm. (**Fig. 1**)

The surface roughness shall be 0.2a for connecting rod and 0.1a for pin outer surface as a guideline.

Table 3 Recommended accuracy of connecting rod and pin

Unit : μm

Parts	Characteristics	Pin diameter classification mm ～14	14～18	18～25	25～30	30～40
Connecting rod	Roundness (max)	3	4	4	5	5
	Cylindricality (max)	2	3	3	4	4
Pin	Roundness (max)	2	2	3	3	4
	Cylindricality (max)	1	1	2	2	3

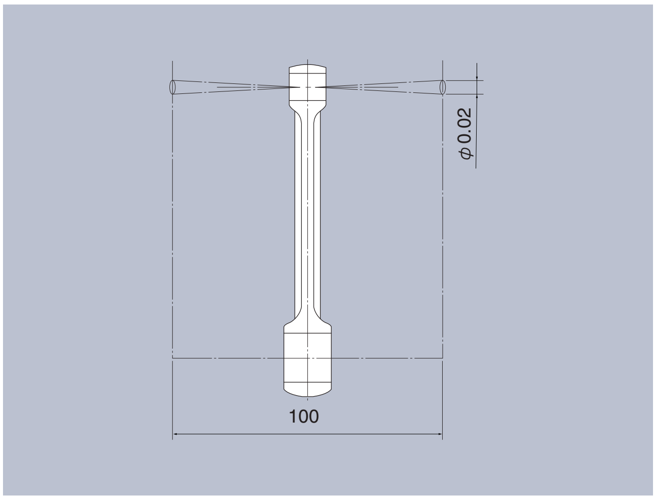

Fig. 1

Regulation to connecting rod

Two methods are available as follows to regulate axial motion of a connecting rod; one method is to make smaller a clearance between the rod and crank web at large end side (Method of regulating at large end side) and another method is to narrow a clearance between the rod and piston boss at the small end side (Method of regulating at small end side).

In general, the method of regulation at large end side is mostly adopted to get accurate motion of a connecting rod.

On the other hand, the method of regulation at small end side is adopted when regulation at large end side disables to secure good lubrication to the bearing and the guide surface at large end side due to short connecting rod and comparatively high revolutions.

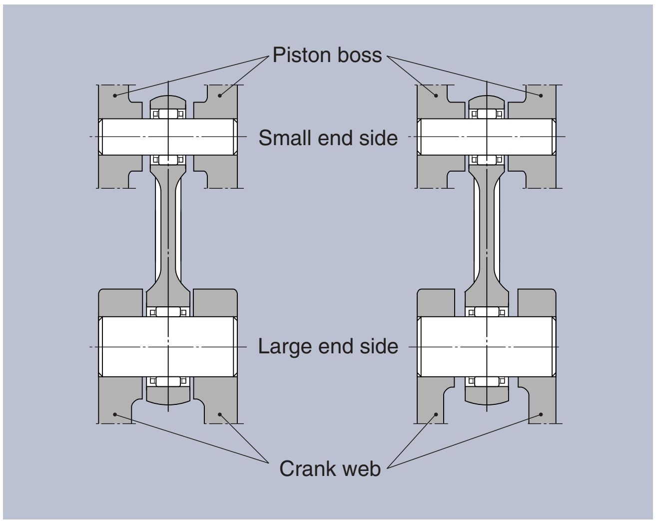

Fig. 2. Regulation at large end side Fig. 3 Regulation at small end side

Regulation at large end side

This method regulates axial motion of a connecting rod by forming a sliding surface between the large end of the connecting rod and the side face of crank web. For the use of this method, however, the connecting rod must be provided, on its bore surface, with oil hole, slot and oil groove to feed lubrication oil in and onto the bearing and guide surface at large end side.

The crank web end face shall be surface-hardened as necessary or otherwise a side washer of copper alloy or hardened steel shall be fitted on the guide surface.

On the other hand, the needle roller and cage assembly at small end side shall be guided in axial direction by the side face of piston boss. A great play shall be secured between the piston boss and the connecting rod.

Regulation at small end side

This method regulates axial motion at the small end face of a connecting rod and the side face of a piston rod. Generally a connecting rod is not provided with oil groove and slot to lubricate the guide surface at small end side, but on occasion it is surface-hardened and uses a side washer.

Usually a connecting rod shall be provided with a through-hole (at its small end side) to lubricate the bearing unit.

On the other hand, at the large end side a free clearance exists between the connecting rod and the crank web and, therefore, generally special measures such as oil groove to lubricate, etc.

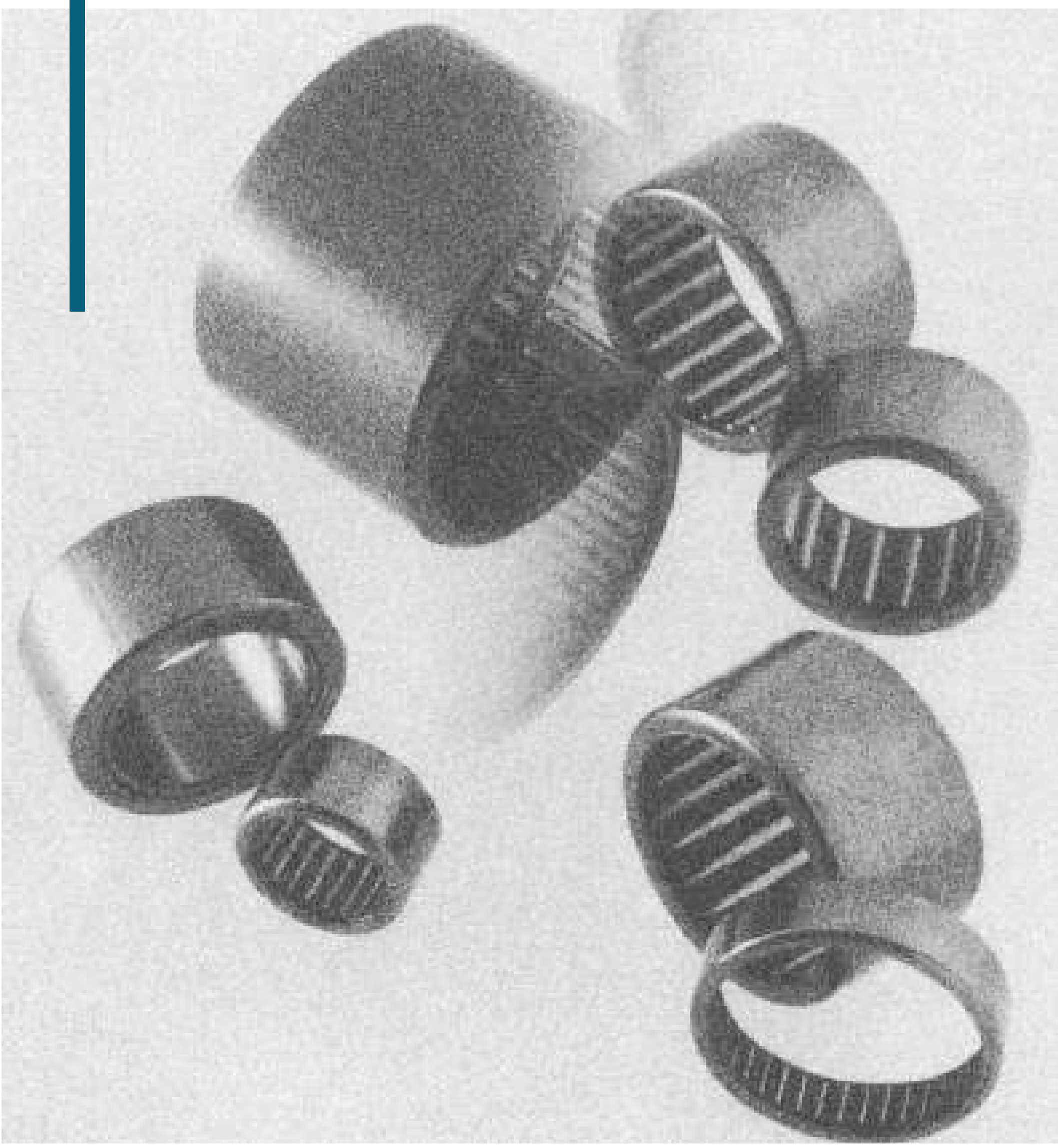
Drawn Cup Needle Roller Bearings



Drawn Cup Needle Roller Bearings

This bearing type is composed of an outer ring drawn from a thin steel plate by precision drawing, needle rollers and a cage assembled in the outer ring after the raceway surface thereof was hardened (A bearing marked with a suffix including “M” is subjected to heat-treatment after assembly.). Of the bearings with outer ring, this bearing type is a bearing with the smallest section height which enables space-saving and cost-saving.

Usually design is so made as to use a shaft as th direct raceway surface without using inner ring. The outer ring of this bearing type is of such a constructi that the needle rollers and the cage are not separated from one another, so that the bearing is only press-fitt in a rigid housing with proper fit torque. Thus, this bearing type needs no snap ring, etc. to fix itself in direction and, in addition, is easy to handle.

Type of bearing			Applicable shaft diameter (mm)	Composition of bearing number	Bearing number	Code items and dimensions	Remarks
HK (HK··T2) 	Standard series	Open end	φ3 – φ50	HK 06 09 T2 T2: Suffix 09: Width 06: Roller set bore diameter HK: Type code [Suffix] T2 : Resin cage C : Welding cage	HK0609T2	Roller set bore diameter : φ6 Width : 9 T2 : Resin cage	The bearings with suffix T2 using polyamide resin cage shall be used at allowable temperature 120˚C and, under continuous running, at 100˚C and less. A bearing marked with a suffix including “F” is a Premium Shell bearing. For detailed information about Premium Shell bearings, refer to **NTN** CAT. NO. 3029 (Premium Shell Bearings). A bearing marked with a suffix including “M” is a drawn cup bearing that is heat-treated after assembly (“pre-bent” specification).
HK··L 	Standard series	Open end single side seal	φ12 – φ50	HK 20 18 L / 3AS 3AS: Suffix L: Suffix 18: Width 20: Roller set bore diameter HK: Type code	HK2018L/3AS	Roller set bore diameter : φ20 Width : 18 L : single side seal 3AS : grease	This seal type (Tail code : L or LL) synthetic rubber seal built in at its single side or double sides is internally filled with lithium soap base grease. To avoid deterioration of seal and grease, use a bearing in a temperature range of -20 to 120˚C. For continuous machine operation, limit the maximum permissible operating temperature to 100˚C. The roller length and rated load of this bearing type are shorter and smaller than those of the open type of same dimension.
HK··LL 	Standard series	Open end double-side seal	φ12 – φ50	HK 20 20 LL / 3AS 3AS: Suffix LL: Suffix 20: Width 20: Roller set bore diameter HK: Type code	HK2020LL/3AS	Roller set bore diameter : φ20 Width : 20 LL: Double-side seal 3AS : grease	
HK··ZWD 	Standard series	Open end double-row type	φ15 – φ30	HK 20 30 ZW D D: Suffix ZW: Suffix 30: Width 20: Roller set bore diameter HK: Type code	HK2030ZWD	Roller set bore diameter : φ20 Width : 30 ZW : Double-row cage D : Outer ring with oil hole	This type is provided with oil hole on its outer ring.

The lower limit of safety factor S_0 for NTN drawn cup needle roller bearings shall be 3. The lower limit for NTN Premium Shell bearings shall be 2.

Bearing Fits

It is common that drawn cup needle bearing is press-fitted in a housing by shrinkage fit so post press-fit inscribed circle diameter (F_w) comes to ISO Tolerance Rang Class F8. The post press-fit inscribed circle diameter (F_w) depends on the housing material and rigidity. It is therefore desirable to decide the interference based on the data measured in pre-testing.

Where the housing rigidity is adequately high, the post press-fit inscribed circle diameter (F_w) is secured in nearly F8 range and nearly ordinary radial clearance can be got by adopting the data of bearing fit in housing and on shaft as shown in **Table-1**.

Table 1 Bearing fit in housing and on shaft (recommended)

Bearing type	Housing		Shaft	
	Iron series	Light alloy	Without inner ring	With inner ring
HK,BK	N6 (N7)	R6 (R7)	h5 (h6)	k5 (j6)
HMK,DCL	J6 (J7)	M6 (M7)		
HCK	F7	—	k6	—

Accuracy of housing and shaft

Since the outer ring of drawn cup needle roller bearing is thin-walled, the bearing performance is significantly affected by the dimensional accuracy, profile accuracy and bore surface roughness of the housing into which the bearing is press-fitted. Therefore, the housing bore should satisfy the accuracy levels summarized in **Table 2**. For accuracy of a shaft that uses an inner ring, refer to **Table 8.3** in Sec. **8.3 "Accuracy of shaft and housing"** (page A-40); for accuracy of a shaft that is directly used as a raceway surface, refer to **Table 8.4** in Sec. **8.4 "Accuracy of raceway surface"** (page A-40).

Table 2 Accuracy of housing bore (recommended)

Property	Tolerance
Roundness (Max)	IT4 or less
Cylindricity (Max)	IT4 or less
Surface roughness (Max)	1.6a

Oil hole dimension in outer ring

The outer rings of double-row (Tail code : ZW) needle roller and cage assembly Type HK and Type BK are provided with an oil hole to facilitate oil lubrication to the bearing. **Table 3** shows the nominal oil hole diameter.

Table 3 Diameter of oil hole in outer ring (Metric system)

Unit : mm

Outer ring diameter over	Outer ring diameter incl.	Nominal oil hole diameter
5	10	1.5
10	20	2.0
20	40	2.5
40	80	3.0
80	200	3.5

Bearing installation

When installing a drawn cup needle roller bearing to a housing, place the jig on the marking side of the bearing, and then press-fit the bearing into the correct location in the housing bore. (A "pre-bent" bearing marked with a suffix including "M" has no directivity for installation.) **Further, hammering directly the bearing ring in installing (press-fitting) is not allowed absolutely.** In installing, it is recommended to use a mandrel with O-ring as illustrated in **Fig. 1** as a press-fitting jig. The use of this mandrel would enable to insert easily any drawn cup needle bearing in a housing without risk of twisting and fall-down.

Drawn cup needle roller bearing needs no a snap ring and a shoulder for positioning itself in a housing, **but the bearing must be press-fitted so carefully as not to allow its side face to strike the shoulder for preventing it from deforming, where press-fitted in a housing with shoulder.**

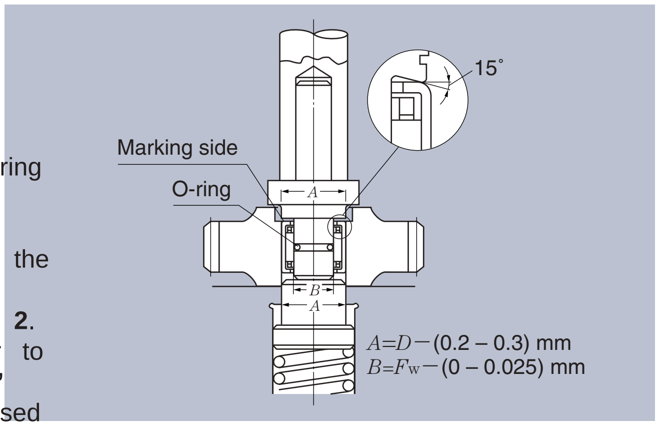

Fig. 1

The Type HCK for application to universal joints is fixed to the joint yoke by caulking, using a special-purposed assembler. Feel free to contact NTN for any inquiry about the special-purposed assembler (IPH Machine).

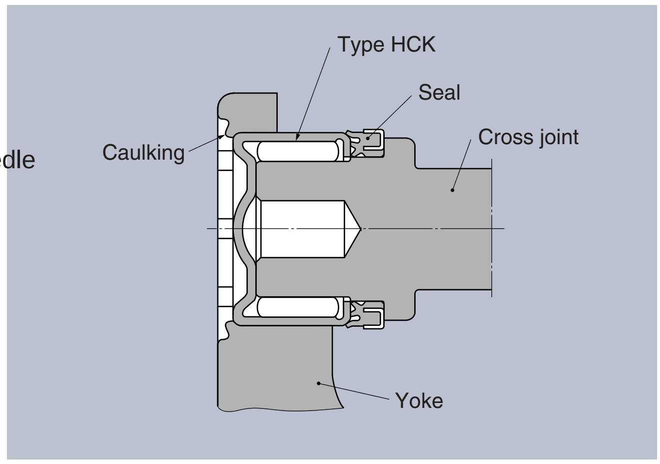

Fig. 2

Bearing Tolerances and Measuring Methods

The outer ring of drawn cup needle roller bearing is so thin-walled that deformation thereof to a certain extent is unavoidable in the manufacturing processes, particularly in the heat-treating process. However, the outer ring is so designed that it is reformed normally from such deformation when being press-fitted in a housing with specific dimensional accuracy and, as a result, it can have the accuracy required to fulfill its specific function.

Hence, **it is meaningless to measure the dimensional accuracy of bearing itself before being press-fitted. So, the following measuring method is used; a bearing to be measured is press-fitted in a linkage of specific dimension (20mm or more in wall thickness) and thereafter the inscribed circle diameter (F_w) is measured using a plug gauge or a taper gauge to evaluate the bearing accuracy.**

Tables 4 to **7** show the dimensional tolerances for the bore diameter of each ring gauge and the roller set b diameter (F_w) each of standard metric series drawn cup needle roller bearings Type HK and BK, heavy load series Type HMK (metric series), inch series Type DCL and inch series HCK for application to universal joints.

When measuring the roller set bore diameter (F_w) of a drawn cup needle roller bearing, the GO side dimensio shall be the lower limit of dimensional tolerance of the roller set bore diameter; and the NOT GO side dimens shall be a sum of the upper limit of dimensional toler of the roller set bore diameter and 2μm.

When measuring the roller set bore diameter of a drawn cup needle roller bearing, do not repeat insertion/removal with the ring gage. Also, do not install a bearing, which has been press-fitted into the ring gage for inspection, to an actual machine product.

Calculation Examples

Shrinkage factor and post-installation clearance of drawn cup needle roller bearing

The recommended fit data for the standard bearings is as described in **Table 1** on page B-35. This paragraph describes hereunder the calculation methods to be used when the bearing fit conditions are reviewed in detail.

1) Calculation of bearing shrinkage factor

For the drawn cup bearings, the shrinkage factor is calculated using the following method.

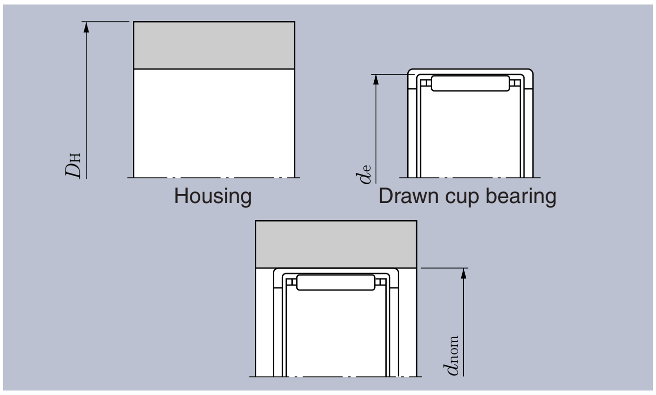

Fig. 3

$$\lambda = \frac{2t}{E_2} \cdot \frac{1-S^2}{\dfrac{(0.7S^2+1.3)(1-t^2)}{E_1} + \dfrac{(0.7+1.3t^2)(1-S^2)}{E_2}} \quad \cdots\cdots \quad \textbf{(1)}$$

Where,

λ : Outer ring shrinkage factor
D_H : Housing outer diameter mm
d_{nom} : Nominal diameter of fitting portion mm
d_e : Rolling surface diameter of outer ring mm
E_1 : Modulus of housing vertical elasticity (Young's modulus) MPa (kgf/mm²)
E_2 : Modulus of outer ring vertical elasticity (Young's modulus) 2.07×10^6MPa (21 200kgf/mm²)

$$S = \frac{d_{nom}}{D_H}$$

$$t = \frac{d_e}{d_{nom}}$$

2) Inscribed circle diameter after complete bearing fit in the housing on actual machine

[1] Inscribed circle diameter in press-fitting of master ring

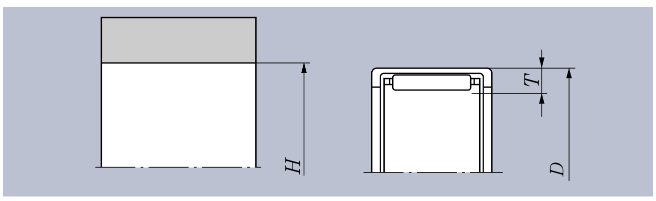

Fig. 4

H : Housing inner diameter mm
T : Roller diameter + plate thickness mm
D : Outer diameter of drawn cup needle roller bearing mm
L_i : Post press-fit inscribed circle diameter mm

When the master ring is press-fitted, the dimension of "roller diameter + plate thickness" remains unchanged. Hence, the inscribed circle diameter L_i is determined by the following **formula**.

$$L_i = D - 2T - \lambda (D - H) = (1-\lambda)D - 2T + \lambda H \cdots\cdots\cdots \textbf{(2)}$$

Determine the mean value of "roller diameter + plate thickness" (2T) and standard deviation from **formula (2)**. The mean value of **formula (2)** is determined as follows.

$$m_{Li} = (1-\lambda)\, m_D - m_{2T} + \lambda\, m_H \cdots\cdots\cdots\cdots\cdots\cdots \textbf{(3)}$$

Standard deviation of formula **(2)**

$$\sigma_{Li}{}^2 = (1-\lambda)^2 \cdot \sigma_D{}^2 + \sigma_{2T}{}^2 + \lambda^2 \sigma_H{}^2 \cdots\cdots\cdots\cdots \textbf{(4)}$$

In the case of master ring, $\sigma_H = 0$ due to the **formula (4)** is expressed as follows.

$$\sigma_{Li}{}^2 = (1-\lambda)^2 \cdot \sigma_D{}^2 + \sigma_{2T}{}^2 \cdots\cdots\cdots\cdots\cdots\cdots\cdots \textbf{(5)}$$

The unknown values in **formulas (3)**, **(5)** are only m_{2T} and $\sigma_{2T}{}^2$. Hence, substitute the known numerical values for **formulas (3) (5)** to determine m_{2T} and $\sigma_{2T}{}^2$.

[2] Even when bearing ring is press-fitted in the housing on actual machine, consider the inscribed circle diameter similarly to the master ring press-fit. Herein, the calculation formulas for press-fit in the housing on actual machine can be discriminated as follows from **formula (3)**, **(4)** by adding " ' " to each formula.

$$m_{Li}' = (1-\lambda')\, m_D - m_{2T} + \lambda'\, m_H' \cdots\cdots\cdots\cdots\cdots \textbf{(6)}$$

$$\sigma_{Li}'^2 = (1-\lambda')^2 \cdot \sigma_D{}^2 + \sigma_{2T}{}^2 + \lambda'^2 \sigma_H'^2 \cdots\cdots\cdots \textbf{(7)}$$

[3] For m_{2T} and $\sigma_{2T}{}^2$ in **formula (6)**, **(7)**, substitute the values determined previously for the respective formula.

[4] From the calculations, the inscribed circle diameter in press-fitting in the housing on actual machine can be expressed in the following **formula**

$$L_i' = m_{Li}' \pm 3\sigma_{Li}' \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots \textbf{(8)}$$

[5] Radial internal clearance can be determined considering the mean value and standard deviation of shaft in **formulas (6)**, **(7)**.

[6] The aiming radial internal clearance value is generally set up so an ordinary clearance can be got. However, the recommended clearance values are available every the individual portions in the case of bearing application to automobile. Feel free to contact **NTN** for the detail.

Suffix (Vn) is different from the Dimple type and the Waffle type. For more informations, contact NTN engineering

Machined Ring Needle Roller Bearings

Machined Ring Needle Roller Bearings

The machined ring of this bearing type contains needle rollers and a cage. The outer ring and the needle rollers are inseparable from each other by means of double-side ribs on the outer ring or side plates.

Because of its machined (solid) outer ring enabling to make it more rigid and upgrade the bearing accuracy, this bearing type is suitable for an application requiring high speed, high load and high running accuracy. These machined ring needle roller bearings are available in two types -- one without inner ring and another with inner ring -- considering the case of using a shaft as the direct raceway surface without using inner ring.

Bearing type	Applicable shaft diameter (mm)	Composition of bearing number	Remarks
Type RNA49 	ϕ7 – ϕ12	**RNA 49 5 T2** Suffix (T2) Bore dia. No. (5) Dimension series (49) Type code (RNA) **[Suffix]** T2: Resin cage	The bearings with suffix T2 using polyamide resin cage shall be used at allowable temperature 120˚C and, under continuous running, at 100˚C and less. The dimension series is in compliance with JIS B 1512 or ISO 15.
Type NA49 	ϕ5 – ϕ9

Bearing Tolerances

The dimensional accuracy, profile accuracy and running accuracy of machined ring needle roller bearings are specified in JIS B 1514 (Accuracy of Rolling Bearings). (Refer to Section 4 "**Bearing Tolerances**", **Table 4.3** on page A-26.) Although the accuracy of **NTN** standard bearings conforms to JIS Class-0, **NTN** can also supply bearings conforming to JIS Class-6, -5 and -4.

The dimensional tolerances for the roller set bore diameter (F_w) of **Types NK**, **RNA**, **NKS**, and **MR** each lacking an inner ring fall in the ISO tolerance class F6.

Feel free to contact **NTN** for the further detail of these bearings.

For applications that need particularly high running accuracy, certain bearing users install the inner ring onto the shaft and then grind the raceway surface to targeted accuracy. To fulfill this type of request, **NTN** will supply a special inner ring whose raceway surface includes a grinding allowance. For details, contact **NTN** Engineering.

Radial internal clearance and bearing fits

NTN machined ring needle roller bearings (with inner ring) are manufactured to the tolerance range of radial internal clearance in **Table 5.1** in Sec. **5.1 "Bearing radial internal clearance"** (page A-30). Because of the narrow non-interchangeable clearance range, the bearings shipped after adjusted to a specific non-interchangeable clearance must be installed with the clearance remained unchanged.

The dimensional tolerances (fits) of a shaft and housing bore to which the bearing with inner ring is installed should be in accordance with type and magnitude of load, and dimensions of the shaft and housing bore. For information about the dimensional tolerances of a shaft and housing bore, refer to Sec. **6.4 "Recommended internal fits"** (page A-33). For the profile accuracy and surface roughness of the shaft and housing bore corresponding to the recommended internal fits, **Table 8.3** in Sec. **8.3 "Shaft and housing accuracy"** (page A-40).

A bearing not having an inner ring directly uses the shaft as raceway surface, and the dimensional tolerances of the shaft diameter (raceway diameter) can vary depending on the operating internal clearance of the bearing as summarized in **Table 1** below. For this type of bearing usage, the dimensional tolerance class for the housing bore is K7, which is most commonly adopted tolerance class. When wishing to adopt a dimensional tolerance class other than K7 for the housing bore, contact **NTN** Engineering for technical assistance.

For the profile accuracy, surface roughness and surface hardness of the shaft that functions as raceway surface, refer to Sec. **8.4 "Raceway surface accuracy"** (page A-40) and Sec. **8.5 "Material and hardness of raceway"** (page A-40).

Oil hole dimension of the outer ring

The outer ring is provided with an oil hole and an oil groove to facilitate oil lubrication to bearing. (However, the description above does not apply to the **Type NK** bearings whose roller set bore diameter (F_w) measures 12 mm or less and the **Type NKS** bearing whose roller set bore diameter (F_w) measures 110 mm or less.)

Table 2 shows the oil hole dimension every outer ring diameter.

Table 2 Oil hole dimension

Outer ring outer diameter Over	incl.	Oil hole dia. (mm)	Number of oil hole
—	20	2.0	1
20	40	2.5	1
40	80	3.0	1
80	200	3.5	1
200	350	4.0	1
350	—	5.0	1

Mounting relations

In the case of raceway with an oil hole, **the bearing must be installed so that the oil hole can locate on the non-load area.** In addition, any bearing with inner ring **must be used within the allowable stroking value (s) (with the rollers retained within the effective contact length range of inner ring).**

For the allowable stroking value (s), refer to **Fig. 1** and applicable "Dimensions Table".

The inner ring and outer ring of machined ring needle roller bearing must be positioned in axial direction by shoulder or snap ring in this case. The mounting relation dimensions about the shaft and housing bore for this case are found in the relevant dimension table.

Note 1) Allowable minimum chamfer dimension r. 2) Allowable axial stroking value of inner ring against outer ring.
3) Max. allowable dimension of radius r_a for corner roundness on shaft/housing.
Remarks: Nominal code number of inner ring (**IR**) comprises the codes of **IR** bore diameter×outer diameter×width.

Note 1) Allowable minimum chamfer dimension r. 2) Allowable axial stroking value of inner ring against outer ring.
3) Max. allowable dimension of radius r_a for corner roundness on shaft/housing.
Remarks: Nominal code number of inner ring (**IR**) comprises the codes of **IR** bore diameter×outer diameter×width.

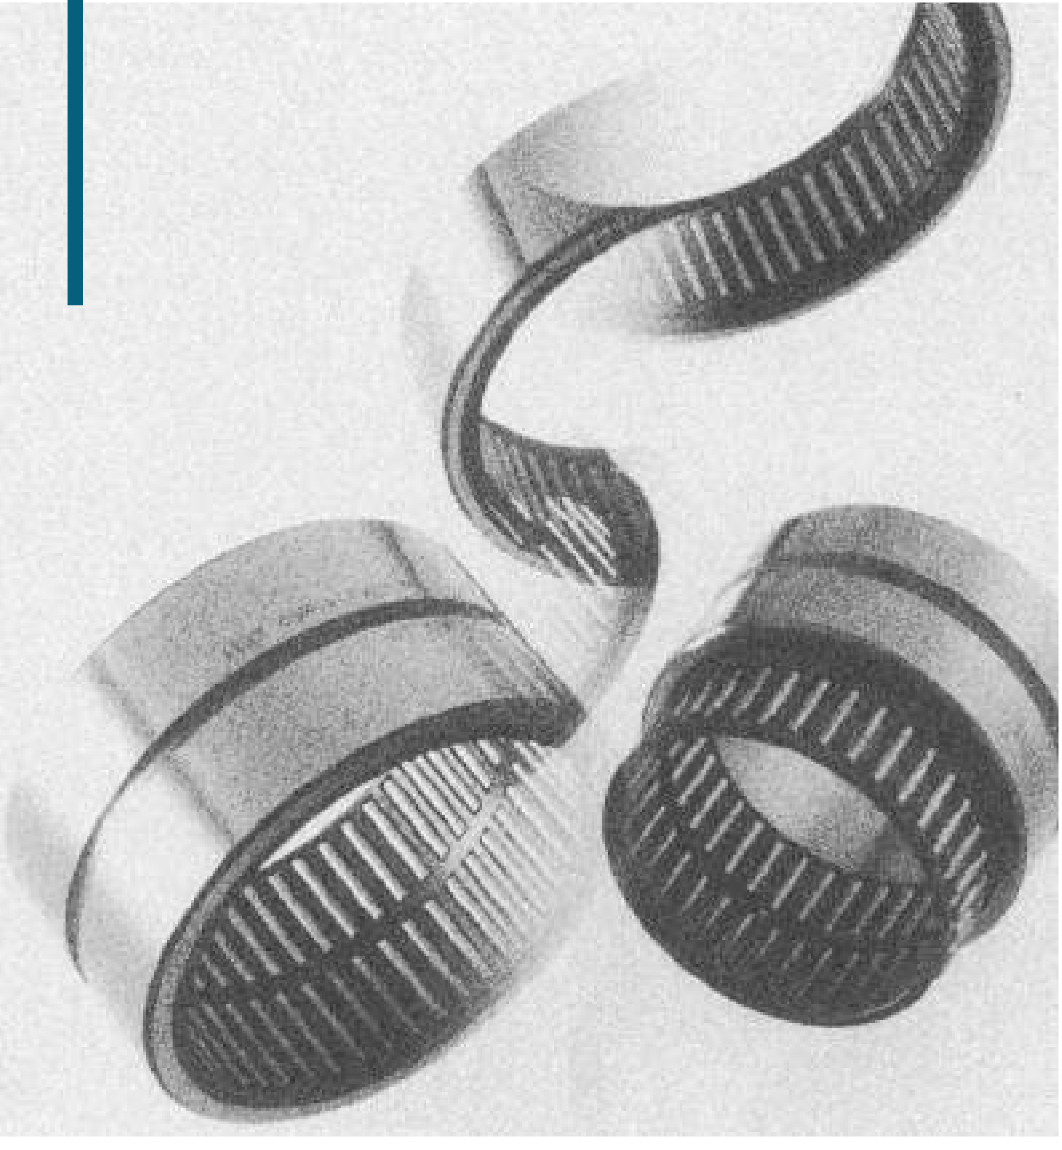
Machined Ring Needle Roller Bearings, Separable Type



Machined Ring Needle Roller Bearings, Separable Type

The machined ring of this bearing type has no rib or side plate and, hence, the outer ring and the needle roller and cage assembly are separable from each other.

The outer ring can't regulate axial displacement of the needle roller and cage assembly and, therefore, the bearing construction must be designed so that the needle roller and cage assembly can be guided by a shaft or a housing. Furthermore, the needle roller and cage assembly can be separated from the outer ring so that the cage and roller assembly, and the outer and the inner ring can be mounted on a shaft or a housing independent. This could facilitate the bearing mounting work.

This bearing type is suitable for an application requiring high running accuracy because the radial clearance can be selected to a narrow range by combining appropriate inner ring, outer ring and needle roller and cage assembly.

Bearing type	Applicable shaft diameter (mm)	Composition of bearing number	Remarks
Type RNAO 	φ5 – φ100	**RNAO－10×17×10 T2** Suffix Width Outer diameter Roller set bore diameter Type code **[Suffix]** T2 : Resin cage ZW: Double-row type	Bearing with suffix T2 uses a polyamide resin cage and, therefore, it shall be used at allowable temperature 120˚C and, under continuous running, at 100˚C and less. For applications required high running accuracy, manufacture of the bearings conforming to JIS Class-6, -5 and -4 is also available on special request.
Type RNAO··ZW 	φ8 – φ80		
Type NAO 	φ8 – φ90	**NAO－10×17×10 ZW** Suffix Width Outer diameter Bore diameter Type code **[Suffix]** T2 : Resin cage ZW: Double-row type	
Type NAO··ZW 	φ10 – φ70		

Accuracy of bearing

The dimensional accuracy, profile accuracy and running accuracy of machined ring needle roller bearing, separate type (with inner ring) are specified in JIS B 1514 (Accuracy of Rolling Bearings). (Refer to **Table 4.3** of Section 4. "**Bearing Tolerances**" on page A-26.) Although the accuracy of **NTN** standard bearings conforms to JIS Class-0, **NTN** can also supply bearings conforming to JIS Class-6, -5 and -4. Feel free to contact **NTN** for the further detail of these bearings.

The dimensional tolerances for the roller inscribed circle diameters (F_w) of the bearing type without inner ring conform to ISO Tolerance Range Class-F6. The outer ring and the needle roller and cage assembly are supplied in set and, therefore, the bearing must be installed with the combination of these two in set remained unchanged.

For applications that need particularly high running accuracy, certain bearing users install the inner ring onto the shaft and then grind the raceway surface to targeted accuracy. To fulfill this type of request, **NTN** will supply a special inner ring whose raceway surface includes a grinding allowance. For details, contact **NTN** Engineering.

Radial internal clearance and bearing fits

For information about radial internal clearance of **NTN** machined ring needle roller bearings, separable type (with inner ring), refer to **Table 5.1** in Sec. **5.1 "Bearing radial internal clearance"** (page A-30). Because of the narrow non-interchangeable clearance range, the bearings shipped after adjusted to a specific non-interchangeable clearance must be installed with the clearance remained unchanged.

The dimensional tolerances (fits) of a shaft and housing bore to which the bearing with inner ring is installed should be in accordance with type and magnitude of load, and dimensions of the shaft and housing bore. For information about the dimensional tolerances of a shaft and housing bore, refer to Sec. **6.4 "Recommended internal fits"** (page A-33). For the profile accuracy and surface roughness of the shaft and housing bore corresponding to the recommended internal fits in Table 8.3 in Sec. **8.3 "Shaft and housing accuracy"** (page A-40).

A bearing not having an inner ring directly uses the shaft as raceway surface, and the dimensional tolerances of the shaft diameter (raceway diameter) can vary depending on the operating internal clearance of the bearing as summarized in **Table 1** in page B-57. For this type of bearing usage, the dimensional tolerance class for the housing bore is K7, which is most commonly adopted tolerance class. When wishing to adopt a dimensional tolerance class other than K7 for the housing bore, contact **NTN** Engineering for technical assistance.

For the profile accuracy, surface roughness and surface hardness of the shaft that functions as raceway surface, refer to Sec. **8.4 "Raceway surface accuracy"** (page A-40) and Sec. **8.5 "Material and hardness of raceway"** (page A-40).

Oil hole dimension of the outer ring

The outer ring of bearing Type ZW is provided with an oil hole and an oil groove to facilitate oil lubrication to bearing.

Table 1 shows the oil hole dimension.

Table 1 Oil hole dimension

Outer ring outer diameter		Oil hole dia. (mm)	Number of oil hole
over	incl.		
—	20	2.0	1
20	40	2.5	1
40	80	3.0	1
80	200	3.5	1

Mounting relations

The inner ring and outer ring of any machined ring needle roller bearing, separable type must be positioned in axial direction by shoulder or a snap ring.

The mounting relation dimensions about the shaft and housing bore for this case are found in the relevant dimension table. The cage must be guided by the shaft or the side face of the housing shoulder, but the guide surface must be finished by, at least, grinding for deburring.

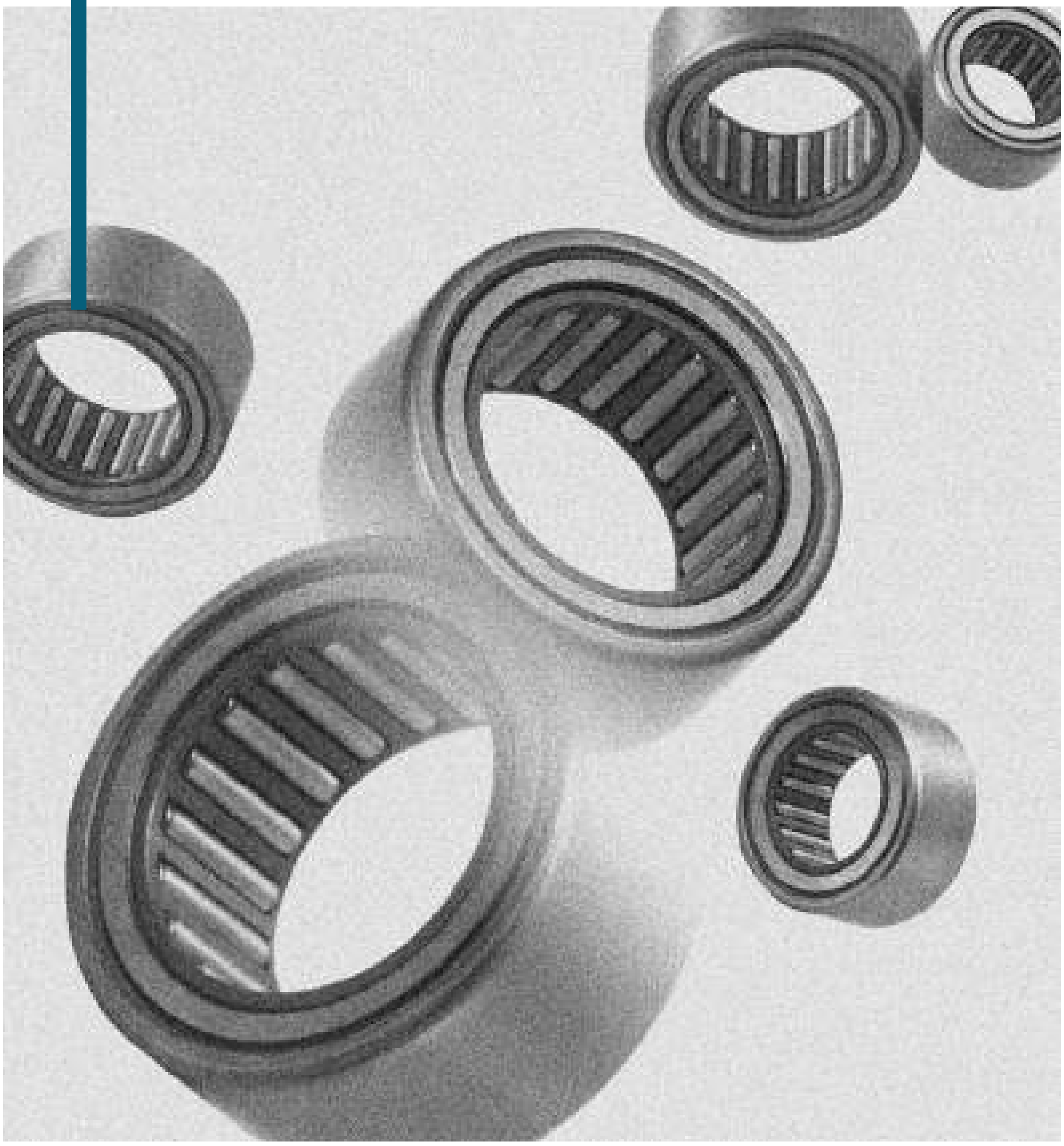
Self-Aligning Needle Roller Bearings



Self-Aligning Needle Roller Bearings

Self-aligning needle roller bearings each comprise an outer ring having spherical outside surface; a deep drawn steel collar around the outside surface of outer ring, and; a resin support ring situated between the outer ring and the collar so that the bearing can be automatically aligned; the inner ring alone can be separated from the bearing.

This bearing product has advantages that it can be used on a highly flexible shaft or in an area where alignment with the housing bore is difficult. Also, this bearing product is easy to handle: for example, it is axially positioned without using a snap ring by simply press-fitting into the housing bore in an appropriate fit mode.

Bearing type	Applicable shaft diameter (mm)	Composition of bearing number	Remarks
Type RPNA··R 	φ15– φ45	**RPNA 20 / 35 R** R: Suffix 35: Outer diameter 20: Roller set bore diameter RPNA: Type code **[Suffix]** R: Ribbed type	Maximum permissible temperature is limited to 100˚C because the bearing uses a resin-made support ring.
Type PNA··R 	φ12– φ40		

Bearing accuracy

The dimensional accuracy and profile accuracy of any **NTN** self-aligning needle roller bearing shall be per JIS Class 0 specified in JIS B 1514 "Rolling bearings—Tolerances". This does not apply to the outside diameter and width of precision drawn collar.

The dimensional tolerances of roller set bore diameter (F_w) of the type RPNA··R (w/o inner ring) shall fall in the range of ISO Tolerance Class F6.

Radial internal clearance and bearing fits

The **NTN** Type PNA··R self-aligning needle roller bearing (w/ inner ring) is manufactured to the tolerance range of radial internal clearance in **Table 5.1** in Sec. **5.1 "Bearing radial internal clearance"** (page A-30). As a self-aligning needle roller bearing is used after being press-fitted into a housing, the fits to the housing and shaft specified in **Table 1** in this page need to be satisfied so that the bearing can function correctly. The bore of this housing needs to satisfy the accuracy specified in **Table 2** in this page. For accuracy of a shaft that uses an inner ring, refer to **Table 8.3** in Sec. **8.3 "Accuracy of shaft and housing"** (page A-40); for accuracy of a shaft that is directly used as a raceway surface, refer to Table 8.4 in Sec. **8.4 "Accuracy of raceway surface"** (page A-40).

For material and hardness of the shaft that functions as raceway surface, refer to Sec. **8.5 "Material and hardness of raceway"** (page A-40).

Table 1 Fits with housing and shaft (recommended)

Housing		Shaft	
Iron	Light alloy	w/o inner ring	w/ inner ring
N6 (N7)	R6 (R7)	h5 (h6)	k5 (j6)

Table 2 Accuracy of housing bore (recommended)

Characteristic	Tolerance
Roundness (max.)	IT5/2
Cylindricity (max.)	IT5/2
Surface roughness (max.)	0.8a

Bearing mounting relation dimensions

Self-aligning needle roller bearing with an inner ring must be used within the permissible shift range **(S) (state where the rollers remain in contact with the inner ring in an effective contact length range).** The permissible shift (*S*) will be found in the relevant dimension table. When the axial shift of the intended bearing is large or a closing seal is used in close vicinity to this bearing, a wider inner ring needs to be adopted. Carefully use a closing seal as its sealing effect may be jeopardized when dimensional errors of fit and/or shaft deflection are large.

When installing a self-aligning needle roller bearing to a housing, place the jig on the marking side of the bearing, and then press-fit the bearing into the correct location in the housing bore.

When installing, NEVER directly hit the bearing with a hard tool such as a steel hammer. Instead, use the press-fit jig that is equipped with a mandrel fitted with an O-ring (see **Fig. 1** in this page). The bearing will be easily press-fitted as it will not be misaligned to the housing or fall.

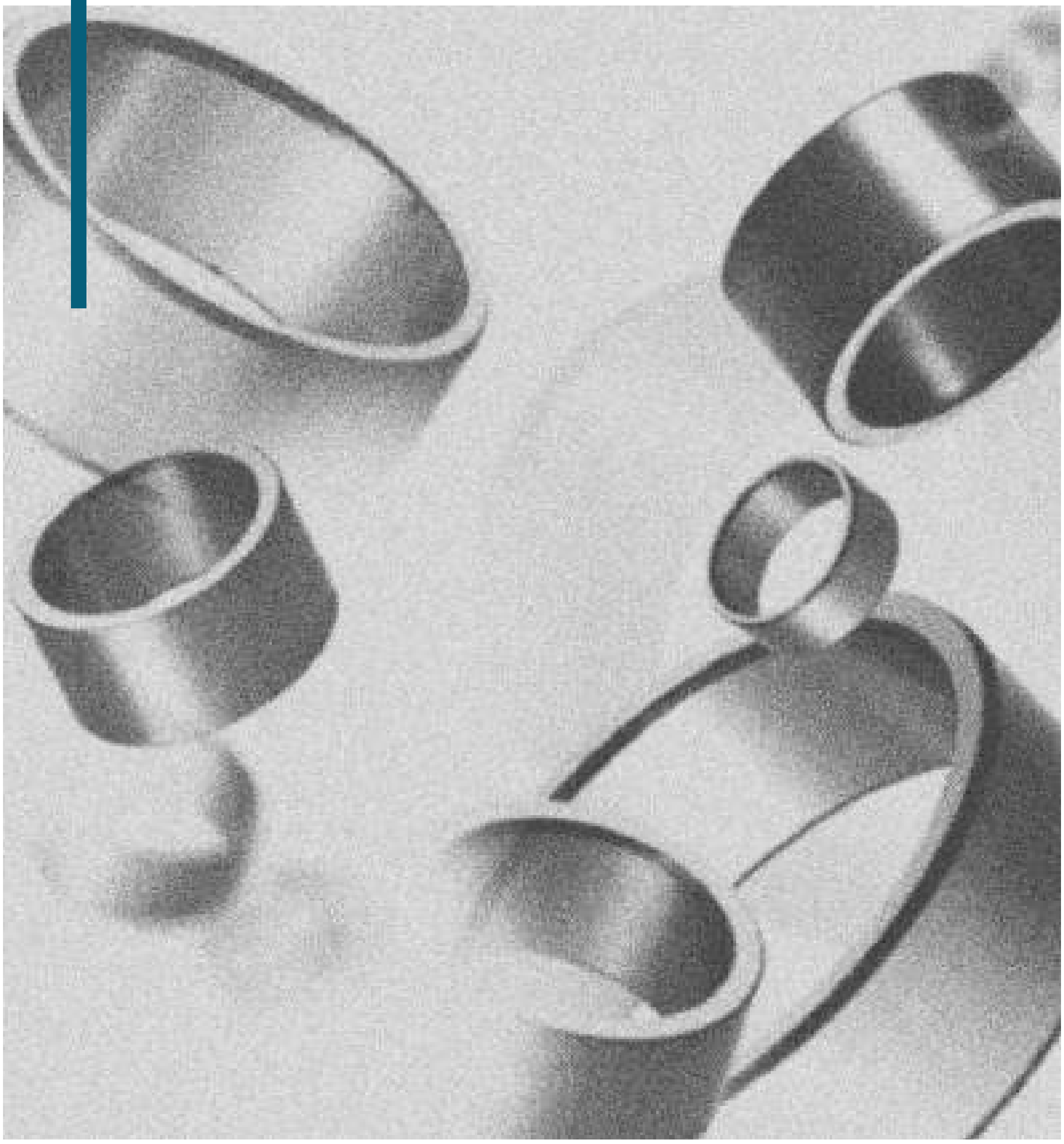
Note 1) Allowable minimum chamfer dimension. 2) Allowable axial stroking value of inner ring against outer ring.
Remarks: Type RPNA products are imports from INA (German company in Schaeffler Group).

Inner Rings



Inner Rings

Inner Rings

Many of the needle roller bearings use a shaft as the direct raceway surface without using inner ring. However, it is recommended to use any of the inner rings described hereunder, together with needle roller bearing, where applicable shaft can not be surface-hardened and surface-finished by grinding. Any inner rings are made of high carbon chrome bearing steel and finished by grinding after heat-treated.

It is desirable to use an inner ring of wide width, where the axial displacement of a shaft is great and also a seal is used at the outer side of bearing.

Types and Designs

NTN inner rings are available in both of **IR type** with boundary dimensions of metric system and **MI type** with boundary dimensions of inch system. Both edges of inner ring raceway are chamfered to form gentle tapers in order to facilitate fitting of the inner ring. In contrast, inner rings whose inner ring number is headed by an asterisk (*) are provided with slight-chamfering so that they will offer a greater axial travel. In addition to these inner rings, manufacture of special inner ring type (suffix D) with oil hole on its center is also available.

For applications that need particularly high running accuracy, certain bearing users install the inner ring onto the shaft and then grind the raceway surface to targeted accuracy. To fulfill this type of request, **NTN** will supply a special inner ring whose raceway surface includes a grinding allowance. For details, contact **NTN** Engineering.

Composition of inner ring number

Inner ring number consists of type code (**IR** or **MI**), dimension code [bore dia. (d)×raceway dia. (F)×width (B)] and a suffix. Note that the dimensions of Type **MI** (inch series) inner rings measure in 1/16 increments.

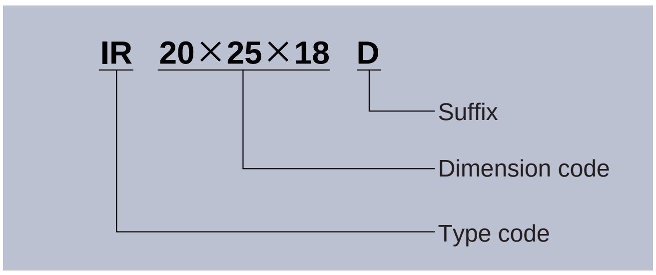


Fig. 1

Dimensional accuracy for inner ring

The dimensional accuracy (bore diameter "d", width "B" and chamfer dimension "$r_{s\,min}$"), profile accuracy and running accuracy of the inner rings are as shown in **Tables 4.3** and **4.5** of Section 4 "**Bearing accuracy**" (page A-26). And the standard accuracy class of these items conforms to JIS Class-0, but other inner rings conforming to JIS Class-5 and -4 are also offerable on request.

Each inner ring has been finished to the dimensional tolerance of its raceway diameter (F) in the relevant dimension table so that when the inner ring is combined with a needle roller bearing, the resultant radial internal clearance falls in a range of ordinary clearance (refer to **Table 5.1** in Sec. **5.2 "Running clearance"**.)

2) Allowable minimum chamfer dimension r. 3) Max. allowable dimension of radius r_a for corner roundness on shaft/housing.

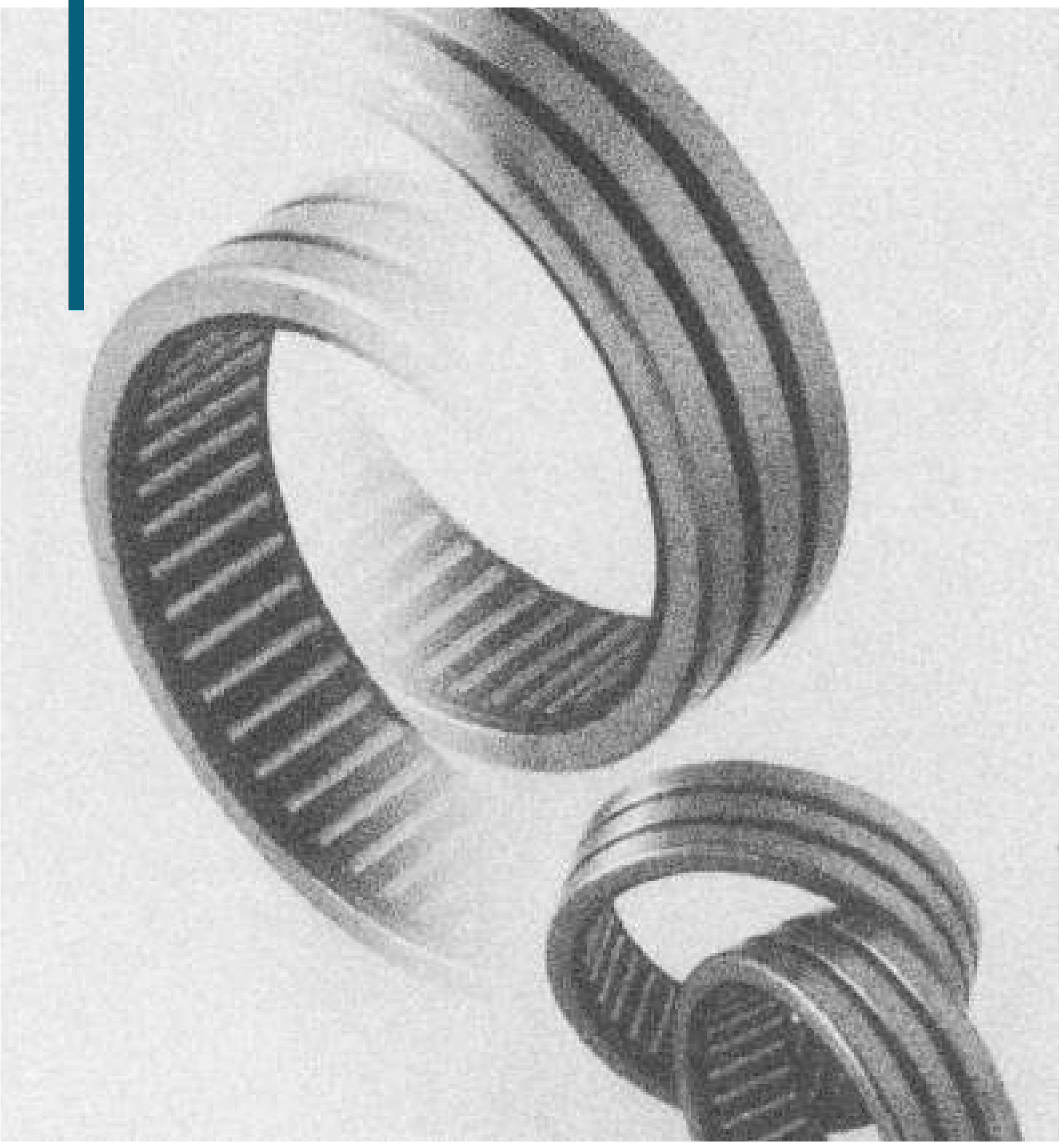
Adjustable-Clearance Needle Roller Bearings



Clearance-Adjustable Needle Roller Bearings

This bearing type comprises a solid outer ring with a unique cross-sections shape and needle rollers and cage built in the outer ring. The outer ring, needle rollers and cage are inseparable from each other. The outer ring raceway diameter is reduced by clamping the outer ring axially, which then reduces the roller inscribed circle diameter (F_w).

Axial clamping force on the bearing can be adjusted to alter the reduction on outer ring raceway diameter so that the radial clearance can be finely adjusted. The bearing is used on machine tools main spindle and other similar which require high speed rotational accuracy of JIS Class-4.

Bearing type	Applicable shaft diameter (mm)	Composition of bearing number	Remarks
Type RNA49··S 	ϕ30～ϕ125	**RNA 49 05 S** — Type code; Dimension series; Roller set bore diameter code; Suffix. **[Suffix]** S: Clearance-adjustable type	The dimensional accuracy, profile accuracy and running accuracy conform to JIS Class-4 so as to be available for applications requiring high running accuracy. Another inner ring type with grinding allowance for its raceway surface can also be supplied upon request.
Type NA49··S 	ϕ25～ϕ110		

Bearing accuracy

Application of this bearing type is limited to the portions of a machine which require high running accuracy. Therefore, the dimensional accuracy, profile accuracy and running accuracy of this bearing type conform to JIS Class-4. For applications that need particularly high running accuracy, certain bearing users install the inner ring onto the shaft and then grind the raceway surface to targeted accuracy. To fulfill this type of request, NTN will supply a special inner ring whose raceway surface includes a grinding allowance.

Radial internal clearance and bearing fits

The radial internal clearance of Type **RNA49··S** with inner ring is smaller than ordinary clearance. While the tolerance of roller set bore diameter (F_w) of Type **NA49··S** without inner ring is listed in the relevant dimension table, the radial internal clearance of the bearing is determined once the applicable shaft diameter has been selected.

To be able to force the outer ring in the axial direction to shrink the raceway diameter, the fit of the outer ring to the housing bore needs to be "transition fit" or "interference fit" (interference of approximately 5μm).

Bearing fit on a shaft and in a housing shall be per **Table 1.**

Table 1 Bearing fit in shaft and housing (recommended)

Bearing type	Shaft	Housing
RNA49··S	m5	K4
NA49··S	k5	

Shaft and housing accuracy

This bearing type which is applied to the portions of a machine requiring high running accuracy is clamped with the outer ring inclination in installing restrained as less as possible. Therefore, the profile accuracy of the shaft and the housing must be made higher than that for general machined ring needle roller bearings. (**Table 2**)

Table 2 Shaft and housing accuracy (recommended)

Characteristics	Shaft	Housing
Roundness (max)	IT2	IT3
Cylindricality (max)	IT2	IT3
Tolerance of shoulder runout (max)	IT3	IT3

Method for adjusting radial internal clearance

The ratio of outer ring axial shrinkage to shrinkage of roller inscribed circle diameter (F_w) is nearly 3:1. In other words, to be able to decrease the radial internal clearance of the bearing by 1μm, it is necessary to tighten the outer ring by 3μm in the axial direction.

When adjusting the radial internal clearance of a bearing, be careful to uniformly tighten its outer ring along the centerline of the shaft.

In the case of adjustment by the method illustrated in **Fig. 1**, the spacer is put between the housing and the lid. Changing the thickness of the spacer by wrapping the spacer width or replacing the spacer, a certain amount of axial clamping can be obtained.

In **Fig. 2**, the fixed ring is fitted in the housing and, thereafter, the threaded lid is screwed in until it comes in contact with the outer ring for zero setting. Then, the threaded lid is further screwed in by the required value, after the fixed ring was loosened, and thereafter the fixed ring is retightened. Further, it is recommended to use a saw-toothed tightening screw as illustrated in **Fig. 3** because accuracy-down can be minimized by use of such a screw.

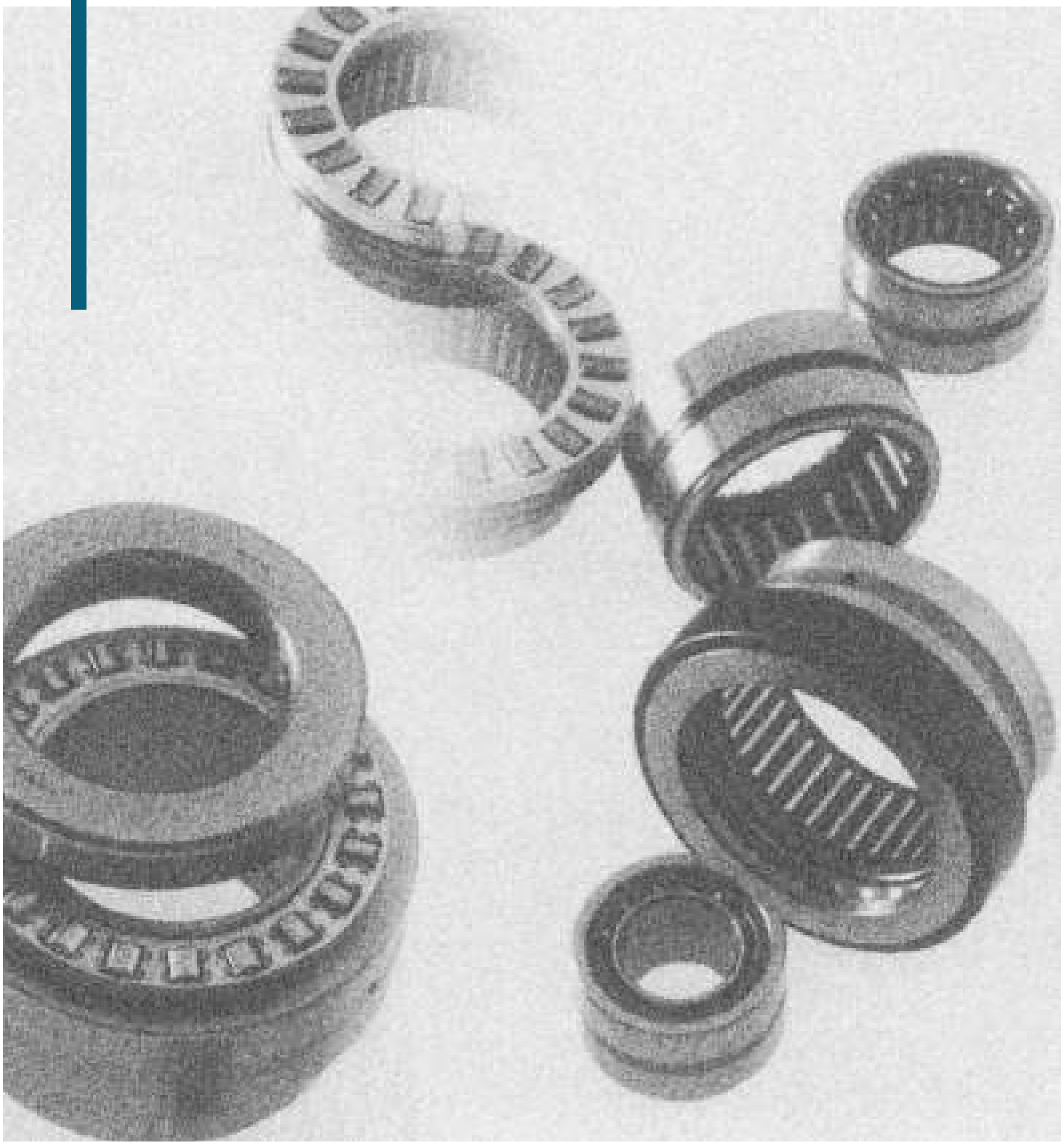
Complex Bearings



Complex Bearings

NTN complex bearing is comprised of a needle roller bearing of supporting radial load and a thrust bearing for supporting axial load which are assembled integrally. Comparing with individual use of a radial bearing and a thrust bearing for the same purpose, this complex bearing saves the required installation space and thereby can contribute to making the overall construction of an equipment more compact.

Bearing type	Applicable shaft diameter (mm)	Load capacity	Composition of bearing number
Type NKX 	φ10—φ70		**NKX 20 T2** Suffix T2: Resin cage Dimension code (shaft diameter) Type code
Type NKX··Z 			**NKX 20 T2 Z** Suffix T2: Resin cage Z: with dust-proof cover Dimension code (shaft diameter) Type code
Type NKXR 	φ15—φ50		**NKXR 20 T2** Suffix T2: Resin cage Dimension code (shaft diameter) Type code
Type NKXR··Z 			**NKXR 20 T2Z** Suffix T2: Resin cage Z: with dust-proof cover Dimension code (shaft diameter) Type code
Type NKIA 	φ15—φ70		**NKIA 59 04** Bore diameter code Dimension series code Type code
Type NKIB 	φ15—φ70		**NKIB 59 04 R** Suffix R: outer ring with rib Bore diameter code Dimension series code Type code
Type AXN 	φ20—φ50		**AXN 20 52** Outer diameter code Bore diameter code Type code
Type ARN 	φ20—φ70		**ARN 20 62** Outer diameter code Bore diameter code Type code

※Each listed load capacity is subject to reference bearing bore diameter of φ20.

Bearing components	Handling characteristic	Features
Inscribed circle diameter (shaft dia.) : φ20 Radial bearing : Needle roller type Iron cage Thrust bearing : Ball type Resin cage Dust-proof cover : without Thrust plate : Separable	△ Separable thrust plate Without dust-proof cover	Can be applied to high speed running under light axial load, due to use of ball type thrust bearing.
Inscribed circle diameter (shaft dia.) : φ20 Radial bearing : Needle roller type Iron cage Thrust bearing : Ball type Resin cage Dust-proof cover : with Thrust plate : Non-separable, integral type	○ Integral thrust plate With dust-proof cover	This type is identical to Type NKX except in that the thrust bearing is protected with a dust cover. Furthermore, the handling characteristic is good because the dust cover makes the thrust plate non-separable integral.
Inscribed circle diameter (shaft dia.) : φ20 Radial bearing : Needle roller type Iron cage Thrust bearing : Cylindrical roller type Resin cage Dust-proof cover : without Thrust plate : Separable	△ Separable thrust plate Without dust-proof cover	Due to the use of needle roller bearing as its thrust bearing, this type can support greater axial load than NKX.
Inscribed circle diameter (shaft dia.) : φ20 Radial bearing : Needle roller type Iron cage Thrust bearing : Cylindrical roller type Resin cage Dust-proof cover : with Thrust plate : Non-separable, integral type	○ Integral thrust plate With dust-proof cover	This type is identical to NKXR, but its thrust bearing is provided with dust-proof cover to prevent grease scattering. Furthermore, the handling characteristic is good because the dust-proof cover makes the thrust plate non-separable and integral.
Inscribed circle diameter (shaft dia.) : φ20 Radial bearing : Needle roller type Thrust bearing : Angular type	◎ Integral angular bearing Inner ring separable	This type is composed of needle roller bearing and angular bearing which were integrated into one unit. The angular bearing supports axial load. Hence, this type can support one-way axial load only. Best-suited to high speed and light load application.
Inscribed circle diameter (shaft dia.) : φ20 Radial bearing : Needle roller type Outer ring with rib Thrust bearing : Three-point contact angular type	○ Double inner ring type Inner ring separable	This type is composed of needle roller bearing and three-point contact angular bearing which were integrated into one unit. Unlike KN1A, this type can support bi-directional axial load.
Inscribed circle diameter (shaft dia.) : φ20 Outer ring outer diameter : 52 Radial bearing : Needle roller type Thrust bearing : Needle roller type	△ Separable	This type is a special-purposed bearing to support a precision ball screw. This type uses the side face of the radial bearing as the raceway surface of thrust bearing. This can support axial load from both directions.
Inscribed circle diameter (shaft dia.) : φ20 Outer ring outer diameter : 62 Radial bearing : Needle roller type Thrust bearing : Cylindrical roller type	△ Separable	This type is a special-purposed bearing to support a precision ball screw. This can support bi-directional axial load. This type is identical to AXN, but its axial load capacity is greater.

Bearing Accuracy

Regarding the dimensional tolerances for radial needle roller bearing, refer to **Table 4.3** 4. "**Bearing Tolerances**" (page A-26) for others than the characteristics described in Dimensions Table and to **Table 4.4** (page A-26) for thrust bearing tolerances respectively. Manufacture of bearing **Type AXN** and **ARN** is limited to those of JIS accuracy class-5 and -4 only. (Allowable radial run-out values for Type AXN and ARN is as specified in **Table 1**.)

Table 1 Allowable radial run-out values for Type AXN and ARN

Unit: μm

Nominal bearing bore dia. d or nominal bearing outer dia. D (mm)		Radial runout of ❶ radial inner ring K_{ia}		Allowable radial ❷ run-out for outer ring K_{ea}	
Over	Incl.	Class 5	Class 4	Class 5	Class 4
18	30	4	3	—	—
30	50	5	4	—	—
50	80	5	4	8	5
80	120	—	—	10	6
120	150	—	—	11	7

❶ To be determined based on "d".
❷ To be determined based on "D".

Radial internal clearance

The radial internal clearance of **Type NKX+IR, NKXR+IR** and **NKIA** is in accordance with the interchangeable clearance information in **Table 5.1(1)** in Sec. **5.1 "Bearing radial internal clearance"** (page A-30). The standard bearings are manufactured subject to the regular clearances.

The radial internal clearance of **Types AXN** and **ARN** is unique to this type, and the clearance value specific to an intended bearing is found in the relevant dimension table.

Bearing fits

Radial needle roller bearings shall be fitted on shaft/in housing in compliance with **Table 2**. The thrust bearing washers of **Type NKX** and **NKXR** shall be fitted in a housing with hole diameter larger by 0.5mm or over than the washer outer diameter D_1 or D_2. For **Type NKIA** and **NKIB** it is not allowed to make the interference greater than k5/M6.

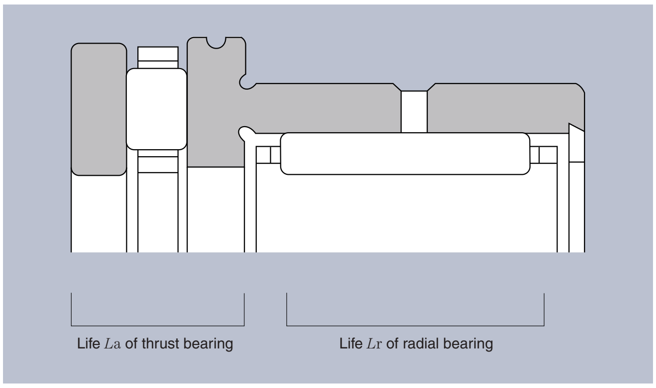
Table 2 Bearing fit on shaft and in housing (recommended)

Bearing type	Shaft	Housing
Series NKX, NKXR	k5	K6 (M6)
Series NKIA, NKIB	k5	M6
Series AXN, ARN	j5	J6

Remarks: The parenthesized housing code is applied, where high rigidity is required.

Calculation of rating life

The rating life (L) of any complex bearing is determined as follows. Determine individually the rating life (L_r) of radial needle roller bearing from radial load acting thereon and the rating life (L_a) of thrust bearing from axial load acting thereon. And determine the rating life (L) from these determined rating lives (L_r, L_a) using the following formula.



Rating life L of complex bearing

$$L=\frac{1}{\left(\frac{1}{L_r^{1.1}}+\frac{}{L_a^{1.1}}\right)^{0.91}} \quad \cdots\cdots(1)$$

Note 1) Allowable minimum chamfer dimension r 2) Max. allowable dimension of radius r_{as} for corner roundness on shaft/housing.
Remarks: 1. This complex can support bi-directional axial load.
2. The ball bearing of this complex bearing is complete with a synthetic resin cage, and the allowable operating temperature shall be 120˚C and, under continuous running, 100˚C or les
3. This bearing type is the imported product from INA, Germany.

Cam Followers / Roller Followers

Cam Followers (Stud Type Track Roller)

This is a track roller complete with stud instead of inner ring, which is designed to operate with its outer ring rolling on the track. These NTN stud type track rollers are applied to eccentric roller, guide roller, rocker arm roller, etc. similarly to the roller followers. One end of the stud is threaded and the hexagonal nut is used to be mounted easily.

The cam follower types marked with a suffix including "F" are product per new standard specification. They are identically to the conventional products in terms of fitting method and lubrication method, but boast improved functionality through crowned rollers and special heat

Follower type	Applicable shaft diameter (mm)	Load capacity	Composition of bearing number
KRM··XH 	ϕ1.5—ϕ6	—	**KRM 4 XT2H / 3AS** Suffix X: Cylinder outer diameter T2: Resin cage H: Hexagonal socket 3AS: Grease Dimension code Type code
KRMV··XH 	ϕ1.5—ϕ6		**KRMV 4 XH / 3AS** Suffix X: Cylinder outer diameter H: Hexagonal socket 3AS: Grease Dimension code Type code
KR **CR** 	**KR**: ϕ3—ϕ30 **CR**: ϕ4.826—ϕ22.225	 **KR90**	**KR 16 FD02H / L588** Suffix F: New standard specification D0: w/o oil hole T2: Resin cage H: Hexagonal socket L588: Grease Dimension code Type code
KRT 	ϕ6—ϕ30		**KRT 32 X** Suffix X: Cylinder outer diameter Dimension code Type code
KRV **CRV** 	**KRV**: ϕ3—ϕ30 **CRV**: ϕ4.826—ϕ63.5	 **KRV90**	**KRV 22 FXLLH / 3AS** Suffix F: New standard specification X: Cylinder outer diameter LL: Seal H: Hexagonal socket 3AS: Grease Dimension code Type code
KRVT 	ϕ6—ϕ30		**KRVT 52 XLL / 3AS** Suffix X: Cylinder outer diameter LL: Seal 3AS: Grease Dimension code Type code

※Each listed load capacity is subject to the reference bearing diameter of ϕ30.

treatment. Note that the cam follower types having a suffix including “F” but lacking an oil hole are prefilled with urea-based high-functionality grease and are identified with a suffix including “DO”.

The outer ring is guided in the axial direction with a flange at the end of stud and the side plate press-fitted to the stud.

The outer ring has a thick wall and both of spherical outer profile and cylindrical outer surface (tail code: **X**) are available for it similarly to the outer ring of the roller follower.

Follower components	Features
Outer ring outer diameter: φ4 With metric series cage Outer profile: Cylindrical Stud head: Hexagonal socket Cage: Resin cage Grease: Prefilled	● Polyamide resin cage (T2 suffix) can operate at temperatures up to 120˚C (100˚C for continuous operation). ● Prelubricated (no relubrication hole)
Outer ring outer diameter: φ4 Metric series full complement roller type Outer profile: Cylindrical Stud head: Hexagonal socket Grease: Prefilled	● Better for heavy loads than KRM··XH type. ● Prelubricated (no relubrication hole)
Outer ring outer diameter: φ16 With metric series cage New standard specification Without oil hole Without seal Outer profile: Spherical Stud head: Hexagonal socket Cage: resin cage Grease: Prefilled	● Standard cage is pressed steel. ● Polyamide resin cage (T2 suffix) is also available. Allowable temperature: 120˚C max. Continuous operating temperature: 100˚C max ● Suited to high speed. ● Due to a high initial grease fill, this type can be used for a long period of time without additional greasing. ● The standard Type KRT follower has no hexagonal hole (H suffix), but a hexagonal socket is standard with a threaded plug. ● If there is no grease code, the follower is not prelubricated.
Outer ring outer diameter: φ32 With metric series cage Stud head: with recessed slot for screw-driver use and tapped hole Outer surface profile: Cylindrical Seal: w/o seal Grease: Not prefilled	
Outer ring outer diameter: φ22 Metric series full complement roller type New standard specification Stud head: Hexagonal socket Outer surface profile: Cylindrical Seal: w/ seal Grease: Prefilled	● Suited to high load. ● Lower allowable running speed than caged types. ● Grease replenishing interval must be shortened due to the small internal volume available for grease. ● The standard Type KRVT follower has no hexagonal hole (H suffix), but a hexagonal socket is standard with a threaded plug.
Outer ring outer diameter: φ52 Metric series full complement roller type Stud head: with recessed slot for screw-driver use and tapped hole Outer surface profile: Cylindrical Seal: w/ seal Grease: Prefilled

Bearing accuracy

The dimensional accuracy and profile accuracy of cylindrical roller outer diameter (D) and outer ring width (C), and the running accuracy of bearing assy are as shown in **Tables 4.3** and 4.4 of Section 4 "**Bearing Tolerances**" (page A-26) and the accuracy class of each conforms to JIS Class-0. The dimensional accuracy of spherical outer diameter (D) and stud diameter (d_1) are as shown in applicable Dimensions Table.

Bearing fit and radial internal clearance

Table 1 shows the recommended fitting tolerance for the stud mounting hole.

And **Table 2** shows the radial internal clearance.

Table 1 Recommended tolerance

Classification	Tolerance range class for mounting hole

Fitting relations

(1) Make the face height at the cam follower mount greater than "e" dimension given in applicable Dimension Table. (**Fig.1**)
Furthermore, chamfer the stud mounting hole at R as small as possible (around 0.5×45°) and bring the side faces of side face in precise contact.

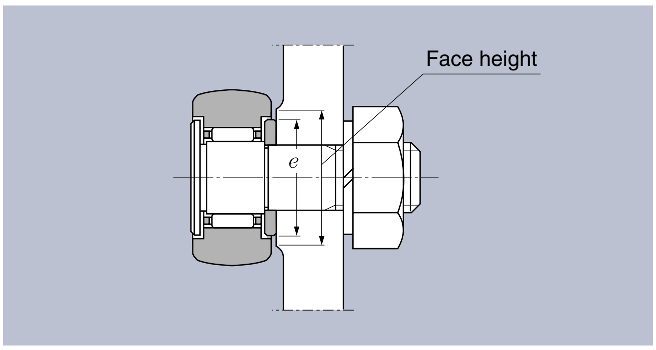

Fig. 1

(2) Don't hammer directly the cam follower rib. Doing so would cause breakdown and rotation failure of the rib.

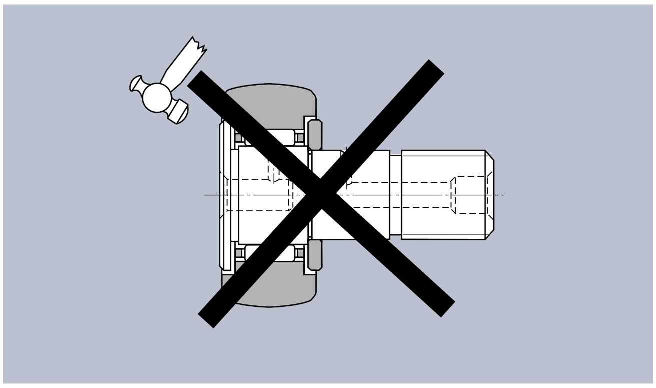

Fig. 2

(3) The oil hole position on the stud raceway surface is shown with **NTN** mark stamped on the stud rib surface. Mount the stud so the oil hole locates within the non-load area (non-load side). (**Fig. 3**) If the oil hole locates within the load area, it would cause shorter life of the follower.(4) Particularly where loose

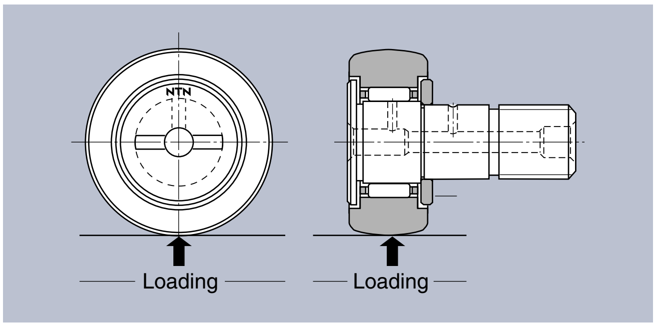

Fig. 3

of the mounting screw is forecast due to wide amplitude vibration during running, the mounting methods as illustrated in **Fig. 4** are available.

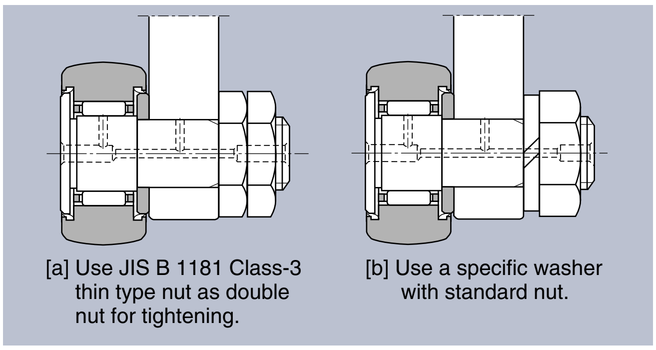

Fig. 4

(5) The stud is subjected to bending stress and tensile force arising from bearing load. Tighten the stud screws with tightening torque which does not exceed the torque value specified in applicable Dimension Table. **Too tight tightening torque could result in rupture of the threaded portion.**

(6) A hole is provided on the stud center at right angle to the shaft axial center, as illustrated in **Fig. 5**. Use this hole for locking or grease replenishment.

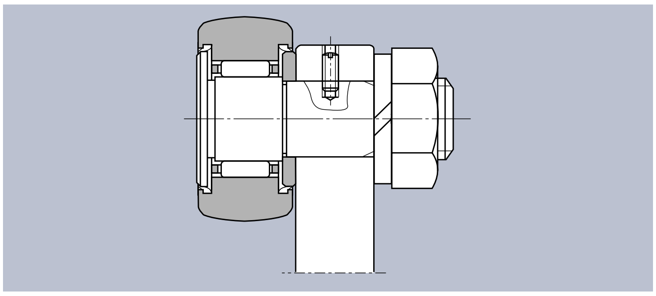

Fig. 5

(7) For mounting and adjusting the eccentric stud type cam follower, follow the sequence given hereunder.

1. Insert the stud into the mounting hole such that the **NTN** mark (oil hole position) is located relative to the load acting direction as shown in **Fig. 3**. Then, lightly tighten the nut. Be sure that the stud remains capable of turning.
2. Fit the tip of flat blade screwdriver into the slot on the stud head or insert an Allen key into the socket of the hexagonal socket head plug (included with the cam follower) fastened into the stud; then turn the stud to adjust the gap between the cam follower to the mating contact surface.
3. After completion of gap adjustment, tighten the nut to the tightening torque listed in the relevant dimension table in order to jam the stud.

Usually, NTN cam followers are each mounted in cantilever configuration: consequently, when used for a prolonged period, fit of a cam follower to a corresponding bearing can get loose, and a non-uniform load (biased load) can eventually act on the bearing. To keep the machinery having NTN cam followers, it is necessary to prevent excessive loosening of the cam followers.

Lubrication and how to feed and replenish grease into the follower

Lubrication

The types having a synthetic rubber seal (suffix LL) and the full complement roller types are prefilled with lithium soap grease (grease code: 3AS), while the new standard specification bearing (w/o oil hole) is prefilled with urea-based high-functionality grease (grease code: L588), thereby these bearing types may be used in a temperature range of -20 to +120˚C or can be continuously used at a temperature of 100°C or lower. When a bearing is always used a temperature of 0˚C or lower, use of a bearing prefilled with cold temperature grease. For more information, contact **NTN** Engineering.

Bearings having a cage, but lacking a seal, do not have prefilled grease. (This description does not apply to bearings whose stud lacks an oil hole.)

If a prefilled grease is needed, feel free to contact **NTN**.

Note that **NTN** offers its unique bearing products prefilled with solid grease: these bearings feature minimized outward leakage of lubricant.

For bearing applications that need to minimize possible release oil mist into the atmosphere, **NTN** will offer bearings prefilled with low dusting grease. For more information, contact **NTN** Engineering.

The outer ring outer surface of bearing and the track surface must both be lubricated. Lack of lubrication for these surfaces can lead to premature bearing failure.

How to feed and replenish grease

Use a tool such as a grease gun to inject grease into a grease nipple installed to the end face of flange or end face of threaded side of the stud. In this case, plug the grease-feed hole or the tapped hole at non-greasing side (with a special-purposed plug or a threaded plug with hexagon socket.)

These grease nipple and plug are enclosed in each cam follower package. Screw-in them in specific position before mounting the cam follower.

Special grease nipple and that specified in JIS Standard as applicable are available for use. The dimensions thereof and the applicable bearing types are as specified in **Tables 3** and **4** respectively.

Furthermore, special press-fit type plug and threaded plug with hexagon socket are available for use. The dimensions thereof and the applicable bearing types are as specified in **Tables 5-1**, **2** and **Table 6** respectively.

When using the special-purposed press-fit plug, press-fit it in the grease feed hole using a mandrel of applicable dimension shown in **Table 7**.

Track load capacity of cam follower and roller follower

The reference hardness (reference tensile stress) was set up from the relationship between the follower hardness and net tensile stress of the material and the track load capacity was determined from the relationship of the setup reference stress to hertz stress.

How to set up the reference hardness (tensile stress) differs a little bit depending on each bearing manufacturer. Herein, the relevant Table appended to "JIS Handbook for Irons and Steels" was used as the hardness - tensile stress relationship.

(Approximate values per Hardness Conversion Table SAE J 417)

For HRC40, σ = 1.245MPa (127kgf/mm^2) was adopted as the reference hardness (tensile stress).

<Track load capacity adjustment factor>

The tensile stress of a material for cam follower is greater with increase in material hardness, and, at the same time, the load capacity of the track will be greater. The resultant track load capacity can be determined by multiplying a track load capacity found in the relevant dimension table by an appropriate track load adjustment factor found in **Table** 8 "Track load adjustment factor". **If the calculated track load capacity exceeds the basic static load rating C_{or} of the cam follower in question, then take C_{or} as the track load capacity of that cam follower.**

Note) The track load capacity determined herein is based on net tensile stress as the reference, not allowable hertz stress. Generally stress (specific stress) resulting in creep of follower material is greater than the tensile stress. Particularly in the case of static load, this track load capacity comes to a safety side value.

[Ex.] Determination of load capacity T_c' of track with certain hardness by use of track load capacity adjustment factor.
Assuming track load capacity described in Dimensions Table as T_c and track load capacity adjustment factor at applicable hardness as G respectively, the track load capacity T_c' can be determined as follows.

$$T_c' = G \cdot T_c$$

For hardness HRC50 at KR35XH,

T_c = 11 900N (1 220kgf), G = 1.987

$\therefore T_c'$ = 1.987 × 11 900N (1 220kgf)

= 23 645N (2 424kgf)

Since the basic static load rating C_{or} of the KR35XH is 17,900 N (1,830 kgf), and, accordingly, $T_c' > C_{or}$, track load capacity is assumed to be the value of C_{or}, that is, 17,900 N (1,830 kgf).

Reference (Track load capacity calculation process)

● For a cylindrical outer ring

$$\sigma_{max} = 190.7 \sqrt{\frac{T_c \Sigma\rho}{B_{eff}}} \quad N$$

$$= 60.9 \sqrt{\frac{T_c \Sigma\rho}{B_{eff}}} \quad kgf$$

● For spherical R outer

$$\sigma_{max} = \frac{856.8}{\mu\nu} \sqrt[3]{(\Sigma\rho)^2 T_c} \quad N$$

$$= \frac{187}{\mu\nu} \sqrt[3]{(\Sigma\rho)^2 T_c} \quad kgf$$

σ_{max} = 1 245MPa (127kgf/mm^2)

T_c : Track load capacity N (kgf)

Σ_ρ : Sum of curvature

B_{eff} : Effective contact length mm
Herein (Outer ring width - chamfer)

$\mu\nu$: Factor being determined by curvature

Outer ring strength

Generally any outer ring never breaks down as long as the load acting it is a usual operating load. This paragraph describes hereunder the strength calculation method to be used when the outer ring strength under shock load and heavy load is reviewed.

The outer ring strength can be determined using the formula given hereunder, assuming the respective outer ring profiles as illustrated in **Fig. 6**. In this case, the outer ring rupture strength means the bridged rupture strength of roller.

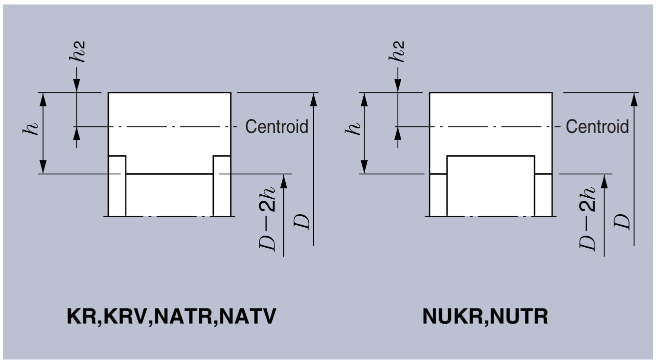

Fig. 6

Regarding how to set up breaking stress, in general 1760MPa [180kg/mm²] can be set up as the breaking stress for bearing steel, but it is desirable to set up the breaking strength with safety-side value (1170MPa [120kgf/mm²]), where stress concentration is taken into account. Generally any outer ring never break down as long as the load acting on it is usual operating load, but it necessary to check the rupture structure of outer ring, where shock load and heavy load act on it.

Incidentally, the stress acting on the outer ring in the bearing in ordinary use should be 196 MPa [20kgf/mm²] or smaller.

$$P=\frac{4\pi}{1+f(\alpha)}\times\frac{D-2h}{h(D-2h^2)^2}\times I\times\sigma$$

Where,

$$f(\alpha)=\frac{(\pi-\alpha)\sin\alpha-(1+\cos\alpha)}{2\cos\alpha}$$

$$\alpha=\frac{\pi}{Z}\ \text{(rad.)}$$

P : Breaking load (N)
I : Secondary moment of outer ring section (mm⁴)
Z : Number of rollers
σ = Breaking stress (MPa)
D, h, h_2 : per **Fig. 6** (mm)

Stud strength

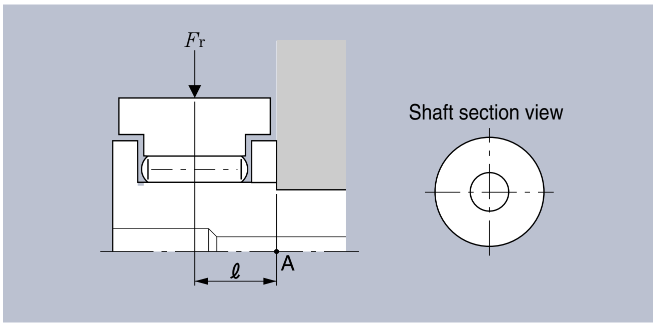

Fig. 7

When load Fr acts on the center point of outer ring as illustrated in **Fig.7**, bending moment $F_r\cdot\ell$ generates and consequently bending stress σ_1 (deemed as tensile stress) acts on the stud surface. In addition to this bending stress, tensile stress σ_2 generates from screw tightening because the stud itself is clamped to machine body with nuts. The stud strength can be reviewed from comparison of the sum ($\sigma_1+\sigma_2$) of these two tensile stresses with allowable stress σ for the stud material.

$$\sigma_1+\sigma_2<\sigma$$

$$\sigma_1=\frac{F_r\cdot\ell}{Z}$$

F_r : Maximum radial load
Z : Coefficient of shaft section through Point-A

$\sigma_2 \fallingdotseq 98$MPa (10kgf/mm²)
Tensile stress generating from maximum tightening torque described in "Dimensions Table"

σ : Allowable stress for material
The following values are adopted from the repeated bending test result of the stud material.
Where the stud material is subjected to static bending stress;
σ = 1372MPa (140kgf/mm²)
Where the stud material is subjected to repeated bending stress (single direction)
σ = 784MPa (80kgf/mm²)
Where the stud material is subjected to repeated bending stress (double directions)
σ = 392MPa (40kgf/mm²)

Accordingly,

$$F_r<\frac{Z}{\ell}(\sigma-\sigma_2)$$

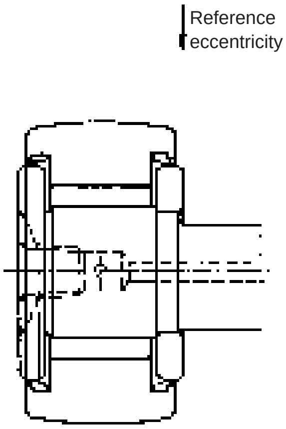
Note 1) JIS Class 0 is the dimensional tolerance of the outside diameter *D* of the outer rings of the KRVU··X and KRVU··XLL types whose outside surface form is cylindrical
2) The grease replenishment port is situated only in the front (in the left side face in the diagram above).



KRVU··LL type
(Full-complement roller type, with seal)

Note: The limiting speed of cam followers incorporating a seal (those marked with an asterisk) is approximately 10,000 min^{-1}

Roller Followers (Yoke Type Track Rollers)

NTN Yoke Type Track Rollers are the rolling mechanisms whose outer ring rolls on a track. For example, these track rollers are applied to eccentric roller, guide roller, rocker arm roller, cam roller and pressure roller. For that, the outer ring is designed to a wall thickness so as to be resistible to high load and shock load.

load. Both spherical outer surface (rolling surface) and cylindrical outer surface are available for the outer rin The spherical outer ring can withstand edge-load actin on the contact surface between the track and the tr roller, while the cylindrical outer ring (Tail code: X) track load capacity greater than the spherical outer ri

Bearing type	Applicable shaft diameter (mm)	Load capacity	Composition of bearing number

Bearing Tolerances

The dimensional accuracy, and profile accuracy and running accuracy about the bearing bore diameter (d), cylindrical roller outside diameter (D), outer rind width (C), and inner ring width (B) of the **Types NAB2 and NAB22** are as listed in **Table 4.3 Sec. 4 "Bearing accuracy"** (page A-26) (JIS Accuracy Class 0). The accuracies, and tolerances of assembled inner ring width (B), and spherical outside surface diameter (D) of the Type NACV, as well as the dimensional tolerances of roller set bore diameter (F) of the **Types RNAB2 and RNA22** are listed in the relevant dimension table.

Radial internal clearance and bearing fits

The tolerance class of a shaft to which a bearing having inner ring is installed shall be g6 (h6): when the shaft is directly used as a raceway surface (Types **RNAB2** and **RNA22**), the tolerance class of the shaft shall be k5 (k6). In general, the outer ring is not fitted in a housing. Mounting relations

Table 1 Radial internal clearance Unit: μm

80	100	0	35	20	55	35	75	70	115

Installation

(1) The side face height in the roller follower mount must be made larger than "e" dimension described in applicable Dimensions Table. (**Fig.1**) In mounting, chamfer the mounting surface at R as small as possible (around 0.5×45°) and bring the inner ring and the end face of side plate in precise contact one another.

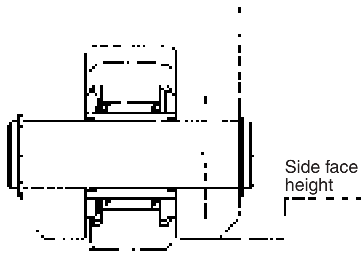

Fig.1

(2) Where the roller follower is mounted, locate the ring oil hole within the non-load area (load free (**Fig. 2**)
If the oil hole locates within the load area, it wo cause shorter life.

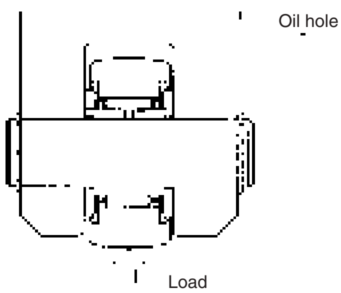

Fig.2

(3) The **Types RNAB2, NAB2, RNA22 and NA22** feature separable configuration. Their outer ring is guided a flange or thrust washer mounted onto the shaft (pin). Therefore, the guide surface needs to be finished at quality better than that obtained from turning: also, burrs must be thoroughly removed to achieve much smoother surface.Therefore, the guide surface must be finished more precisely than by turning and deburred completely for surface

Track roller components	Features
Inscribed circle diameter : ϕ50 Double-row cylindrical Full-complement roller type Labyrinth seal Outer profile spherical Grease: Prefilled	● High load rating, best-suited to applications subjected to high load and shock load. ● A steel plate is press-fit into the outer ring to form a labyrinth with the side plates on both sides of the inner ring, and the side plates are held so as not to separate from one another and make a good seal. ● The inner ring and the side plates are tightened together in axial direction to prevent axial movement. ● The outer ring is guided in axial direction by the outer ring ribs and the end faces of cylindrical rollers. Type NUTW provides the following additional features.
Inscribed circle diameter : ϕ25 Double-row cylindrical Full-complement roller type with center rib Labyrinth seal Outer profile : spherical Grease: Prefilled	● The highest load rating of all roller follower types. ● Due to the outer ring with inner rib, this type is good for axial and moment loads and runs smoothly depending on actual operating conditions. ● Good lubrication and longer life can be expected due to increase grease fill volume.

smoothing. In addition, when the guide surface is hardened the outer ring must be guided at A-dimension shown in **Fig.3**. When it is hardened, a little smaller guide surface can be used.

During assembly of the **Types RNA22** and **NA22**, be very carefully not to curl the lip of seal or damage the seal.

$A \geqq \frac{1}{2}(D+e)$

For D and e dimensions refer to applicable Dimensions Table.

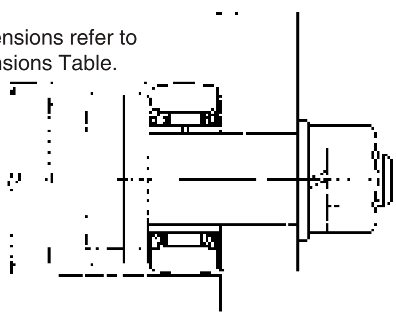

Fig.3

Where any of NTN roller followers was stub-mounted, non-uniform load (bias load) could act on the bearing, inversely affected by fitting loose arising from further continued running.
Good care must be exercised of such fitting loose, for stable running of the equipment.

Lubrication

The types having a synthetic rubber seal (suffix LL) and the full complement roller type are prefilled with lithium soap grease, thereby these bearing types can be used in a temperature range of -20 to +120°C or can be continuously used at a temperature of 100°C or lower. When a bearing is always used a temperature of 0°C or lower, use of a bearing prefilled with cold temperature grease. For more information, contact **NTN** Engineering.

Lubricant feeding and replenishing into the bearing are done through an oil hole provided on the inner ring. In case, even the inner ring must be fitted so the oil hole located within non-load area. For the full complement roller type roller followers **NATV**, **NACV**, **NUTR** and **NUTW** with no cage, it is necessary to shorten the grease replenishing interval.

Further, a roller follower with cage and without seal is not filled up with lubrication grease. When needing a follower with grease-filled cage, feel free to contact **NTN**.

Note that **NTN** offers its unique bearing products prefilled with solid grease: these bearings feature minimized of lubricant leakage.

If low dust-emission characteristics in the atmosphere is necessary, **NTN** will offer bearings prefilled with low dust-emission grease. For more information, contact **NTN** Engineering.

The outer ring outer surface of bearing and the track surface must both be lubricated. Lack of lubrication for these surfaces can lead to premature bearing failure.

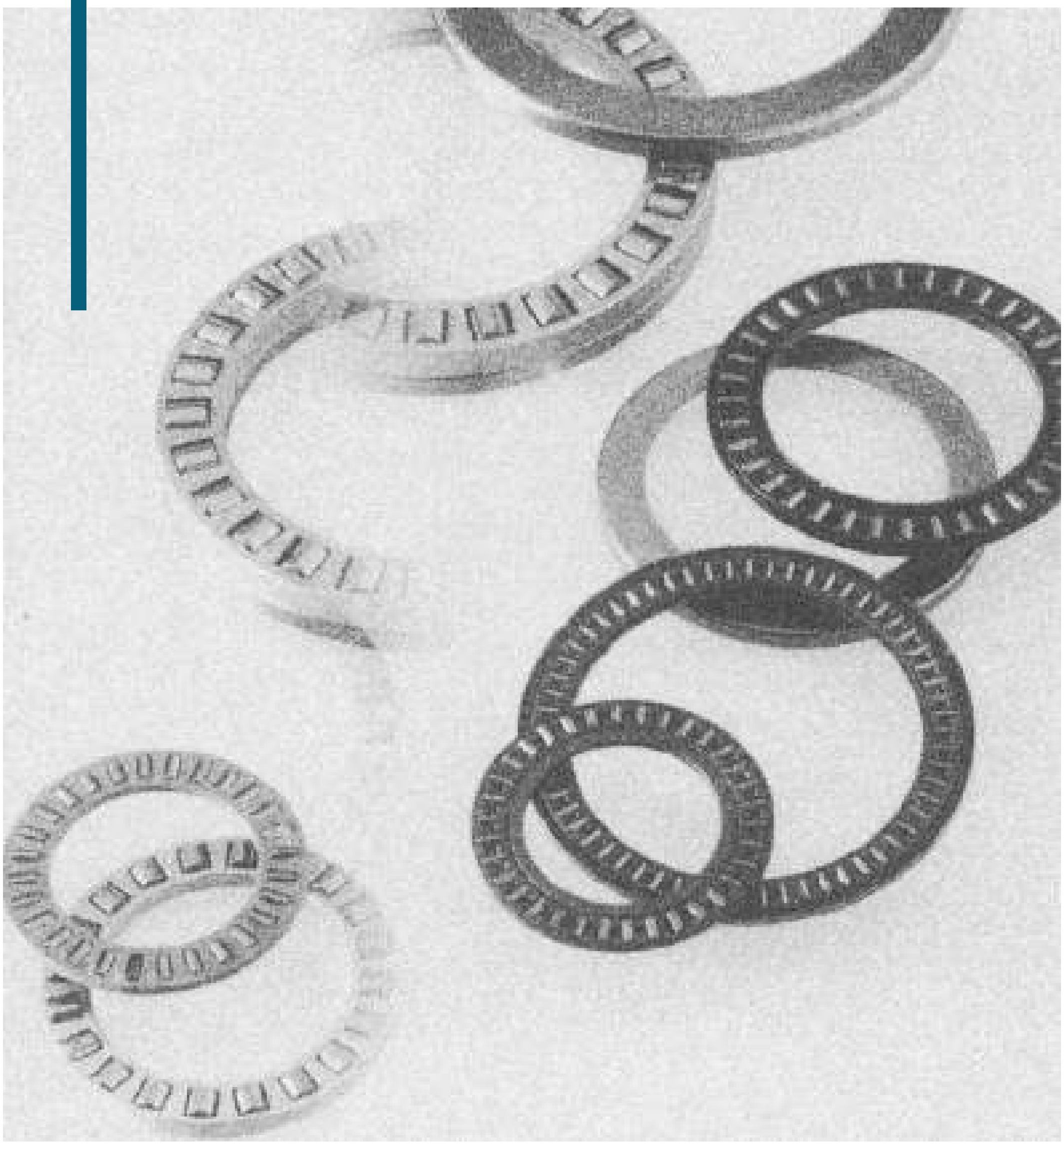
Thrust Roller Bearings



Thrust Roller Bearings

This thrust roller bearing composed of a thrust roller and cage assembly, wherein needle rollers or cylindrical rollers are configured radially in the cage, and a bearing ring of disc form is intended to support one-directional axial load.

In mounting, it is possible to use a shaft or a housing as the direct raceway surface without using the bearing ring, whereby design of a low height and lightweight compact construction is enabled.

This type of thrust roller bearing results in slipping on raceway surface because theoretically it can't roll perfectly, but in most cases it is practically trouble-free and can rotates at comparatively high speed.

Bearing type	Cage type	Applicable shaft diameter (mm)	Composition of bearing number	Bearing number	Remarks
AXK 	Pressed steel cage	φ10—φ120	**AXK 11 04** Bore diameter code Dimension series code Type code	**AXK1104**	The type can be used together with theType AS bearing ring with the lower limit of safety factor S_0 is 3
	High strength brass cage	φ130—φ160			
K811 K812 	Standard type Polyamide resin cage	**Type K811** φ10—φ120 **Type K812** φ30—φ80	**K8 11 10 T2** Suffix Bore diameter code Dimension series code Type code	**K81110T2**	The suffix T2 means that this bearing uses a polyamide resin cage. Therefore, use this bearing at a temperature 120˚C or lower; or at 100˚C or lower for continuous operation. Feel free to contact NTN for the detail of the pressed steel cage. Possible to use in combination with GS and WS bearing rings. K811 conforms to the Dimension Series 11 specified in JIS B 1512. K812 conforms to the Dimension Series 12 specified in JIS B 1512.
	Aluminum alloy cage	**Type K811** φ130—φ160 **Type K812** φ85—φ140			
	Pressed steel cage	φ10—φ90	**[Suffix]** T2: resin cage JW: Pressed steel cage		
K893 	Aluminum alloy cage	φ30—φ110	**K8 93 10** Bore diameter code Dimension series code Type code	**K89310**	K893 conforms to the Dimension Series 93 specified in JIS B 1512.
K874 	Aluminum alloy cage	φ40—φ90	**K8 74 10** Bore diameter code Dimension series code Type code	**K87410**	K893 conforms to the Dimension Series 93 specified in JIS B 1512.

Bearing type		Applicable shaft diameter (mm)	Composition of bearing number	Bearing number	Remarks
811 812 		ϕ10—ϕ160	8 11 10 T2 Suffix Bore diameter code Dimension series code Type code [Suffix] T2: resin cage J: Punched steel plate cage	81110T2	The suffix T2 means that this bearing uses a polyamide resin cage. Therefore, use this bearing at a temperature 120˚C or lower; or at 100˚C or lower for continuous operation. WS and GS bearing rings are used in set. 811 conforms to the Dimension Series 11 specified in JIS B 1512. 812 conforms to the Dimension Series 12 specified in JIS B 1512.
893 		ϕ30—ϕ110	8 93 10 Bore diameter code Dimension series code Type code	89310	WS and GS bearing rings are used in set. 893 conforms to the Dimension Series 93 specified in JIS B 1512.
874 		ϕ40—ϕ90	8 74 10 Bore diameter code Dimension series code Type code	87410	WS and GS bearing rings are used in set. 874 conforms to the Dimension Series 74 specified in JIS B 1512.
AS 	Pressed steel ring	ϕ10—ϕ160	AS 11 04 Bore diameter code Dimension series code Type code	AS1104	Because of its 1mm thick steel plate ring, this thrust bearing needs adequate rigidity and profile accuracy of machine parts adjacent to the bearing. As an individual, on occasion this thrust bearing results in slight camber, but it is flattened when specific thrust load acts thereon, having no problem in practical use. The lower limit of safety factor S_0 is 3.
WS811 WS893 WS812 WS874 	Machined type, for inner ring land riding	ϕ10—ϕ160	WS8 11 04 Bore diameter code Dimension series code Type code	WS81104	Higher rigidity and higher running accuracy than AS bearing ring .

Bearing type	Applicable shaft diameter (mm)	Composition of bearing number	Bearing number	Remarks
GS811 GS893 **GS812 GS874**  Machined type, for outer ring land riding	φ10—φ160	**GS8 11 04** 04: Bore diameter code 11: Dimension series code GS8: Type code	**GS81104**	Higher rigidity and higher running accuracy than AS bearing ring .
ZS (Central washer) 	φ10—φ160	**ZS 15 34** 34: Outside diameter 15: Dimension series code ZS: Type code	**ZS1534**	The central washer is used as an outer ring or inner ring in a double-direction thrust roller bearing. This washer can be used in combination with needle roller and cage thrust assembly AXK, or cylindrical roller and cage thrust assembly K811, or locking ring (outer ring) GS811 for locking the bearing to a housing or locking ring (inner ring) WS811 for locking the bearing to a shaft.
AXA21 	φ10—φ140 (Central washer)	**AXA21 04** 04: Bore diameter code AXA21: Type code	**AXA2104**	This is a double-direction thrust roller bearing that comprises two needle roller and cage thrust assemblies AXK, two housing-side locking rings (outer rings) GS811 and one central ring ZS.
ARA821 	φ10—φ140 (Central washer)	**ARA821 04 T2** T2: Suffix 04: Bore diameter code ARA821: Type code [Suffix] T2: resin cage	**ARA82104T2**	The suffix T2 means that this bearing uses a polyamide molded cage. Therefore, use this bearing at a temperature 120˚C or lower; or at 100˚C or lower for continuous operation. This is a double-direction thrust cylindrical roller bearing that comprises two cylindrical roller and cage thrust assemblies K811, two housing-side locking rings (outer rings) GS811 and one central ring ZS.
AXB21 	φ15—φ160 (Central washer)	**AXB21 04** 04: Bore diameter code AXB21: Type code	**AXB2104**	This is a double-direction thrust needle roller bearing that comprises two needle roller and cage thrust assemblies AXK, two shaft-side locking rings (inner rings) WS811 and one central ring ZS.
ARB821 	φ15—φ160 (Central washer)	**ARB821 04 T2** T2: Suffix 04: Bore diameter code ARB821: Type code [Suffix] T2: resin cage	**ARB82104T2**	The suffix T2 means that this bearing uses a polyamide molded cage. Therefore, use this bearing at a temperature 120˚C or lower; or at 100˚C or lower for continuous operation. This is a double-direction thrust cylindrical roller bearing that comprises two cylindrical roller and cage thrust assemblies K811, two shaft-side locking rings (inner rings) WS811 and one central ring ZS.

Bearing accuracy

The dimensional accuracy, profile accuracy and running accuracy of **Types 811, 812, 893** and **874** thrust cylindrical roller bearings shall be as specified in **Table 4.4** in Sec. **4. "Bearing accuracy"** (page A-28).

The thrust roller and cage assembly **Types AXK, K881, K812, K893** and **K874** are machined to the following dimensional tolerances: E11 (or E12 for bearing marked with T2) for bore diameter (D_{c1}) and c12 for outside diameter (D_c) on **Type AXK**, and a13 for **Types K811, K81, K893** and **K874**.

Raceway surface requirements:

Where the plane portion of a shaft/a housing is used as the direct raceway surface of thrust roller and cage assembly, the raceway surface must meet the requirements specified as a guideline in **Table 1**.

Table 1 Raceway surface requirements (recommended)

Characteristics	Specified requirements
Perpendicularity (Max)	IT5 (IT4)
Surface roughness	0.2a
Surface hardness	HRC58～64
Effective case depth	Refer to Formula (8.1) on page A-40.

Reference : The parenthesized value shall be applied for high running accuracy.

Cage guiding

To be able to center a running thrust roller and cage assembly (Type **AXK, K811, K812, K893 K874**), it is necessary to guide it on its bore (shaft side) or outside surface (housing side).

In general, the bore-side guide of low relative speed against the cage is mostly used. It should be used particularly for high speed running. The dimensional tolerances for shaft and housing, when the cage is guided thereby, shall be h8 for shaft diameter (bore guide) and H9 for housing bore diameter (outer surface guide) respectively, which of the guide surface shall be fine-finished by grinding.

Bearing fit in bearing ring

Table 2 shows the tolerances for fitting of the thrust bearing rings (**AS**, **WS** and **GS**) on shaft or in housing.

Table 2 Bearing ring fit in shaft and housing (recommended)

Bearing ring		Shaft	Housing
Type AS	Locking to shaft	h10	Clearance to housing
	Locking to housing	Clearance to shaft	H11
Type WS (inner ring)		h6	—
Type GS (outer ring)		—	H7
Type ZS (central ring)	Locking to shaft	h6	—
	Locking to housing	—	H7

Mounting related dimensions

The mounting dimensions for bearing ring **Types WS, GS** and **ZS** relative to a shaft or housing are listed in the relevant dimension table.

The fitting surface of **AS** bearing ring must be flat and have the rigidity sufficient to support thrust load throughout its entire surface.

The bearing ring has to be installed in correct orientation so that its raceway surface is seated onto the rolling elements. (As shown in the diagram in the relevant dimension table, the narrower chamfering on the bearing ring marks the raceway surface.)

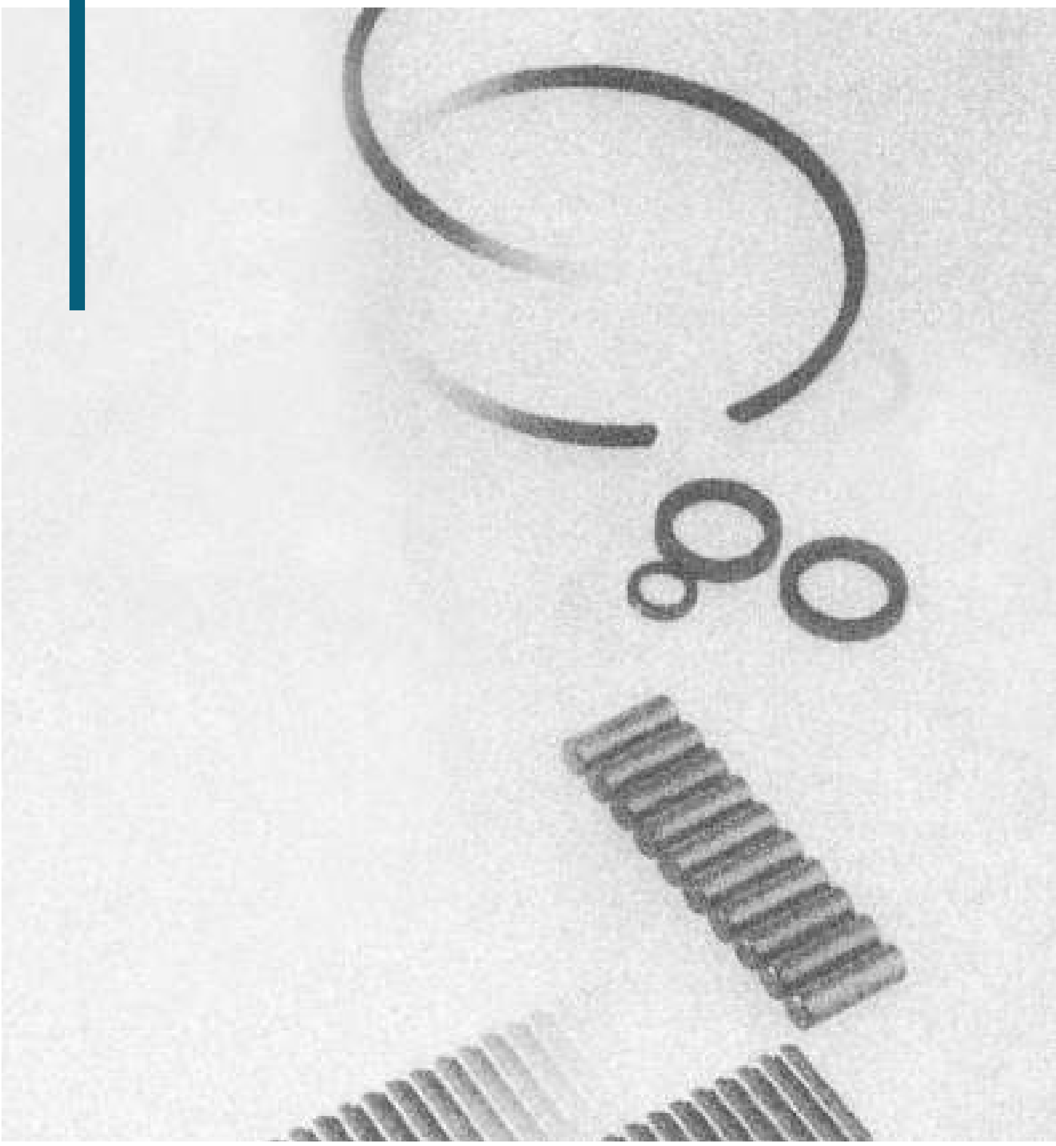
COMPONENTS
Needle Rollers/Snap Rings/Seals



Needle Rollers

NTN needle rollers are all made of high carbon chrome bearing steel, fine-finished by grinding and polishing after heat-treated, and the hardness thereof ranges from HRC60 to 65. These needle rollers are supplied as not only rolling element but also pin and shaft individuals.

End face profile of needle roller

F-type needle roller bearing with flat end face is standard type, while A-type with round end face is semi-standard type. In addition to these two types, another needle roller type (nominal number with (suffix E) capable of damping edge load is also available. Feel free to contact **NTN** for the detail thereof.

Table 1 End face profile

Type	Name	Profile
F	Flat	
A	Round	

Composition of needle roller number

The needle roller number comprises type code (end face profile), dimension code [diameter (D_w)×length (L_w)] and a suffix.

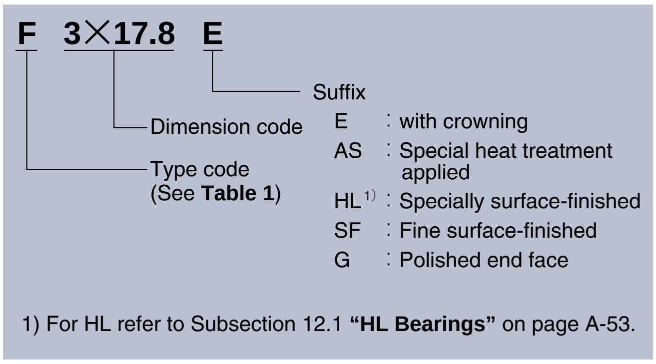


Fig. 1

Needle roller tolerances

The **NTN** needle rollers are manufactured per the dimensional accuracy and profile accuracy specified in JIS B 1506 "Rollers for roller bearings". (Refer to **Table 2** in this page.)

Table 2 Needle roller tolerances Unit: μm

Characteristics	Tolerance and allowable value
Tolerance for mean value of diameter D_w	0～−10
Mutual deviation of diameter D_w	2
Roundness of diameter D_w, Diameter variation in a single radial plane	1.0 (L_w/D_w≦6) 1.5 (L_w/D_w>6)
Tolerance for length L_w	h13
Accuracy class	Class-2

The needle rollers are delivered contained in same package after the mutual deviation of diameter D_w was assorted to 2μm and less. Before being delivered, the needle rollers are identified by label colors such as red, dark blue, blue, etc. according to the respective dimensional tolerances.

Further, mixed use of needle rollers contained in packages of different label colors is prohibited.

Table 3 Discrimination of needle rollers

Label color	Dimensional tolerance range μm	Discrimination
Red Dark blue Blue Black White	0～−2 −1～−3 −2～−4 −3～−5 −4～−6	Standard
Gray Green Brown Yellow	−5～−7 −6～−8 −7～−9 −8～−10	Semi-standard

Application of needle rollers

When configuring a full complement needle roller bearing using standard needle rollers, the shaft diameter (d), housing bore diameter (D), circumferential clearance (ΔC) and radial internal clearance (Δr) can be determined based on the needle roller diameter (D_w) and number of rollers (Z) by using the formula below (refer to **Fig. 2**).

Determine the minimum value of circumferential clearance (ΔC) using **formula (1)**. The radial internal clearance (Δr) of an intended needle roller bearing can be determined based on the shaft diameter and projected bearing operating conditions by referring to **Table 5.1** in Sec. **5.1 "Bearing radial internal clearance"** (page A-30). Generally, any full complement roller bearing needs a greater radial internal clearance compared with a needle roller and cage assembly.

$$\Delta C = (0.005 \sim 0.020) \times Z \text{ mm (minimum value)} \quad \textbf{(1)}$$

Then, determine the minimum value of housing bore diameter (D) and the maximum value of shaft diameter (d) using the **formulas (2)** and **(3)**.

$$D = \frac{1}{\sin\left(\frac{\pi}{Z}\right)} \cdot \left(D_w + \frac{\Delta C}{Z}\right) + D_w \text{ mm (minimum value)} \quad \cdots\cdots\cdots\cdots\textbf{(2)}$$

$$d = D - 2D_w - \Delta r \text{ mm (maximum value)} \cdots\cdots\cdots\textbf{(3)}$$

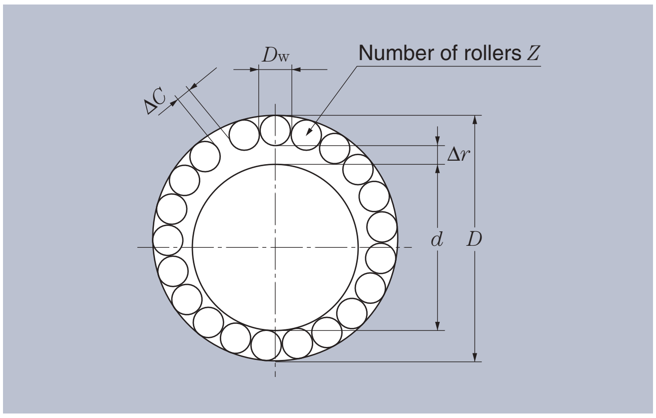

Fig. 2

The maximum value of housing bore diameter (D) required to retain needle rollers in a housing by a keystone can be determined from the minimum diameter value ($D_{w\,min}$) of the roller and the number of rollers using **formula (4)**. The coefficient K to be used in that time is as shown in **Table 4**.

$$D = K \cdot D_{w\,min} \text{ mm (max.)} \cdots\cdots\cdots\cdots\cdots\cdots\textbf{(4)}$$

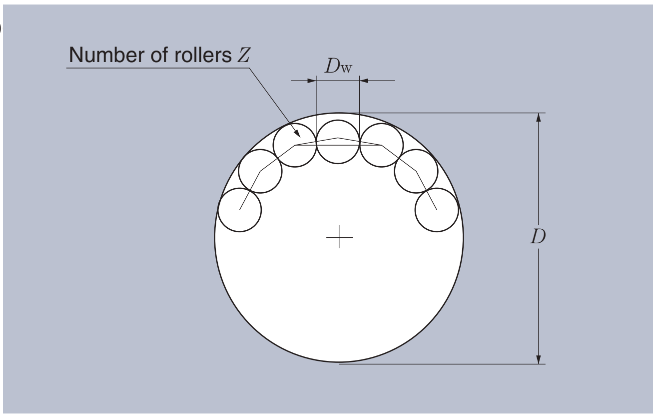

Fig. 3

Snap Rings

These snap rings are used exclusively for fixing or guiding a needle roller bearing ring or cage in axial direction. Furthermore, these snap rings have the profile identical to C-type concentric snap ring specified in JIS B 2806 and, in addition, snap rings with smaller section height (b) and also available in smaller dimension range are manufactured according to application of needle roller bearings. These snap rings are manufactured using hard steel wire rod and, after manufactured, chemical conversion treatment is applied to the surface thereof.

Types of snap ring

Two types of snap ring are available; one is **Type WR** designed for application to shaft and another is **Type BR** for application to bearing housing.

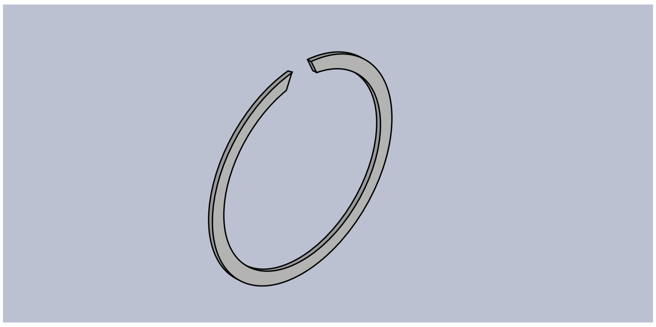

Fig. 1 WR snap ring

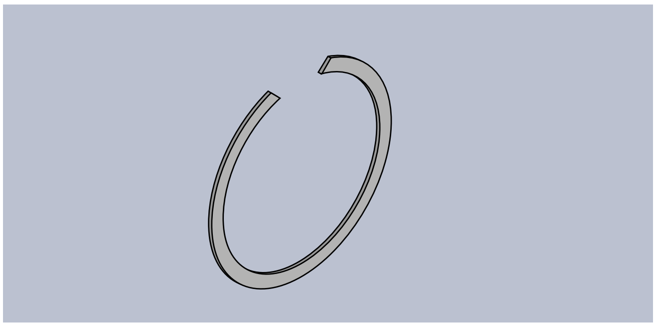

Fig. 2 BR snap ring

Table 1 Cut section angle of snap ring (α)

Type	Nominal number	Cut section angle(α)
Type WR	WR4, WR5	40°
	Type WR6 up to	60°
Type BR	All nominal numbers	90°

Composition of snap ring number

The snap ring number is composed of type code (**WR** or **BR**) and dimension code. The dimension code represents applicable shaft diameter in **Type WR** and applicable housing bore diameter in **Type BR**.

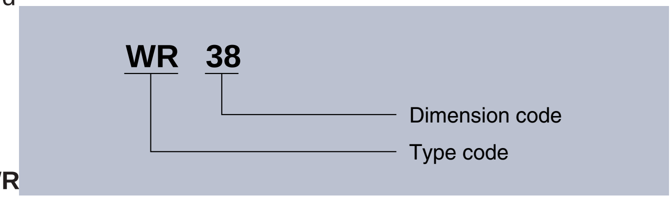

Fig. 3

Allowable running speed

The allowable running speed for **Type WR** for shaft application is as described in applicable Dimensions Table. This means the running speed when snap ring begins to get loose with opening of its cut ends.

Mounting relation

It is recommended to insert a spacer between snap rin and cage for guiding the cage in axial direction (Refer to **Fig. 4**.). On occasion, snap ring is difficult to remove, bu limited to a portion in which a pull-out tool can not be inserted easily. In such a case, consider the cross-sectional height of the needle roller bearing in question, and then judge whether or not an ordinary retaining ring (JIS B 2804 “Retaining rings-C type”) can be used.

Seals

Seals

These are the special-purposed seals for needle roller bearings whose cross sectional height is designed so small as to match applicable needle roller bearings. These contact seals are made of synthetic rubber reinforced with steel plate, being then used in operating temperature range of -25 to +120˚C and, under continuous running, at 100˚C and less. Further, feel free to contact **NTN** for the use of these seals under special operating condition, e.g. operating temperature of over 120˚C.

Types of seal

Two different seal types are available; one is **Type G** with one lip and another is **Type GD** with two lips. In addition to these two, sliding rubber seals (**LEG**, **LEGD**), wherein lubrication property was assigned to a rubber material fulfilling low torque under an non-lubrication environment, are also manufactured. Feel free to contact **NTN** for the detail of these seal types.

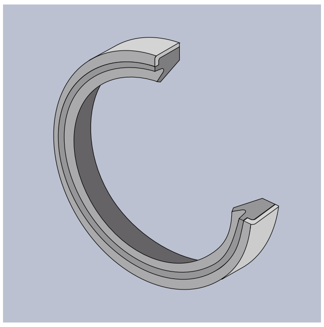

Fig. 1 Type G (LEG)

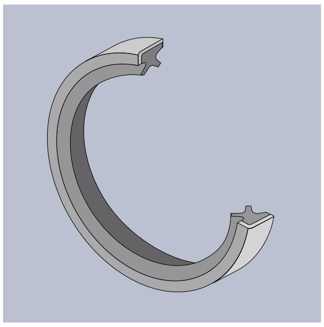

Fig. 2 Type GD (LEGD)

Where seal contact surface and lubricating condition are good, **Type G** with one lip can be used up to 10m/s maximum at peripheral speed and **Type GD** with two lips used up to 6m/s maximum.

This seal is intended to hold grease and to prevent dust invasion from outside. It has no function to hold lubrication oil, etc. unlike oil seal.

Composition of seal number

The seal number is composed of type code (G, GD) and dimension code (bore dia.×outer dia.×width).

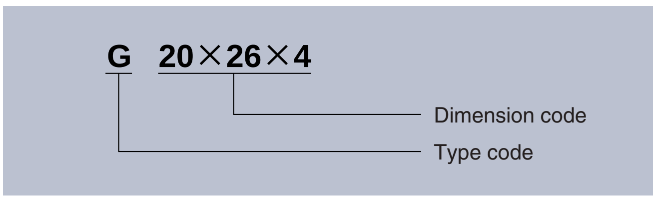

Fig. 3

Fitting relations

The seal contact surface must be finished by grinding, after hardened, to get its good sealing performance. In addition, harmful flaw and indent are not allowed to exist on the seal contact surface. Where the inner ring raceway surface is used as seal contact surface, a wide inner ring must be used.

When fitting a seal in a bearing, it is desirable to taper the shaft end face or the housing end face so as to protect the seal lip and outer surface from damaging, as illustrated in **Fig. 4**. Where shaft end is not tapered or chamfered (rounded), it is recommended to a fitting jig as illustrated in **Fig.5**. Regarding the seal to housing interference, a adequate interference can be got in the usual housing tolerance range of G7 toR7.

Furthermore, it is recommended to apply pre-coat of a lubricant to the seal lip before fitting seals G and GD, for better lubrication. Further, when fitting a seal and inserting it through a shaft, take good care to protect its lip from deforming.

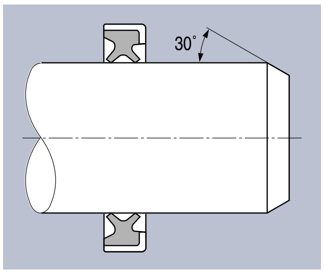

Fig. 4

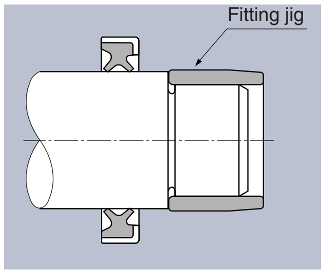

Fig. 5

Seal application examples

Figs.6 to **8** illustrate design examples using these seals.

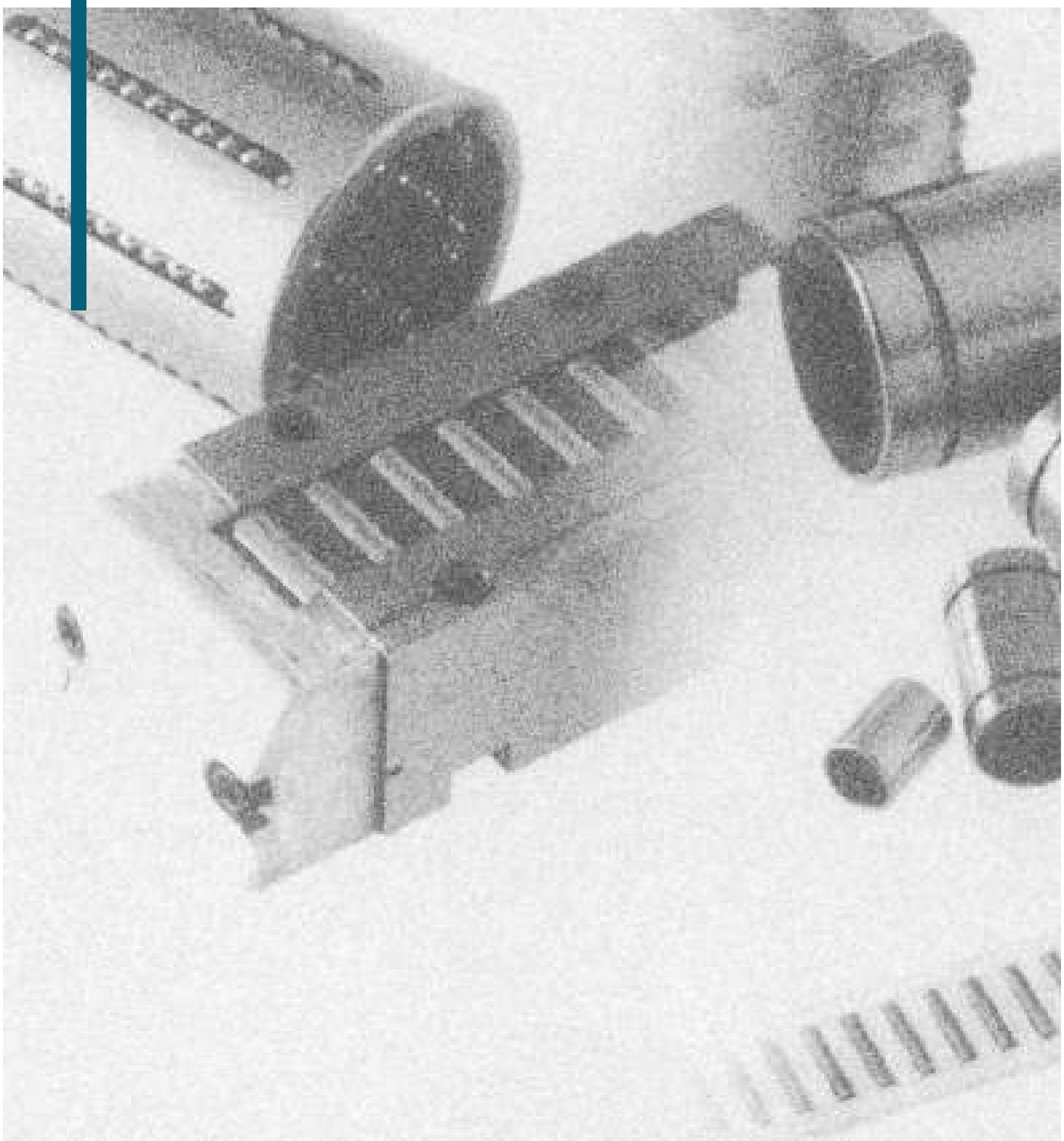
LINEAR BEARINGS

LINEAR BALL BEARINGS:
Drawn Cup, Solid, Stroke, Linear Flat Roller, and Linear Roller Bearing Types



Linear Ball Bearings

Type		Applicable shaft diameter (mm)	Composition of bearing number
KH 	This type is composed of an outer ring, steel balls and a cage and the outer ring is cylindrical similarly to that of Type KLM and drawn from a steel plate by precision deep drawing, then enabling to design a compact bearing construction of low section and lightweight. This type also ensures precise and smooth infinite linear motion similarly to other types.	φ6—φ50 With seal φ10—φ50	**KH 20 30 LL/3AS** Suffix LL: Seal 3AS: Grease code Width Roller set bore diameter Type code
KLM 	This type composed of an outer ring, steel balls and a cage is a cylindrical bearing for the most universal applications, which ensures precise and smooth infinite linear motion due to its outer ring of high rigidity.	φ3—φ40	**KLM 06 LL/3AS** Suffix LL: Seal 3AS: Grease code Roller set bore diameter Type code
KLM··S 	his type is composed of an outer ring, steel balls and a cage. And both of the outer ring and the cage have an axial slit, as illustrated, so as to enable to shrink the inscribed circle diameter of the cage by pressing the outer ring in radial direction from the housing and to thereby adjust radial clearance from shaft. Thus, this type also ensures precise and smooth infinite linear motion.	φ16—φ40	**KLM 30 S** Suffix S: Clearance-adjustable Roller set bore diameter Type code
KLM··P 	This type is composed of an outer ring, steel balls and a cage. And the outer ring and the cage are of arc sectional shape, from which one row of balls (equivalent to 50˚ to 60˚ degree spacing) is removed. Thus, the arc cross-sectional ring and cage with 50˚ to 60˚ degree opening allows the bearing assy to pass through a shaft support truss or a shaft support stand on midway of the shaft stroke. This type also ensures precise and smooth infinite linear motion, similarly to other types. The bearing radial clearance can be also adjusted.	φ16—φ40	**KLM 30 P LL/3AS** Suffix P: Open configuration LL: Seal 3AS: Grease code Roller set bore diameter Type code

Type		Applicable shaft diameter (mm)	Composition of bearing number
KD 	This type composed of an outer ring, steel balls and a cage is a cylindrical bearing for the most universal applications, which ensures precise and smooth infinite linear motion due to its outer ring of high rigidity.	Shaft diameter φ10—φ80	**KD 20 32 45 LL/3AS** Suffix LL: Seal 3AS: Grease Width Outer diameter Roller set bore diameter Type code
FF **FF··ZW** 	This type composed of a cage and needle rollers ensures smooth reciprocating motion of less friction actor by being inserted between two planes in relative position. The cage made of polyamide resin is provided with grooved joint at its both ends so several cages can be jointed together into one unit.	Roller diameter φ2—φ3.5	**FF 25 18 ZW** Suffix ZW: Double row Width Roller diameter ×10 Type code
BF（RF） 	This type composed of a cage and needle rollers ensures smooth reciprocating motion of less friction factor by being inserted between two planes in relative position. Press-formed steel plate cage (BF) and polyamde resin cage (RF) are selectively available. However, in the case of this bearing type several bearings can't not be jointed together into one unit.	Roller diameter φ3—φ7	**BF 30 20 / 1000** Cage overall length Width Roller diameter ×10 Type code
RLM 	This type is composed of a track frame, a separator and rollers. This type has the function enabling cylindrical rollers to circulate within the track frame and ensures infinite linear motion on a plane.	Section height 16—38	**RLM 26 × 86** Bearing overall length Section height Type code

Components	Infinite motion	Finite motion	Rotating motion	Remarks
Roller set bore diameter: φ20 Outer diameter: f32 Width: 45 Seal: Double-side seal Grease: Prefilled	×	○	○	To avoid deterioration of seal and grease, use a bearing in a temperature range of -20 to 120 C. For continuous machine operation, limit the maximum permissible operating temperature to 100˚C.
Roller diameter: φ2.5 Width: 18 ZW: Double-row type Number of rows: Two	○	○	×	Due to its resin cage, this bearing shall be used at allowable temperature 90˚C and, under continuous running, at 80˚C and less. The double-row type has an elastic joint on the cage center so double rows of flat rollers can be bent to any optional angle along the elastic joint by heating them in oil of 70 to 90˚C. By cooling down the double-row rollers with the bent angle held unchanged for several seconds after having bent them to any optional angle, the bent shape of the double rows can be held unchanged so that the double-row rollers can be mounted on a V-shaped surface as illustrated.
Roller diameter: φ3 Width: 20 Cage length: 1000	○	○	×	Where the resin cage RF is used, the bearing shall be used at allowable temperature 90˚C and, under continuous running, at 80˚C and less. The standard length of the bearing unit with BF cage is 1000 mm. The standard length of the bearing unit with RF cage is 705 mm. Two or more bearings of this type can't be jointed with each other, but it can be supplied at any desired length on request.
Section height: 26 Bearing overall length: 86	○	○	×	

Linear Ball Bearings, Drawn Cup and Solid Types

Four to nine rows of balls are configured equally in the outer ring (outer cylinder). The ball rows circulate in axial direction while being guided by the cage. Thus, these bearing types move infinitely on a shaft in axial direction. However, these bearing types can't rotate.

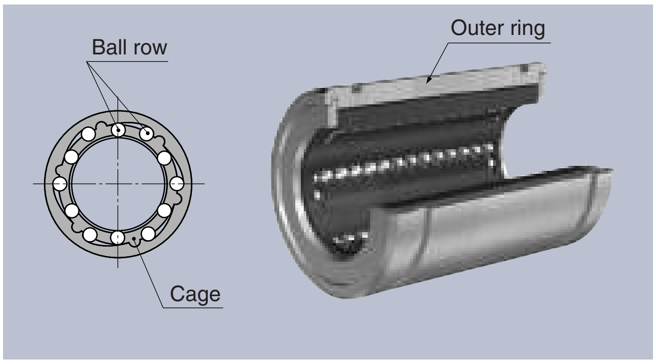

Fig. 1

Dimensional accuracy

Because of its thin-walled outer ring, the **Type KH** (drawn cup type) unavoidably develops certain degree of deformation in various manufacturing steps, in particular in the heat treatment process. Nevertheless, this bearing type has been designed so that when press-fitted into a housing of accurate dimensions, its deformation is corrected and it can restore its original accuracy to fully develop its design functions. For a method for determining dimensional accuracy of this bearing, contact **NTN** Engineering for technical assistance.

The dimensional accuracies in boundary dimensions, ball set bore diameter (F_w), outside diameter (D) and width (C) of the **Type KH** (**KLM** solid type) are listed in the relevant dimension table. Upon request, **NTN** will supply linear ball bearing products for higher accuracy. For details, contact **NTN** Engineering.

Bearing fit

By employing a shaft or housing featuring dimensional tolerance in **Table 1** in this page, an appropriate radial internal clearance can be provided in the installed bearing. When a further smaller radial internal clearance is needed, achieve selective fit to obtain an intended radial internal clearance by selecting a relevant bearing-shaft or bearing-housing combination.

Table 1 Bearing fit

Type	Shaft	Housing
series HK Drawn-cup type	h6 (j5)	H7 (H6) - steel series - K7 (K6) - light metal alloy series -
series KLM Solid type	g6 (g5)	H7 (H6)

Note) The parenthesized data is applied to shaft/housing subjected to higher accuracy or of vertical construction.

Shaft and housing requirements

Any shaft /housing on/in which these bearing types are fitted must meet the requirements specified in **Table 2**.

Table 2 Shaft and housing requirements (recommended)

Characteristics	Shaft	Housing
Roundness (max)	IT3	IT4
Cylindricity (max)	IT2	IT4
Surface roughness (max.)	0.4a	1.6a
Surface hardness	HRC58~64	—
Case depth (min)	0.4mm	—

How to mount

The Type KH (drawn cup) bearing is press-fitted into the housing in interference fit mode: therefore this type bearing does not need axial positioning with a means such as a snap ring. For press-fitting, force the marking side on the outer ring with a mandrel illustrated in **Fig.**

The **Type KLM** (solid type) cannot be locked to the housing by interference alone. This type of bearing need to be axially located with a snap ring.

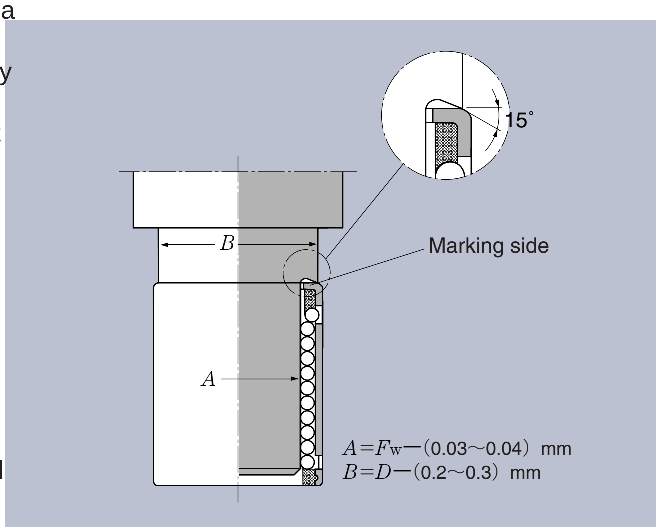

Fig. 2 Series KH

Accessories

Shafts, shaft support stands and housings exclusive for **NTN** linear ball bearings are also offerable. Feel free to contact **NTN** for the detailed information.

Linear Ball Bearings, Stroke Type

The bearing cage with multiple ball rows (several balls per row) configured circumferentially therein can move within the outer ring in both circumferential and axial directions. Thus, this bearing type can rotate and reciprocate (but at a limited stroke) on a shaft.

Bearing construction

Maximum available length of the reciprocal stroke is two times as long as the stroke at which the cage ca reciprocate within the outer ring. The outer ring is provided at its both ends with a snap ring acting as a stopper and a wave spring is provided between the sna ring and the cage to damp a shock acting on the cag well as to prevent wear of the cage.

In addition to the standard type, a special type with synthetic rubber seal (Tail code: **LL**) on the both ends of its outer ring is also available.

Dimensional accuracy of Bearing

Table 1 the bearing tolerance.

Table 1 Dimensional accuracy

Characteristics	Dimensional tolerance
Ball inscribed circle diameter (F_w) Outer ring outer diameter (D)	F6 h5

Bearing fit and radial internal clearance

Linear ball bearings need to be used with minimum possible radial internal clearance. In particular, when a linear bearing is used on a vertical shaft or higher accuracy is needed, it is desirable to combine a bearin with a selected shaft and use the bearing-shaft combination with a radial internal clearance in a range 0 to -5 mm (guideline).

Table 2 shows the bearing fits on shaft and in housin

Table 2 Bearing fits (recommended)

Operating conditions	Shaft	Housing
Usual operating conditions	k5 (m5)	H6 (H7)
Vertical shaft and high accuracy applications	n5 (p5)❶	J6 (J7)

Shaft and housing requirements

Table 3 specifies the requirements for shaft and housing which of the outer surfaces are used as the d raceway.

Table 3 Shaft and housing requirements (recommended)

Characteristics	Shaft	Housing
Roundness (max)	IT2	IT4
Cylindricality (max)	IT2	IT4
Surface roughness (max)	0.2a	1.6a
Surface hardness	HRC58～64	–
Hardened layer depth (min)	0.4mm	–

How to mount

This bearing type can't be fixed perfectly to a housin with interference only and, therefore, it is fixed in axial direction using a snap ring. (Refer to **Fig. 1**)

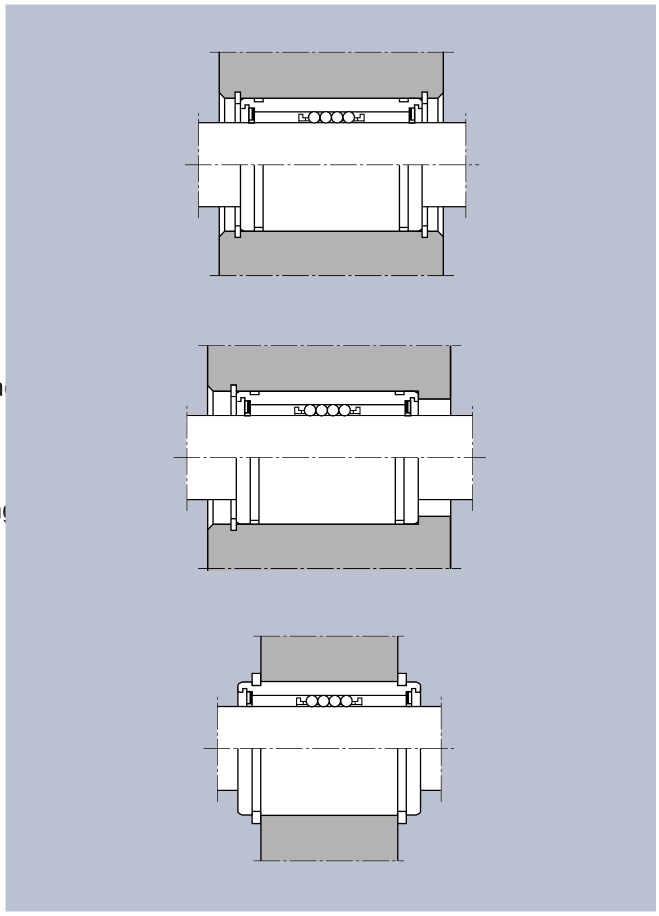

Fig. 1 Axial fixing of bearing

For adjusting the cage so it locates at the outer ring center after a shaft was mounted, push the cage in the arrow direction in **Fig. 2** by inserting the shaft into the outer ring that was press-fitted in the housing. (**Fig. 2**)
In this condition, insert slowly the shaft up to the center point of the reciprocating stroke and, thereafter, further push-in the shaft by 1/2 of the stroke. (**Fig. 3**) Then, return the shaft by 1/2 of the stroke to thereby locate the cage at the outer ring center and the shaft at the center point of the reciprocating stroke. (**Fig. 4**)

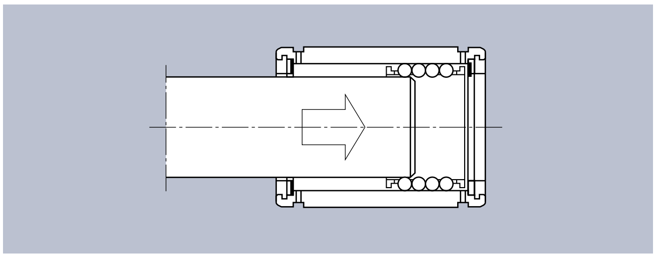

Fig. 2

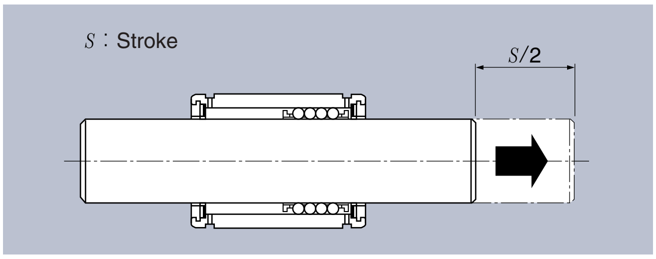

Fig. 3

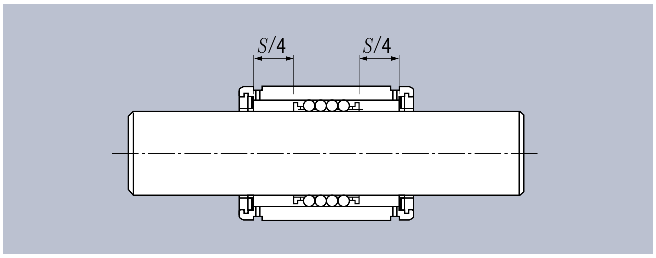

Fig. 4

The outer ring must be press-fitted so its grease feed hole locates at load non-acting side.
Where moment load acts on a bearing due to use of a vertical shaft, the load could act on the grease feed hole. Caution it.

Note 1) The tolerance for dimension C is -0, -0.120 mm against $F_w \leq 50$ mm and 0, -0.150 mm against $F_w > 50$ mm.

Linear Flat Rollers

Linear Flat Rollers

This bearing type composed of a needle roller and flat cage assembly (needle rollers are configured in the flat cage) ensures smooth reciprocating motion with less friction coefficient.

Types

For **Type FF**, the polyamide resin cage has a dovetail joint groove on its both ends so that several cages can be jointed together into one unit.

For **Type FF-ZW**, two rows of needle rollers are configured in the cage and the cage has an elastic joint on its center so as to enable to bend two rows of flat rollers to any optional angle at the elastic joint by heating them in oil of 70 to 90˚C. The two roller rows bent to optional angle can hold the bent shape unchanged, even under normal operating temperature, by being cooled down for several seconds, with the bending angle held unchanged.

For **Type BF**, the cage is press-formed from steel plate and the standard length of the bearing unit is 1000 mm.

For **Type RF**, the cage is of polyamide resin and the standard length of the bearing unit is 705 mm. The both are unavailable for cage to cage inter-jointing, but a bearing unit of any desired length is offerable upon request. Feel free to contact **NTN** for the detailed information.

Needle roller tolerance

The needle rollers contained in the flat roller cage are manufactured within the dimensional tolerance range of 0 to -2 μm against the nominal diameter (D_w).

Raceway surface requirements

Table 1 shows the requirements for raceway surface applied to the linear flat roller bearings.

Table 1 Raceway surface requirements (recommended)

Characteristics	Tolerance
Surface roughness (max)	0.2a
Surface hardness ❶	HRC58～64
Effective hardened layer depth (min)	0.4mm
Mounting accuracy (max)❷	0.1 mm per 1000 mm

❶ Where raceway surface hardening not allowed, a quenched spring plate may be used.
❷ Mounting accuracy is expressed with an inclination value in **Fig. 1.**

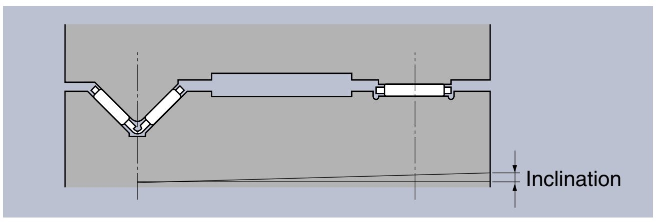

Fig. 1

How to mount

Theoretically the linear flat roller bearing moves by 1/2 of table moving stroke in same direction as the table moving direction. The relationship of bed length (L) - stroke (S) - cage length (L_1) can be expressed in **formula (1).** (**Fig. 2**)

$$L=S/2+L_1 \quad \cdots\cdots (1)$$

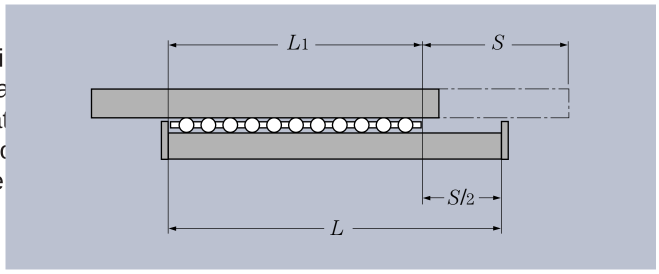

Fig. 2

The linear flat roller bearing results in moving deviation due to profile deviation of raceway surface, uneven load or vibration. Therefore, the table or the bed must be equipped with a stopper at its end portion to prevent over run of the flat roller bearing. (**Fig. 5**)

Figs. 3 and **4** illustrate application examples of the linear flat roller bearing unit.

If a separate raceway surface having undergone heat treatment and grinding is installed to a machine main body, be careful to avoid deformation of the bearing that can result from tightening.

7	35	1 000	30	11	10.5	185 000	445 000	18 900	45 500	**BF7035/1000**	$35.5^{+0.1}_{0}$	$6.7^{0}_{-0.2}$	0.110

Note 1) The dimensional tolerance for needle roller diameter is 0 to -2 μm.
2) The standard length of L_1 the cage shall be 1000 mm for Type BF and 705 mm for Type RF.
Where special cage length is required, the nominal bearing number is followed by the numerical length value as exemplified below.
Ex. Where L_1= 500 mm is required for **BF3020**, **BF302/500**
3) The listed basic load ratings are subject to use of 10 flat rollers. Calculate the basic load ratings for any optional cage length L_1 by the following formula.
$C = f^{7/9} \cdot C_r$
$C_0 = f \cdot C_{0r}$
Herein, f=0.1 (L_1+l-2a) / l
4) The listed weights are subject to L_1=1000 mm.

Remarks: For **Type BF**
1. On occasion, the length of an ordered unit could be shorter by dimension l than shown in each Dimensions Table because the roller and cage assy is cut at the minimum unit of each pocket so as to match the required length.
2. Where this bearing unit is used frequently at various lengths, it is more economical to cut the standard bearing of 1000 mm each desired length at your side.

Linear Roller Bearings

This roller bearing with cylindrical rollers having the function capable of circulating within the raceway block ensures smooth infinite linear motion on a flat surface. The cylindrical rollers are retained and guided by the cage and the ribs of the raceway block.

The cage is of such a construction as not allow adjacent rollers to contact with one another. Hence, the friction coefficient is low.

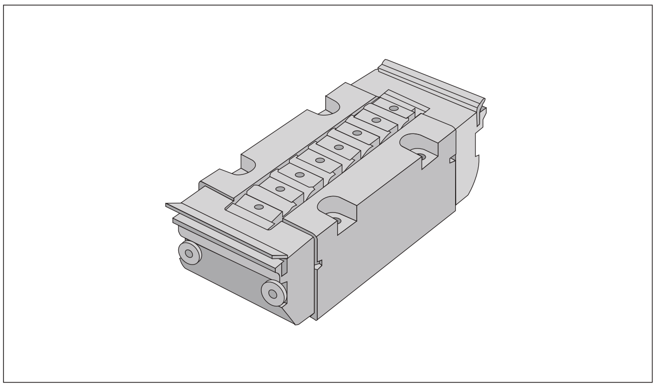

Fig. 1

Bearing accuracy

All the linear roller bearings are manufactured within the dimensional tolerance range of 0 to -2.5μm for bearing height (H). And these bearings are delivered classified into 5-stepped tolerance classes. (See **Table 1**)

Table 1 Classification of bearing height H accuracy class

Unit : μm

Class code	Tolerance for height (H)
1H	0～－ 5
2H	－ 5～－10
3H	－10～－15
4H	－15～－20
5H	－20～－25

Requirements and tolerances for raceway surface and mounting surface

Table 2 shows the requirements and tolerances for the raceway surface, on which linear roller bearing rolls, and the bearing mounting surface. Where adhesion of a hard foreign matter to the raceway surface is forecast, the raceway surface must be protected with a proper protective cover.

The reference surface for mounting is the back face and opposite face to **NTN** mark.

Table 2 Requirements for raceway surface and mounting surface (recommended)

Characteristics	Allowable value or tolerance range
Raceway surface roughness (max)	0.2a
Raceway surface hardness	HRC58～64
Effective hardened layer depth of raceway surface (min)	as described in applicable Dimensions Table
Parallelism of mounting surface	
Δx (See **Fig. 2**)	0.05 mm per 100 mm
Δy (See **Fig. 3**)	0.01 mm per 100 mm

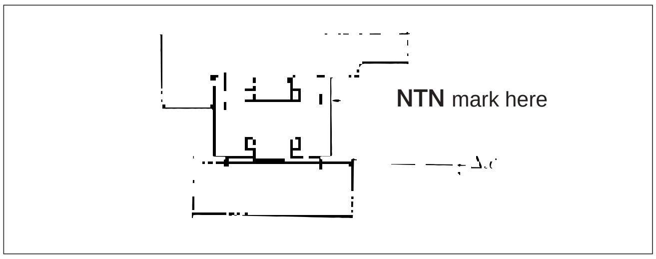

Fig. 2

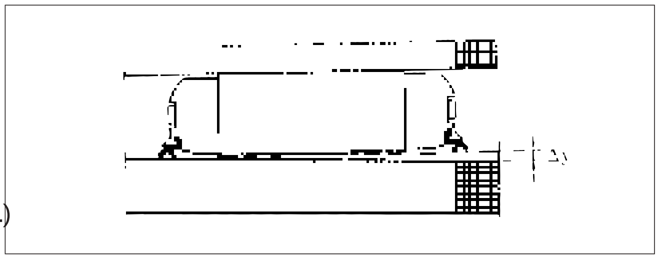

Fig. 3

How to mount

Fix linear roller bearing using the tapped holes which are provided on the mounting reference surface. (See **Fig. 4**)

If a plurality of bearing units are installed on a same plane, select the units that belong to a same bearing height H dimensional accuracy class (**Table 1**) so that t load is uniformly distributed onto them.

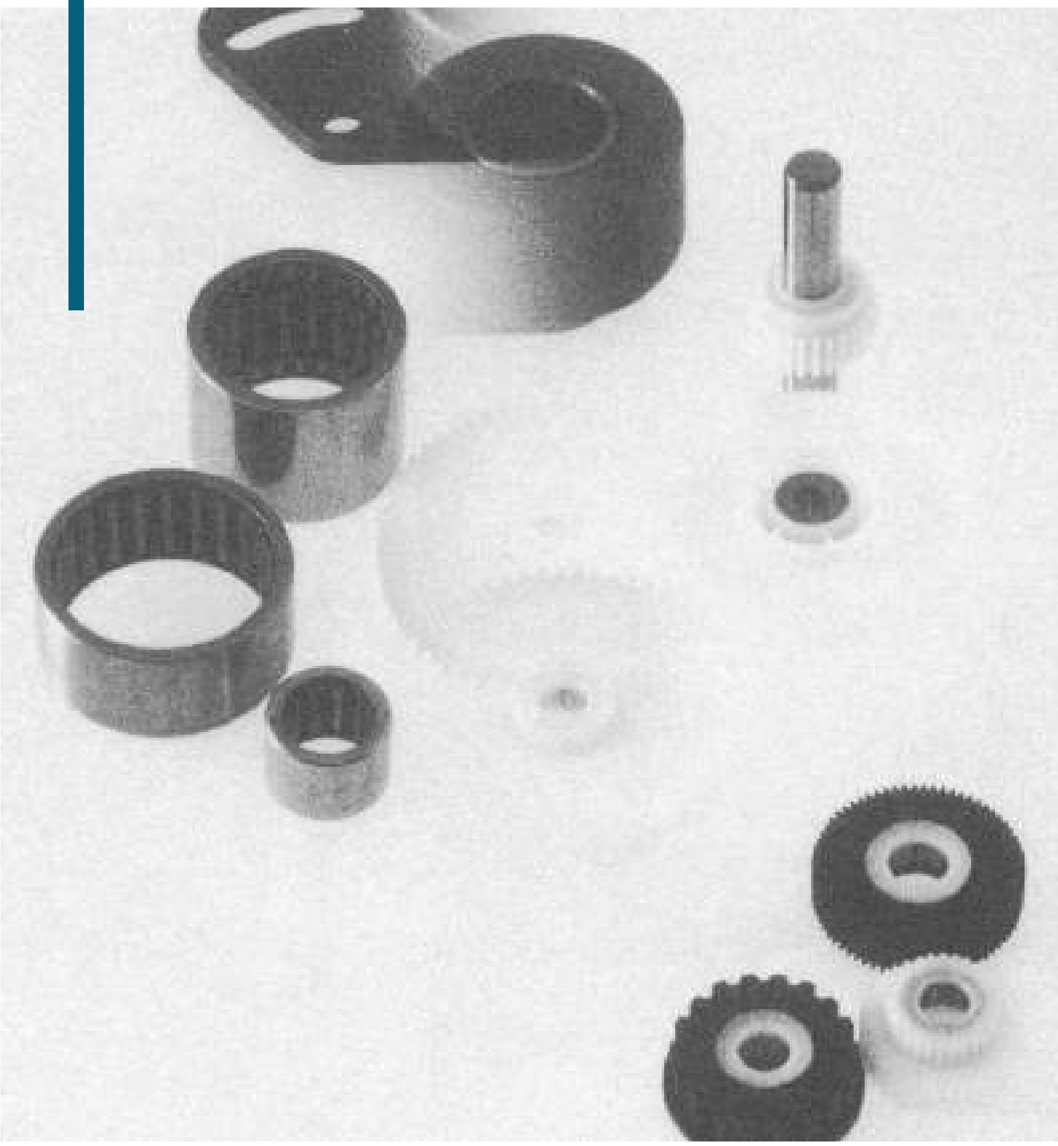
One-way Clutches
Tension Pulleys,
Bottom Roller Bearings



One-way Clutches

This is a compact and roller type one-way clutch whi formed a cam face on its outer ring. (Available shaft diameter range: 6 to 35 mm) When the outer ring be to turn in the counterclockwise direction (direction marke on the outer ring width surface) relative to the shaft, th force of spring causes the rollers to advance to the engagement positions on the outer ring cam face, therel the wedge action taking place between the outer ring c face and the shaft drives the shaft. (See **Fig. 1**) When the outer ring rotates clockwise against the shaft, the shaft rotates counterclockwise relatively to the outer ring and, as the result, the rollers get away from the outer ring cam face and simultaneously the outer ring idles against the shaft. (See **Fig. 2**)

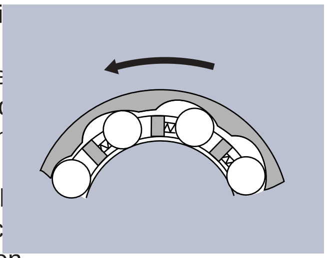


Fig. 1
One-way clutch in engagement

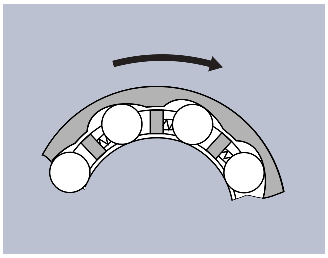

Fig. 2
One-way clutch in idling

Type	Applied shaft diameter (mm)	Composition of nominal clutch number	Remarks
Type HF 	φ6—φ35	HF 10 12 — Width; Bore diameter; Type code	One-way clutch HF composed of an outer ring drawn from a thin steel plate by precision drawing has the clutching function only. **In order for a oneway clutch to be able to carry a radial load and smoothly rotate, its both ends each need to be supported by a radial load carrying bearing.**
Type HFL 	φ8—φ35	HFL 10 22 — Width; Bore diameter; Type code	One-way clutch HFL has an outer ring drawn from thin steel plate by precision drawing, a clutching function, and an integral needle roller and cage assembly capable of supporting radial load at its both ends respectively. Thus, this HFL can function as clutch and, in addition, support radial load.

Both of Type HF and HFL use a polyamide resin cage and press the needle rollers to a wedge, which is formed between the outer ring cam face and the shaft, by action of a plate spring supported with the cage.

Clutch fit

Table 1 shows the one-way clutch fits on shaft and in housing. Both of Type HF and HFL are only press-fitted in a housing, needing no axial fixing by use of a snap ring, etc.

However, due to the outer ring drawn from thin steel by precision drawing, the performance of the both is directly affected by the dimensional and profile deviations of the shaft/housing. To avoid such an inverse affect, shaft and housing accuracy must be controlled with good care. Any housing is required to have the wall thickness of a specified value or more. **Table 2** shows the recommended value.

Table 1 Clutch fits (recommended)

Type	Shaft	Housing	
		Iron series	Light metal alloy
HF HFL	h5 (h6)	N6 (N7)	R6 (R7)

Table 2 Recommended housing wall thickness (recommended)

Housing material	Housing wall thickness
Iron-based	0.75 $(D-F_w)$ and over
Light metal alloy	1.5 $(D-F_w)$ and over

For values of D and F_w, refer to the relevant dimension table.

Shaft and housing requirements

Table 3 shows the shaft and housing requirements.

Table 3 Shaft and housing requirements (recommended)

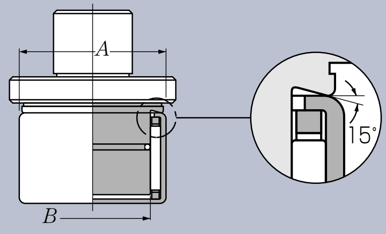
Characteristics	Shaft		Housing	
	Type HF	Type HFL	Type HF	Type HFL
Roundness (max)	IT3 (IT4)		IT4 (IT5)	
Cylindricality (max)	IT3 (IT4)		IT4 (IT5)	
Surface roughness	0.2a		1.6a	
Surface hardness	HRC58—64		—	
Effective hardened layer depth (min)	0.4mm		—	

Lubrication

Oil lubrication is optimum for these one-way clutches, but generally grease lubrication is mostly applied to this type of one-way clutch. **NTN** one-way clutches are filled up with a suitable grease. These clutches need no further grease replenishment, but subject to general applications.

In replenishing, good care must be exercised of too much grease filling. Too much filling could cause interference with smooth clutching.

For selection of an appropriate lubricant, contact **NTN** Engineering for technical assistance.



$A = D - (0.2\sim0.3)$ mm
$B = F_w - (0\sim0.025)$ mm
D = Outer diameter of one-way clutch mm
F_w = Roller inscribed circle diameter mm
(Refer to applicable Dimensions Table.)

Fig. 3

Allowable operating temperature

For **Type HF** and **HFL**···Oil lubrication : -10 to 120˚C
Grease lubrication : -10 to 70˚C

When intending to use the oneway clutch at the upper or lower limit for its allowable operating temperature range, contact **NTN** Engineering for technical assistance.

How to mount

It is convenient to use a press-fitting mandrel as illustrated in **Fig. 3** for assembling and mounting these one-way clutches. In that case, press-fit the outer ring, with its stamped mark side kept in contact with the mandrel shoulder.

In assembling, be careful to prevent the outer ring from twisting. Avoid to hammer directly the outer ring and, in press-fitting, bring a proper jig in contact with the outer ring side face without fail. Furthermore, when press-fitting in an housing with shoulder, good care must be exercised to prevent the bearing side face from coming into contact with the housing shoulder and to thereby avoid deformation of the bearing.

Also, shaft can be easily assembled by turning it in clutch idling direction. Where impossible to do so, provide the shaft end with a tapered (chamfered) guide to facilitate assembling-in.

Precautions in selecting

NTN is verifying the functions of its oneway clutch products under various test conditions. However, if an **NTN** oneway clutch is used under a higher load torque, in high oscillation cycles and fine oscillation mode, or when a greater radial load acts on the oneway clutch, or if the hardness of the mating shaft is low, the life of oneway clutch can become shorter.

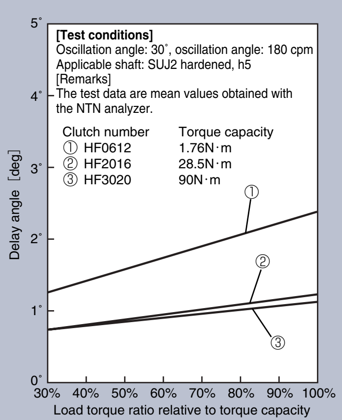
Furthermore, lock failure could occur in the cases of fast idling speed, frequent use in idling, and application incurring vibration.

When using these one-way clutches under the special conditions stated above, feel free to contact **NTN** for further instructions.

If loss of the clutching function of oneway clutch (slipping occurs during engagement motion) can impose severe damage to personnel or equipment, a positive safety device needs to be separately provided for the machine.

■Delay angle

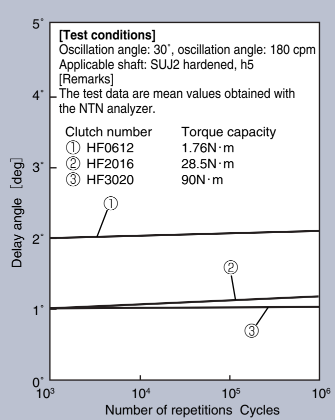
"Delay angle" means the difference ($\theta_i - \theta_o$) between the angle of rotation of the input shaft (θ_i) and the angle of rotation of the output shaft (θ_o). The delay angle of **NTN** oneway clutch can vary depending on the oneway clutch designation and the magnitude of torque the oneway clutch carries. The chart in the right graphically illustrates the trend in relation between load torque and delay angle (data measured with an **NTN** analyzer).



Type HF
Relation between load torque and delay angle

■Life

NTN has verified that even if a torque as high as the torque capacity of **NTN** oneway clutch products is exerted, and when the number of engagement cycles exceeds 10^6, change in the delay angle on **NTN** oneway clutches is small (data obtained from the **NTN** analyzer).



Type HF
Change in delay angle owing to increase in number of repeated cycles

Bottom Roller Bearings for Textile Machinery

These are needle roller bearings that support the bottom rollers (fluted rollers) on fine spinning machines, roving frames or drawing frames. **Type FRIS** is applied to a fine spinning machine and a roving frame, and **Type FR** is applied to a drawing frame.

Types and construction

Bottom roller bearing **FRIS** is used to support the bottom rollers of a fine spinning machine and a roving frame. The outer ring outer profile of this bearing type is spherical, which can allow, to some extent, mounting error in the bottom rollers. On the other hand, the inne ring is provided with a rib at its both ends and a clea between the outer ring and each inner ring rib is minimized. Furthermore, the rib outer surface is knurled to prevent invasion of cotton pieces into the bearing.

These bottom roller bearings are classified into internationally interchangeable **A-series** bearings with bearing fixing saddle (to fix a bearing to a support sta and **B-series** bearings adaptable to the dimensions of JIS Fluted Rollers.

A-series bearings are further classified into one bearing type (suffix **SA**) wherein inner ring and outer ri are separable from one another according to saddle type and another bearing type (suffix **SB**) wherein inner ring and outer ring are non-separable. Of course, these bearings can also be supplied without saddle.

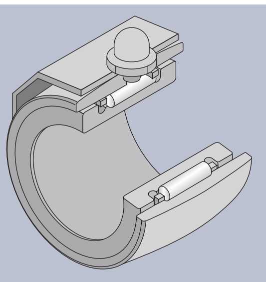

Fig. 1 Type FRIS··SA

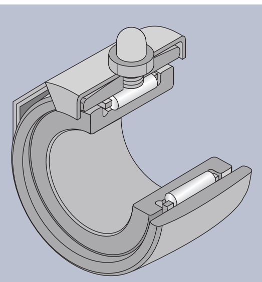

Fig. 2 Type FRIS··SB

On the other hand, **B-series** bearings are further classified into bearing type with grease nipple (suffix **N**), bearing type with knock pin on its outer ring (suffix **P**) and bearing type with knock hole on its outer ring (suffix **W**) (latter two types-classified by the fixing method applied).

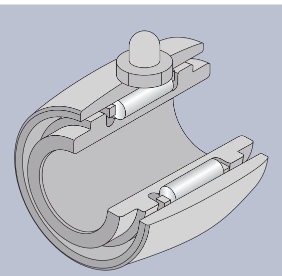

Fig.3 Type FRIS

These bearings can be supplied with saddle thereon o request, similarly to **A-series**.

Type **FR** is used to support the rollers of a drawing frame. This bearing type is composed of two drawn cup type needle roller bearings which are configured in a housing. These have no inner ring and use a shaft as direct raceway surface. Synthetic rubber seal is fitted in the both ends of the housing. This bearing type is fixe a support stand with knock pins press-fitted in the housing. The knock pin is provided with an grease ho to enable grease replenishing.

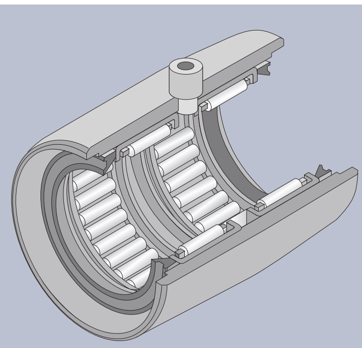

Fig. 4 Type FR

Composition of bearing number

The bearing number comprises type code, dimension code [diameter (d or F_w)] and a suffix.

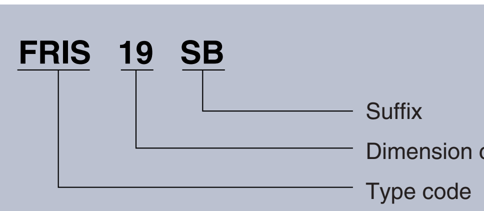

Fig.5

Bearing fits

Table 1 shows bearing fits on/in shaft and housing.

Table 1 Bearing fits

Bearing type	Shaft		Housing (stand)
	Screwed joint	Spline joint	
FRIS	g5 (g6)	j5 (j6)	H10
FR	h5 (h6)		H10

Precautions for mounting

(1) For the shaft shoulder dimensions of the Type FRIS, refer to the dimensions d and G in the relevant dimension table. To be able to prevent entanglement with fly and avoid adverse effect onto spinning quality, it is necessary to promptly remove entangling fly without stopping the machine. In this context, the conditions that must be satisfied to allow the bearing to fully develop its functions and maintain spinning quality by provide sufficiently deep and wide shaft shoulder.

(2) To axially position the bottom roller connected to the machine, use a thrust bearing on the gear end side so that axial movement of the bottom roller is positively prevented.

(3) When rinsing the bottom roller with cleaning liquid such as light oil, be careful not to allow the cleaning liquid to enter the bearing.

(4) When installing the bearing to a stand, position the outer ring to the middle of the inner ring width.

(5) Carefully install the bottom roller so that its runout is not greater than 0.05 mm.

Tensioner Pulleys for Textile Machinery

These pulleys are used to guide and tension the tapes and belts driving the spindles of a fine spinning machine, a roving frame, a false twister, etc.

A pulley drawn precisely from steel plate by precision deep drawing is press-fitted in the outer ring of shaft bearing in in place of inner ring.

Types and construction

Single-row or double-row ball bearing is built in this pulley, which is internally prefilled with lithium soap base grease. Grease is replenished through a grease hole which is internally provided in the stud. Two different mounting methods are available as follows for these pulleys; one method is to bolt a pulley to the roller ca of machine with holder bolt using a special-purposed holder (Type code **JF··S**) and another method is to bolt directly a pulley to machine frame using the bolting hol drilled in the stud and a corresponding hexagon head bolt. A knock pin press-fitted in the stud end face is to lock the bolt after tightened.

When a pulley is directly bolted to machine frame, provide the hexagon head bolt center with a grease through-hole for grease replenishing and screw a grease nipple in its end face.

In mounting a double-row ball bearing type tension pulley, insert the stud directly into machine frame and tighten it with nut, without using the special-purposed holder. Replenish grease using the box nut.

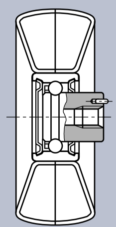

Fig. 1
Single-row bearing type ension pulley

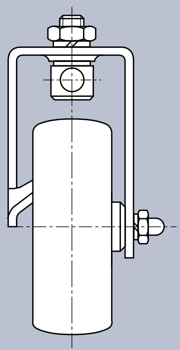

Fig. 2
Tension pulley with holder

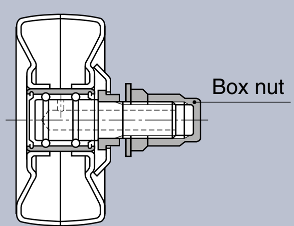

Fig. 3
Double-row bearing type tension pulley

Composition of pulley number

The pulley number of a given **NTN** tension pulley consists of a type code (**JPU**), dimension code [pulley outside diameter (D)] and a suffix. A pulley having a special holder is marked with the holder number of that holder added to the suffix.

(How to read this table)
For example, for conversion from 38˚C to ˚F read 38 in 4th row box (10th line from the top) and then read the right-side ˚F box.
38˚C is equivalent to 100.4˚F upon reading. Furthermore, for conversion from 38˚F to ˚C read the left-side ˚C box.
˚F38 is equivalent to 3.3˚C upon reading.

$C = 5/9(F-32)$
$F = 9/5C+32$

Approximate conversion values against Vickers hardness of steel materials[1)]

[How to read the table]
For example, for conversion from 10kgf to N read 10 on center stage of 1st row box and then read the right-side N. 10kgf is equivalent to 98.066 upon reading. Furthermore, for conversion from 10N to kfg read the right side kgf box. 10N is equivalent to 1.0197kg upon reading.

1kgf＝9.80665N
1N＝0.101972kgf

Ordinary tolerance for cutting dimensions

JIS B 0405

Ordinary tolerance is applied to cutting dimensions for which special accuracy is not required functionally and, therefore, applicable tolerances are indicated in batch, without individual indication of them, in relevant specification, drawings, etc.

Ordinary tolerances shall be indicated by either one of the following methods (1) and (2).

(1) Numerical value table for each dimensional division
(2) Applicable Standard No. and tolerance class
Ex. Ordinary tolerance shall conform to the "Medium Class" specified in JIS B 0405.

Unit : mm

Dimensional division \ Class	Fine class	Medium class	Coarse class
0.5 and over 3 incl.	±0.05	±0.1	–
Over 3 6 incl.	±0.05	±0.1	±0.2
Over 6 30 incl.	±0.1	±0.2	±0.5
Over 30 120 incl.	±0.15	±0.3	±0.8
Over 120 315 incl.	±0.2	±0.5	±1.2
Over 315 1000 incl.	±0.3	±0.8	±2
Over 1000 2000 incl.	±0.5	±1.2	±3

Reference: The numerical values given above every each of "Fine Class", "Medium class" and "Coarse Class" match "Fine series, Medium series", and Coarse series" specified in ISO 2768 (Permissible Machining Variations in Dimensions without Tolerance Indication).

Ordinary tolerances for castings

JIS B 0403

This Standard specifies the ordinary tolerances for the as-casted length and wall thickness dimensions (hereinafter referred to as" ordinary tolerance") of gray castings and spherical graphite castings molded using sand molds (excluding precision mold and other equivalent).

The ordinary tolerance shall be indicated by either one of the following methods (1) and (2).

(1) Numerical value table for each dimensional division
(2) Applicable Standard No. and tolerance class
Ex. JIS B 0403, Coarse class

Ordinary tolerance for length

Unit : mm

Dimensional division \ Material / Class	Gray castings Fine class	Gray castings Coarse class	Spherical graphite castings Fine class	Spherical graphite castings Coarse class
120 incl.	±1	± 1.5	±1.5	± 2
Over 120 250 incl.	±1.5	± 2	±2	± 2.5
Over 250 400 incl.	±2	± 3	±2.5	± 3.5
Over 400 800 incl.	±3	± 4	±4	± 5
Over 800 1600 incl.	±4	± 6	±5	± 7
Over 1600 3150 incl.	–	±10	–	±10

Ordinary tolerance for wall thickness

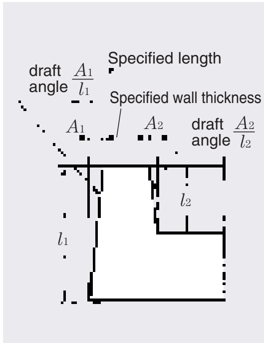
Unit : mm

Dimensional division \ Material / Class	Gray castings Fine class	Gray castings Coarse class	Spherical graphite castings Fine class	Spherical graphite castings Coarse class
10 incl.	±1	±1.5	±1.2	±2
Over 10 18 incl.	±1.5	±2	±1.5	±2.5
Over 18 30 incl.	±2	±3	±2	±3
Over 30 50 incl.	±2	±3.5	±2.5	±4

Dimension-A for draft angle

Unit : mm

Dimensional division l	Dimension A (max)
18 incl.	1
Over 18 30 incl.	1.5
Over 30 50 incl.	2
Over 50 120 incl.	2.5
Over 120 315 incl.	3.5
Over 315 630 incl.	6
Over 630 1000 incl.	9



Remarks : l means l_1 and l_2 in the above sketch.
A means A_1, A_2 in the above sketch.

Ordinary tolerances for press-formed metal parts

JIS B 0408

This Standard specifies the ordinary tolerances for the punching, bending and drawing dimensions, bending angle of press-formed metal parts (hereinafter referred to as "ordinary tolerance").

Ordinary tolerance is applied to the dimensions for which special accuracy is not required functionally and, therefore, applicable tolerances are indicated in batch, without individual indication of them, in relevant specification, drawings, etc.

Ordinary tolerance shall be indicated by either one of the following methods (1) and (2).

(1) Numerical value table for each dimensional division
(2) Applicable Standard No. and tolerance class
Ex. JIS B0408, Class-A

Ordinary tolerance for punching

Unit : mm

Dimensional division	Class		
	Class-A	Class-B	Class-C
6 incl.	±0.05	±0.1	±0.3
Over 6 30 incl.	±0.1	±0.2	±0.5
Over 30 120 incl.	±0.15	±0.3	±0.8
Over 120 400 incl.	±0.2	±0.5	±1.2
Over 400 1000 incl.	±0.3	±0.8	±2
Over 1000 2000 incl.	±0.5	±1.2	±3

Ordinary tolerance for bending angle

Unit : mm

Dimensional division	Class		
	Class-A	Class-B	Class-C
6 incl.	±0.1	±0.3	±0.5
Over 6 30 incl.	±0.2	±0.5	±1
Over 30 120 incl.	±0.3	±0.8	±1.5
Over 120 400 incl.	±0.5	±1.2	±2.5
Over 400 1000 incl.	±0.8	±2	±4
Over 1000 2000 incl.	±1.2	±3	±6

Ordinary tolerances for sheared metal plates

JIS B 0410

This Standard specifies the ordinary tolerances for the shearing width and ordinary tolerances for the straightness and perpendicularity (hereinafter generically referred to as "ordinary tolerance") of metal plates of 12mm and less in thickness which were sheared by direct shearing machines such as gear pusher, square shear, etc.

The ordinary tolerance shall be indicated by either one of the following methods (1) and (2).

(1) Numerical value table for each dimensional division
(2) Applicable standard No. and tolerance class

Ex. 1. JIS B 0410, Class-B
2. Cutting width, straightness: JIS B 0410, Class-B
Perpendicularity: JIS B 0410, Class-A

Definition of the terms: The terms used in this Standa are as defined in JIS B 0111 (Terminology relating to press machines) and, in addition, defined as follows.

(1) Cutting width: Distance from one side sheared by shear cutter to opposite side, as illustrated in Fig. l
(2) Cutting length: length of one side sheared by shea cutter, as illustrated in Fig. l.

Ordinary tolerance for shearing width — Unit : mm

Ordinary tolerance for sintered metal parts

JIS B 0411

This Standard specifies the ordinary tolerance which is applied to the machining dimensions of sintered mechanical parts and sintered oil-contained bearing, of sintered metal parts, but excluding machining methods other (e.g. cutting, etc.) than the machining method specific for sintered metal parts.

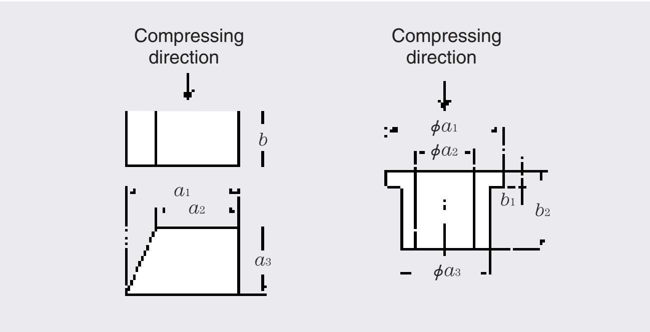
Ordinary tolerance is applied to the dimensions for which special accuracy is not required functionally and, therefore, applicable tolerances are indicated in batch, without individual indication of them, in relevant specification, drawings, etc.

Ordinary tolerance shall be indicated by either one of the following methods (1) and (2).

(1) Numerical value table for each dimensional division
(2) Applicable Standard No. and tolerance class
Ex. JIS B0411, Fine Class

Definition of terms: The terms used in this Standard are as defined below.

(1) Width: Perpendicular dimension against compressing direction in compressive molding of powders, as illustrated in Fig. a.
(2) Height: Dimension parallel to compressing direction in molding of powders, as illustrated in Fig. b.



Class: The ordinary tolerance class shall be three classes of “Fine Class”, “Medium Class” and “Coarse class”.
Reference: The numerical values every each class of “Fine Class”, “Medium Class” and “Coarse class” match “Fine Series, Medium Series and Coarse Series specified in ISO 2768 (Permissible machining variations in dimensions without tolerance indication)

Ordinary tolerance for width

Unit : mm

Dimensional division \ class	Fine class	Medium class	Coarse class
6 and less	±0.05	±0.1	±0.2
Over 6 - 30 incl.	±0.1	±0.2	±0.5
Over 30 - 120 incl.	±0.15	±0.3	±0.8
Over 120 - 315 incl.	±0.2	±0.5	±1.2

Ordinary tolerance for height

Unit : mm

Dimensional division \ class	Fine class	Medium class	Coarse class
6 and less	±0.1	±0.2	±0.6
Over 6 - 30 incl.	±0.2	±0.5	±1
Over 30 - 120 incl.	±0.3	±0.8	±1.8

Insulated Bearings MEGAOHM™ Series

CAT. No. 3030/E

Insulated Bearings MEGAOHM™ Series : Offering Enhanced Safety and Reliability

Bearings used in electrical equipment such as motors and power generators tend to exhibit electrical pitting as a result of current leakage. **NTN**'s **MEGAOHM**™ **Series** of insulated bearings has been specifically designed to counteract electrical pitting. These bearings are available in both ceramic and resin types suited to a variety of applications. The **MEGAOHM**™ **Series** of insulated bearings offers the following unique advantages:

MΩ series

- **Exhibits insulation resistance of at least 100 MΩ at 500 VDC.**
- **Available in a wide range of variants with various insulating layer materials, high voltage resistance and shock immunity that accommodate diverse user requirements.**
- **Compatible with ISO 492, DIN 620 and JIS 1514 standards.**
- **Available in bore diameters ranging from 50 to 160 mm.**

1 The Mechanism of Electrical Pitting

An electrical current present near a bearing can flow to the inside of the bearing, causing sparks that damage the rolling contact surface. This phenomenon is known as "electrical pitting." When such sparks first occur, circular spots can appear on the rolling contact surface (**Photo 1**). The thermal effects of the sparks can cause the metallurgical composition and hardness in this problematic area to differ from those of the surrounding normal areas, resulting in a white layer, hardened layer and tempered layer. As a result, the problematic area can eventually develop flaking. Furthermore, if the electrical pitting phenomenon progresses, a corrugation pattern (**Photo 2**) can develop that increases running noise and vibration. Consequently, the bearing can no longer adequately function.

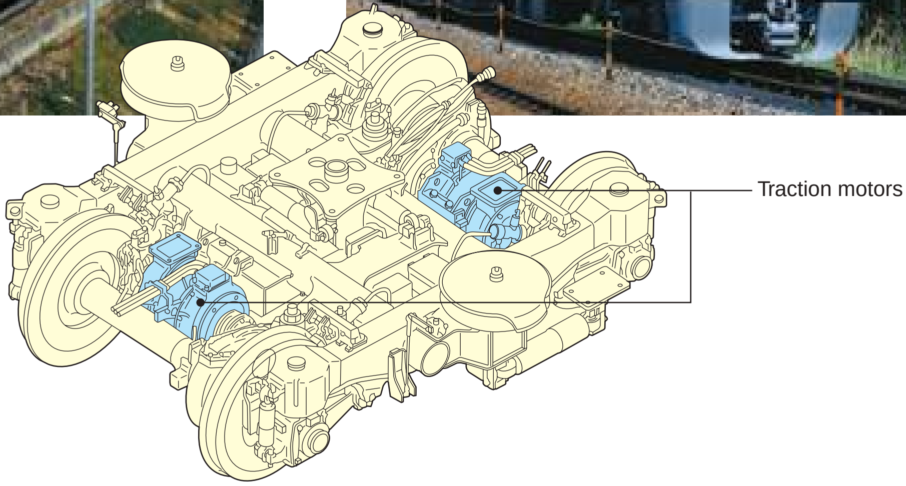
6 Typical Applications

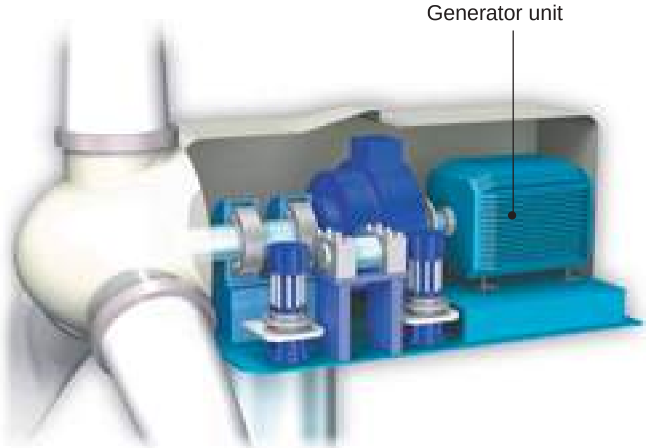
Electric Motors

The insulated bearings MEGAOHM™ Series is widely used in the traction motors of railway cars.
The unique knowledge and experience **NTN** has gained from motor applications in railways- where safety is the No. 1 priority- have contributed to the greatly improved reliability of general-purpose motors.



Power Generators

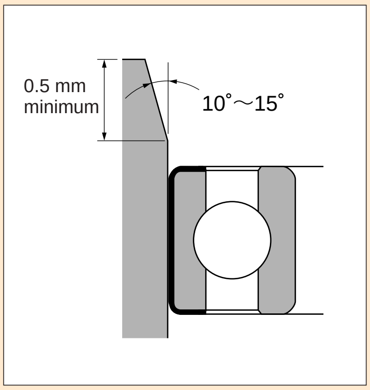
The insulated bearings MEGAOHM™ Series is also used in wind power generation systems, which are one solution to energy issues such as the prevention of global warming. These bearings contribute to the improved reliability of eco-friendly wind power generation systems.



Operating Precautions

To avoid an accident or failure resulting from damage to insulated bearings, carefully observe the following.

- Never drop an insulated bearing or strike it directly with a hammer during installation (**Illustrations 1 and 2**).
- Do not use an insulated bearing if a defect is visible on the surface (**Illustration 3**) or it has an unusual appearance.
- Attaching an electrical conductor to an insulated bearing can lower the bearing's insulation resistance.
- To prevent current flow from the side faces of a bearing, strictly observe the mounting dimensions given in the dimension tables for required shoulder height.
- Providing approximately 15° of relief (illustrated at right) at the entrance to the housing will facilitate assembly.
- For DC motors such as those used in railway cars, earth-ground the shaft during a voltage resistance test.



Relief at entrance of housing bore

Excessive shock can damage the insulating layer, possibly resulting in electrical pitting. Electrical pitting can in turn damage the bearing, leading to abnormal bearing performance and possible faulty operation or failure.

ULTAGE

ULTAGE®

CAT. No. 3019/E

ULTAGE®

IC Tag Integrated Bearing

Improved Maintainability

Direct writing of electronic data

First in the Industry

Features

First in the industry

Record electronic data within the bearing itself.

112 English one byte characters can be read and written into Φ4.5mm IC Tag.

Compact

The data can be read and written with dedicated Reader/Writer.

Compact and light weight Reader/Writer (PDA) will not choose the place for recording the data.
(When applied out of Japan, the warranty of legality to Local Radio Law has to be confirmed.)
Personal Computers can be used with specialized software.

Format

Exclusive format is prepared.

Exclusive format for information is prepared, but it can be adjustable to customers' request.

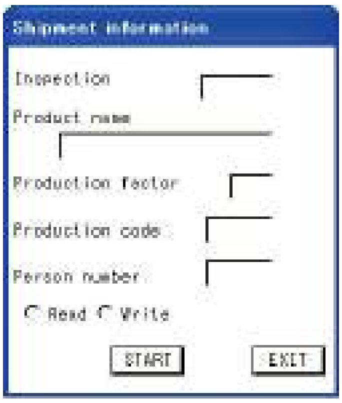
Applications

1. It can be possible to compare the information at maintenance to the original information.
2. It is possible to confirm previous maintenance date, operating hours and others by writing the latest information at the maintenance.
3. The historical data can be saved into PC and it enables to control bearing information of whole machines.(Pen type Reader/Writer is required for PC.)

Dedicated format

Standard format

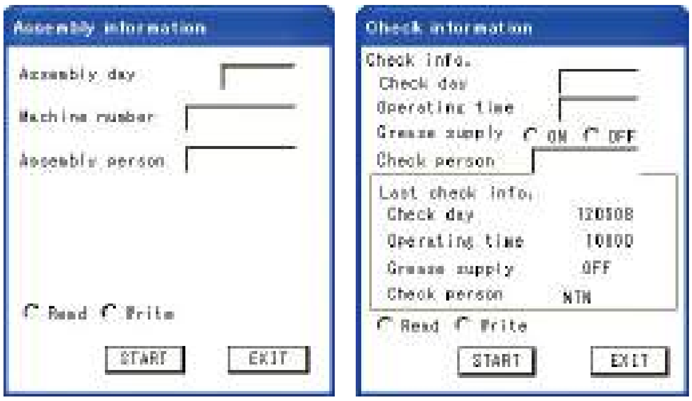
Ex.：Input screen of bearing information



1. Bearing information

Recorded by NTN at shipment time

Ex.：Input screen of bearing management information



2. Bearing management information

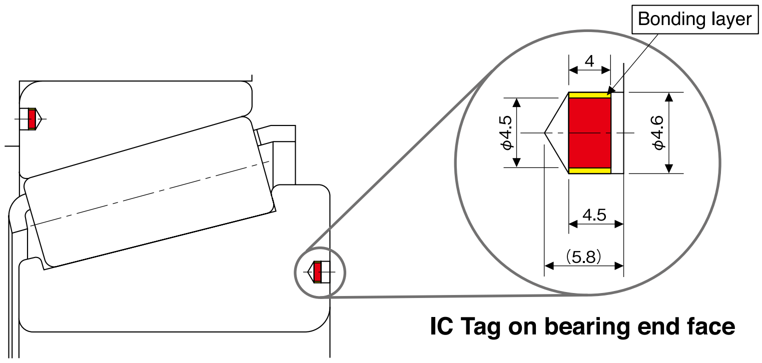
Recorded by the user for maintenance record

"ULTAGE"(a name created from the combination of "ultimate", signifying refinement, and "stage", signifying NTN's intention that this series of products be employed in diverse applications) is the general name for NTN's New generation of bearings that are noted for their industry-leading performance.

ULTAGE Series "IC Tag Integrated Bearing" allows electronic data such as maintenance record, information for replacement, quality records of the bearing saved directly within the bearing itself which can be used for every application.

Applicable bearing

1. Applicable to bearings which have enough space to attach IC Tag. (Φ4.5×4)
   A small hole will be formed on the end face of the bearing.
   In case of small size bearings and thin section bearings, IC Tag could not be attached.
2. IC Tag is good for oil and heat, but if the bearings would be used under special environment,please contact NTN Engineering.



IC Tag on bearing end face

Specifications of IC Tag

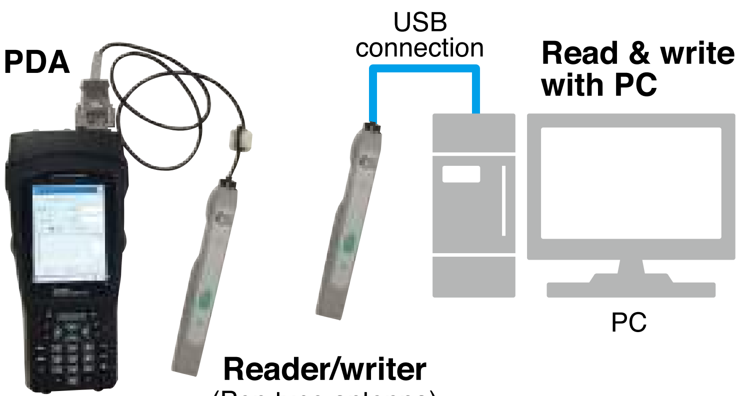
IC Tag
(mounted on end face)

■ **Specification of IC Tag**

Item	Specification
Memory Capacity Including Quality information	112byte
Data retention period	10 years
Data rewritable time	over 100,000 times
Carrier frequency	13.56MHz
Compliance standards	ISO 15693
Communication distance	～2mm
Ambient operating temperature	～120°C
Dimension	Φ4.5mm×4mm

Data retention period, data rewritable time and communication distance are reference values.

Specifications of reader/writer



Reader/writer
(Pen type antenna)

■ **Specification of reader/writer (PDA)**

Item	Specificaion
Carrier frequency	13.56 MHz
Compliance standards	ISO 15693
Ambient operating temperature	-10°C～50°C
Dimension	79mm×164mm×25mm (3.5 inch)
Weight	320g
Charging power	AC100V～250V(50～60Hz)

In case of inability of communication, apply dedicated Antenna Adapter on tip of pen type antenna.

Status of compliance of reader/writer to Local Radio Law

Certified in Japan, Europe, USA, Canada, Mexico, Thailand, Vietnam, Singapore, Malaysia, Indonesia, Philippines, China, Hong Kong,Taiwan, and Korea. Under adjustment in Australia.

IC Tag: Small electronic memory with RFID(Radio Frequency Identification) technologies.

Large Size Tapered Roller Bearings

ULTAGE Metric Series

ULTAGE®

CAT. No. 3035/E

ULTAGE®

Large Size Tapered Roller Bearings

ULTAGE Metric Series

Large size tapered roller bearings (ULTAGE metric series, OD≧ϕ270mm) deliver longer life, higher load ratings, and higher speed capabilities. Developed as the new standard of NTN bearings, the ULTAGE series will contribute to improvements in industrial machinery today and into the future.

Higher Reliability

- Greater high load capacity by optimizing internal design
- Longer maintenance intervals

Higher Load Capability

- Allowable misalignment 0.0017 (6')

※Under conditions of $Fr \leqq 0.35Cr$

Higher Limiting Speed

- Up to 10% increase of allowable speed by optimizing the inner ring, large-end rib, and the roller end

"ULTAGE®" (a name created from the combination of **"Ultimate,"** signifying refinement,and **"Stage,"** signifying **NTN**'s intention that this series of products be employed in diverse applications) is the general name for **NTN**'s new generation of bearings that are noted for their industry-leading performance.

INDEX

1. Features

1.1 The highest level of reliability

The optimized roller crowning delivers a dramatically increased load rating by better distributing load across the roller length, greatly reducing edge stress concentrations as shown in **Fig.1**.

① **Tested life:**
3.0 times larger than conventional bearings

② **Basic dynamic load rating:**
30% larger than conventional bearings

1.2 Allowable misalignment

Misalignment : 0.0017rad (6')

- Optimizations made to the crowning shape allow combinations of 0.35 C_r and misalignment up to 0.0017rad (6') to be used.
- Minimum required load : 0.04C_{0r}

Fig.1 shows the stress distribution when the radial load is below 0.35 C_r. Edge stress is significantly decreased and contact stresses are better distributed along the length of the roller, as compared the stresses resulting from a conventional design.

【Studied conditions】

Bearing size：30316U（φ80×φ170×42.5）

Load：102kN

Misalignment：0.0017rad.

※Since allowable misalignment varies depend on combination of load and misalignment, please consult **NTN** engineering.

1.3 Allowable speed

The optimized design between the roller and inner ring rib end makes it possible to minimize rotational torque and temperature rise, allowing for up to 10% higher allowable speed when compared to a conventional design as shown in **Fig. 2, 3** and **4**.

1.4 Improved demensional stability over time

The special heat treatment to the bearing steel allows for better dimensional stability over time, and reduces dimensional change during operation.

●**Less dimensional change**

1/10 compared with through hardened steel

1/4 compared with carburized steel

1.5 Easily adaptable

Boundary dimensions and tolerance of bearings comply with **ISO 355** (**JIS B 1512**), **ISO 492** (**JIS B 1514**).

2. Bearing Number

2.1 Single row tapered roller bearings

Bearing number : 3 03 28 U UTG

- UTG — Type code : ULTAGE
- U — Internationally interchangeable tapered roller bearings
- 28 — Nominal bore diameter 140mm
- 03 — Dimension series 03
- 3 — Bearing type (Single row tapered roller bearings)

2.2 Double row tapered roller bearings (Outside direction)

Bearing number : 43 03 28X UTG

- UTG — Type code : ULTAGE
- 28X — Nominal bore diameter 140mm
- 03 — Dimension series 03
- 43 — Bearing type (Double row tapered roller bearings (Outside direction))

2.3 Double row tapered roller bearings (Inside direction)

Bearing number : 32 31 32 UTG

- UTG — Type code : ULTAGE
- 32 — Nominal bore diameter 160mm
- 31 — Dimension series 31
- 32 — Bearing type (Double row tapered roller bearings (Inside direction))

3. Dimension Table

Construction and Characteristics

NTN cam followers are stud-type track roller assemblies each comprising a thick-walled outer ring encompassing integral rollers. The cam follower is designed to operate with its outer ring rolling on the track.

Because it is run in direct contact with the track, the outer ring is designed with a thick wall capable of withstanding an impact load.

The outside surface of the outer ring is either spherical or cylindrical in shape. A spherical outer ring can effectively withstand edge loads that result from mounting error.

Because the cylindrical outer ring is in contact with a larger contact area of the associated track surface, the contact surface pressure is lower. Thus, this type of outer ring can bear a larger load compared with spherical outer rings and can be used even if the hardness of the associated track surface is low.

NTN cam followers can be categorized into a caged type and full-complement roller type. With the caged type, the rollers are guided by the cage, making this type suitable for high-speed applications.

The full-complement roller type, by contrast, has an increased load rating, making it suitable for high-load applications (low-speed operation). The double-row cylindrical roller type (NUKR type), however, can bear an even higher load.

In addition to unsealed configurations, **NTN** cam followers are available in configurations incorporating either a rubber seal or a labyrinth seal (shield plate). Cam followers with a seal and full-complement roller-type cam followers are prelubricated with standard grease (lithium soap grease).

Both types have an oil hole at the end of the stud that allows for relubrication with grease. This arrangement enables the user to replenish the grease using the grease nipple provided as standard accessories.

The stud rib of an **NTN** cam follower is provided with a hexagonal socket, a tapped hole or a slot for a flat-blade screwdriver.

To secure a cam follower to its associated housing, tighten the hexagonal nut threaded onto the stud while preventing rotation of the stud with a screwdriver or Allen key.

NTN also offers a unique type of cam follower whose stud features an eccentric axis on its threaded portion. This arrangement can be used to compensate for any variation - within the range of the eccentricity - in the stud mounting hole position.

構造と特徴

NTNカムフォロアは，肉厚の外輪にころを組み込んだスタッド付きのトラックローラで，軌道（トラック）上を外輪が転がり運動する。

外輪は直接トラックに接触させて使用するため，肉厚の外輪として衝撃荷重にも耐えられるよう設計している。

外輪外径は球面と円筒面があり，球面外輪は，取付誤差によるエッジロード緩和に有効である。

また，円筒外輪は相手トラック面との接触面積が大きいので，接触面圧が軽減され球面外輪に比べ大きな荷重や相手トラック面の硬度が低い場合でも使用できる。

NTNカムフォロアは保持器付き形と総ころ形とがあり，保持器付き形は保持器によってころが案内されるため，高速回転での使用に適している。

また，総ころ形は保持器付き形に比べ定格荷重が大きく高荷重（低速運転）での用途に適しており，複列円筒ころ形（NUKR形）はさらに高荷重を負荷することができる。

NTNカムフォロアはシールなしの他に，シール有り，ラビリンスシール（シールド板）付きの形式が用意されており，シール付き及び総ころ形は標準グリース（リチウム石けん基グリース）が封入されている。

なお，いずれの形式でもスタッド端部にグリースを補給するための給脂孔が設けられており，付属のグリースニップルを用いて給脂することができる。

NTNカムフォロアはスタッドつば部にドライバ溝が付いた形式と，六角穴やタップ穴が付いた形式が用意されている。

カムフォロアを相手ハウジングへ取付ける際は，ドライバまたは六角レンチを用いてスタッドの回り止めをし，スタッドねじ部に取付けた六角ナットを締め込むことにより固定できる。

また，スタッドねじ側の軸心を偏心させた形式も用意しており，スタッド取付穴位置のばらつきを偏心量の範囲内で調整することができる。

Lubrication and Method for Grease Replenishment

Lubrication

Cam followers with synthetic rubber seals (LL suffix) and full-complement roller types are pre-filled with lithium soap base grease. They can be used in the operating temperature range of -20 to +100˚C.

Please contact **NTN** if a grease with better low-temperature characteristics is desired.

Unsealed cage-type cam followers are not prelubricated. If a prelubricated type is needed, feel free to contact **NTN**.

Additionally, **NTN** Bearings with Solid Grease, which have solid lubricant with less leakage than conventional grease, are also available on request. Feel free to contact **NTN** for detailed information.

The outer ring outer surface of bearing and the track surface must both be lubricated. Failure to lubricate could result in premature bearing failure.

Method for Grease Replenishment

Replenishment of grease can be performed by attaching a grease-gun to a grease nipple on the flange end face or threaded-side end face of the stud. Be sure to first plug the grease-feed hole or the tapped hole on the opposite side with a special-purpose plug or a threaded plug with hexagonal socket.

A grease nipple and plug are enclosed in each cam follower package. Attach them to the cam follower before mounting unit.

Both special grease nipples and those specified in the JIS Standard are available. The dimensions thereof and the applicable bearing types are specified in **Tables 3** and **4** respectively.

Furthermore, special press-fit type plugs and threaded plugs with hexagonal sockets are available. The dimensions thereof and the applicable bearing types are specified in **Tables 5-1**, **5-2** and **Table 6**.

When using special-purpose press-fit plugs, press-fit into the grease feed hole using a mandrel as shown in **Table 7**.

潤滑と内部への供給・補給方法

潤滑

合成ゴムシールを装着した形式（接尾記号LL）及び総ころ形式には，リチウム石けん基のグリースが前もって封入され，−20～+100℃の温度範囲で使用できる。

なお，常時0℃以下の場合には，低温特性に優れたグリース封入品仕様を推奨しますので**NTN**へ御照会ください。

保持器付き形でシールなし品には，グリースは封入されていません。封入品が必要な場合は**NTN**へ御照会ください。

なお，潤滑剤の漏れが少ない固形グリースを封入した**NTN**ポリルーブベアリングもありますので，**NTN**へ御照会ください。

また，大気中での低発塵性が必要な場合には低発塵用グリースを封入することもできますので**NTN**へ御照会ください。

軸受の外輪外径面と軌道（トラック）間にも潤滑が必要です。潤滑されていないと，軸受の損傷が早期に発生する場合があります。

供給・補給方法

グリースガン等を用いてスタッドのフランジ端面，またはねじ側端面に取付けられたグリースニップルにより行う。給脂しない側の給脂穴またはタップ穴はプラグ（専用プラグまたは六角穴付きねじプラグ）により塞ぐ。

グリースニップル及びプラグはパッケージに同封されているので，カムフォロアを組付ける前に取付ける。

グリースニップルには専用のものとJISで定められたものがあり，その寸法を**表3**に，適用軸受形式を**表4**に示す。

また，プラグにも専用の圧入タイプと六角穴付きねじプラグがあり，その寸法を**表5-1,2**に，適用軸受形式を**表6**に示す。

専用の圧入タイププラグの場合は，**表7**に示す寸法のマンドレルを用いて給脂穴に圧入する。

8	15	7.8	2.5

Installation

(1) Make the face height at the cam follower mount greater than "e" dimension given in the applicable Dimension Table. (**Fig.2)**
Furthermore, make the chamfer of the stud mounting hole as small as possible (around 0.5×45˚) to bring the side face and housing into precise contact.

取付け関係

（1）カムフォロアの取付け部における側面高さは，寸法表に記載の"*e*"寸法より大きくとる（**図2**）。スタッド取付け穴の面取りは，なるべく小さくし（0.5X45˚ 程度），側板の側面を正確に当てるようにする。

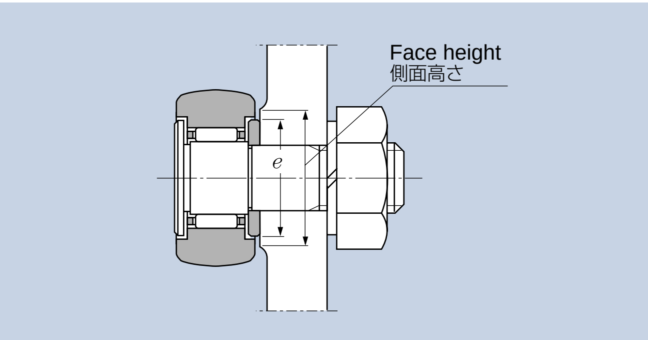

Fig.2

(2) Don't hammer directly the cam follower rib. Doing so may cause damage to the rib and eventual bearing failure.

（2）**カムフォロアのつば部を直接ハンマなどで叩かないこと。つば部が割れたり，回転不良の原因となる。**

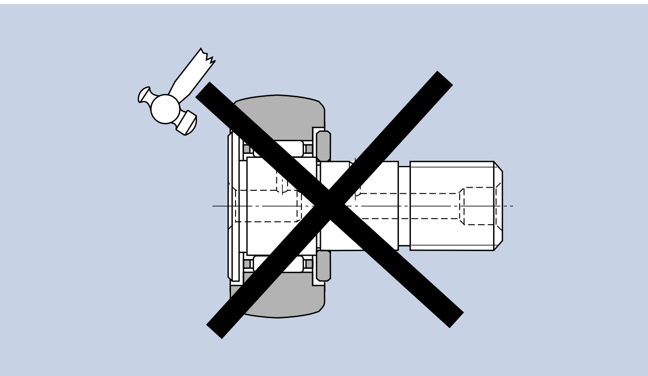

Fig.3

(3) The oil hole position on the stud raceway surface is designated by the **NTN** mark stamped on the stud rib surface. Mount the stud so the oil hole is located opposite the load zone. (**Fig. 4**) If the oil hole is located within the load area, it may result in shorter life of the follower.

（3）スタッドの軌道面にある油穴位置は，スタッドのつば面の**NTN**マークで示しており，非負荷域（荷重を受けない側）に取付ける。（**図4**）
油穴が負荷域にあると，短寿命の原因となる。

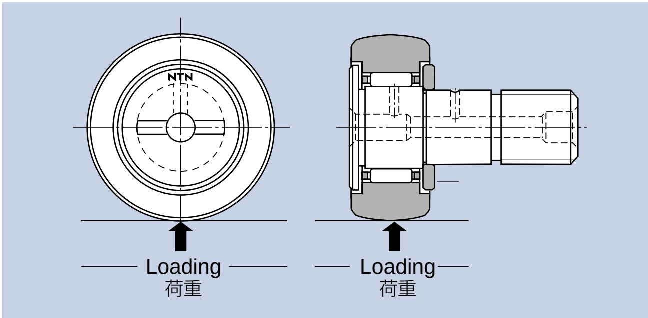

Fig.4

(4) In applications where the stud and nut may loosen due to a wide amplitude of vibration during operation, **NTN** recommends the mounting methods illustrated in **Fig. 5**.

（4）特に振動の激しい使用条件で取付け用のねじの緩む恐れのある場合は，**図5**のような方法がある。

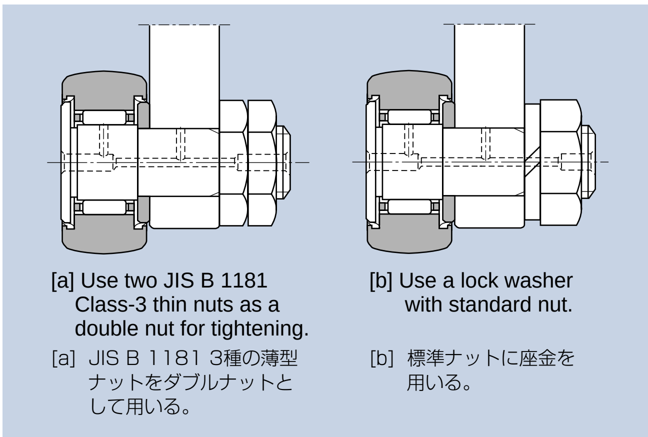

Fig.5

(5) The stud is subjected to bending stress and tensile force arising from bearing load. Tighten the stud screws with tightening torque which does not exceed the torque value specified in applicable Dimension Table. **Overtightening could result in damage to the threaded portion.**

(6) A hole is provided in the center of the stud as illustrated in **Fig. 6**. Use this hole for locking the follower in place or grease replenishment.

(5) スタッドは軸受荷重による曲げ応力及び引張力を受けるので，ねじの締付トルクは寸法表の値を超えないように締付ける。

締付トルクが大きすぎると，ねじ部が破断することがある。

(6) スタッド中央の軸心に直角に設けた穴は，**図6**のような回り止め，またはグリースの補給用として用いる。

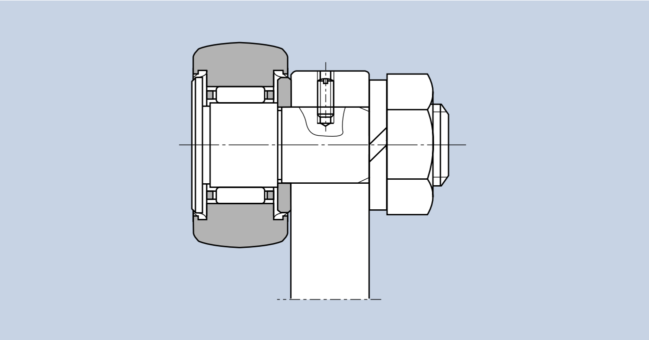

Fig.6

(7) For mounting and adjustment of eccentric stud type cam followers, follow the instructions below.

1. Insert the stud in the mounting hole so that the **NTN** mark (showing oil hole position) is located opposite of the loaded area of the bearings as illustrated in **Fig. 4**.
2. Turn the stud using the recessed slot on the stud head or the threaded plug with hexagonal socket to adjust the clearance with the mating contact surface.
3. After adjustment, tighten the stud nut to the tightening torque described in the applicable Dimensions Table.

(7) スタッド偏心形カムフォロアの取付け調整は，次のように行う。

1　荷重が，作用する方向に対し，スタッドを**NTN**マーク（油穴位置）が**図4**の位置になるように取付け穴を挿入し，ナットを軽く締込む。この時スタッドは，回るようにしておく。

2　スタッド頭部のドライバー溝又は，付属の六角穴付きねじプラグをスタッドに取付けスタッドを回転させて，相手接触面とのすきまを調整する。

3　調整が終わったら，スタッドが，回らないように，ナットを寸法表記載のトルクで締付ける。

NTN cam follower are generally mounted by a stud supported on only one side. This cantilevered load arrangement can lead to an increase in bearing clearance over time due to wear from uneven load distribution within the bearing.

To ensure stability of equipment , check that the clearance between the stud and mounting hole is sufficiently small to prevent uneven loading.

NTNカムフォロアは，一般的に片持ちで取付けるため，継続使用によるはめあいのゆるみの影響で不均一な荷重（片当り）が軸受に作用する場合があります。設備安定稼動のため，はめあいのゆるみには十分な注意が必要です。

Track Load Capacity of Cam Followers and Roller Followers

The track load capacity is calculated by determining the standard hardness (standard tensile stress) from the relation between the hardness and pure tensile force on the material, and by the relation between the standard tensile stress and Hertz stress.

The method of determining the standard hardness (standard tensile stress) varies from manufacturer to manufacturer. **NTN** has chosen to use the hardness-tensile stress relation table at the end of the JIS Handbook for Steel (approximate values in the revised conversion table in JIS Z 8413).

For the standard hardness (tensile stress) of HRC40, we selected the following:

σ = 1245 MPa (127 kgf/mm^2).

Correction factors for track load capacity

The greater the hardness of the track material, the greater the tensile stress of the track material, which results in a greater track load capacity. The true track load capacity is determined under this assumption by multiplying the track load capacity correction factor in **Table 8** by the corresponding track load capacity in the same table.

Note: The track load capacity determined by this method is based on a pure tensile stress and is not an allowable Hertz stress. Generally, a stress (relative stress) that causes creep on a material is greater than a tensile stress. In the case of a static load in particular, the track load capacity determined by the above-mentioned method can be considered to include a margin of safety.

Example: Determine a track load capacity T_c', at a given hardness by using a track load capacity correction factor.

The track load capacity T_c' can be determined by finding a track load capacity T_c in the dimension table and a track load capacity correction factor G in **Table 8**. The procedure is as follows:

$T_c' = G \times T_c$

For the NATR15X type roller follower with hardness HRC50:

T_c＝ 11,900N（1,220kgf），　G＝1.987

∴ T_c'＝1.987×11,900N（1,220kgf）

＝23,645N（2,424kgf）

カムフォロア・ローラフォロアのトラック負荷容量

トラック負荷容量は，硬度と材料の純引張応力における関係で基準硬度（基準引張応力）を設定し，その応力とヘルツ応力の関係から求めた。

基準硬度（引張応力）のとり方は各社で若干異なるが，ここでは，硬度ー引張応力の関係として鉄鋼JISハンドブック巻末表を用いた（JIS Z8413改訂案換算表による近似数値)。

基準硬度（引張応力）として

HRC40ではσ＝1 245MPa（127kgf／mm^2）を採用した。

〈トラック負荷容量補正係数〉

材料は，硬度の増加とともに引張応力が増大するが，それに伴ってトラック負荷容量も増大する。この場合は**表8**に示すトラック負荷容量補正係数をトラック負荷容量に乗じて求めることができる。

注) ここで求めたトラック負荷容量は，純引張応力を基準としており，許容ヘルツ応力ではない。一般に材料にクリープを起こす応力（比応力）は引張応力より大きく，特に静的荷重の場合，今回のトラック負荷容量は安全側の値となる。

例) トラック負荷容量補正係数を用いてある硬さのトラック負荷容量T_c'を求める場合

寸法表記載値のトラック負荷容量をT_c，当該硬さにおけるトラック負荷容量補正係数をGとすると，そのときのトラック負荷容量T_c'は

T_c'＝G・T_c

となる。

NATR15Xで硬度HRC50の場合

T_c＝ 11 900N（1 220kgf），　G＝1.987

∴ T_c'＝1.987×11 900N（1 220kgf）

＝23 645N（2 424kgf）

Track Load Capacity of Cam Followers and Roller Followers
カムフォロア・ローラフォロアのトラック負荷容量

Track Load Capacity Calculation Process

- With a cylindrical outer ring

$$\sigma_{max}=60.9\sqrt{\frac{T_c \Sigma \rho}{B_{eff}}}$$

- With a spherical outer ring

$$\sigma_{max}=\frac{187}{\mu \nu}\sqrt[3]{(\Sigma \rho)^2 T_c}$$

σ_{max}=1,245MPa（127kgf／mm²）

T_c　：Track load capacity（N {kgf} ）
$\Sigma \rho$　：Sum of curvatures
B_{eff}　：Effective contact length（mm）
that is, (outer ring width－chamfer×2)
$\mu \nu$　：Factor governed by curvature

参考（トラック負荷容量 算出プロセス）

- 外輪形状円筒の場合

$$\sigma_{max}=60.9\sqrt{\frac{T_c \Sigma \rho}{B_{eff}}}$$

- 外輪形状球面の場合

$$\sigma_{max}=\frac{187}{\mu \nu}\sqrt[3]{(\Sigma \rho)^2 T_c}$$

σ_{max}=1 245MPa（127kgf／mm²）

T_c　：トラック負荷容量（N {kgf} ）
$\Sigma \rho$　：曲率の和
B_{eff}　：有効接触長さ（mm）
ここでは（外輪幅－2×チャンファ）
$\mu \nu$：曲率で決まる係数

Outer Ring Strength

The outer ring should not break under normal operating loads. When considering outer ring strength when the cam follower is used under an impact load or heavy load, use the following method for calculating the outer ring strength.

The forms of the outer ring are illustrated in **Fig. 7**. The outer ring strength is calculated with the expressions given below. The outer ring breaking strength is the breaking strength when the rollers are supported in a bridge configuration.

Generally, the breaking stress of bearing steel can be assumed to be 1760 MPa (180 kgf/mm^2). However, in our experience we have found it preferable to assume a breaking stress value with a safety margin [1170 MPa (120 kgf/mm^2)] in order to reflect stress concentration. The outer ring should not break under normal operating loads. However, if an impact load or heavy load is expected on the outer ring, it is necessary to check the breaking strength of the outer ring.

It is recommended to use 196MPa {20kgf/mm^2} or less for continuous use.

$$P=\frac{4\pi}{1+f(\alpha)}\times\frac{D-2h}{h(D-2h_2)^2}\times I\times\sigma$$

where

$$f(\alpha)=\frac{(\pi-\alpha)\sin\alpha-(1+\cos\alpha)}{2\cos\alpha}$$

$$\alpha=\frac{\pi}{Z}\ (\text{rad.})$$

P : Breaking load (N)
I : Outer ring cross-section secondary moment (mm^4)
Z : Number of rollers
σ =Breaking stress (MPa)
D, h, h_2 : See **Fig. 7** (mm).

外輪強度

一般的には通常使用荷重であれば外輪が破壊することはないが，衝撃荷重，重荷重使用時の検討を実施する場合の計算方法を以下に示す。

それぞれの外輪形状を**図7**とし，下記の式により求める。この場合の外輪破壊強度は，ころのブリッジ状態の破壊強度をいう。

破壊応力のとり方として，一般には，軸受鋼の場合，1760MPa {180kgf/mm^2} をとれるが，応力集中を考慮した場合,及び経験から更に安全側の値(1170MPa {120kgf/mm^2})をとるのが望ましい。一般的には，通常使用荷重であれば外輪が破壊することはないが，衝撃荷重及び重荷重が加わる場合には外輪破壊強度をチェックする必要がある。

なお，通常使用の応力としては196MPA {20kgf/mm^2}以下であることが望ましい。

$$P=\frac{4\pi}{1+f(\alpha)}\times\frac{D-2h}{h(D-2h_2)^2}\times I\times\sigma$$

ここで

$$f(\alpha)=\frac{(\pi-\alpha)\sin\alpha-(1+\cos\alpha)}{2\cos\alpha}$$

$$\alpha=\frac{\pi}{Z}\ (\text{rad.})$$

P：破壊荷重（N）
I：外輪断面二次モーメント（mm^4）
Z：ころ数
σ＝破壊応力（MPa）
D，h，h_2：**図7**参照（mm）とする。

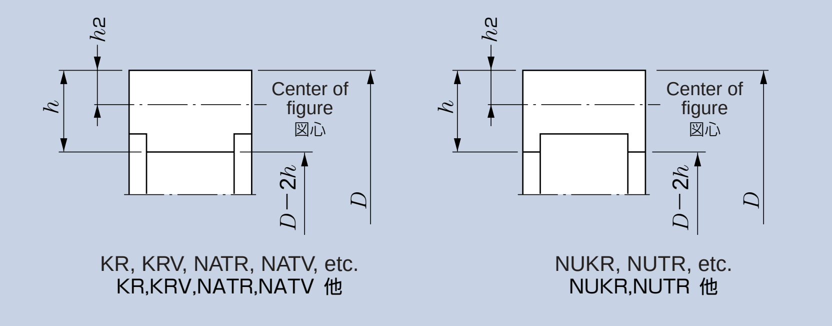

Fig. 7

Cam Follower Stud Strength

If a load Fr is exerted on the midpoint of the outer ring as illustrated in **Fig. 8**, a bending moment $F_r \times \ell$ occurs, and a bending stress σ_1 (considered to be a tensile stress) occurs on the stud surface. Furthermore, since the stud itself is mounted to the machine side with a nut, a tensile stress σ_2 resulting from a thread tightening force also occurs. The stud strength can be evaluated by comparing the sum of the tensile stresses ($\sigma_1 + \sigma_2$) with the allowable stress s of the stud material.

$$\sigma_1 + \sigma_2 < \sigma$$

$$\sigma_1 = \frac{F_r \cdot \ell}{Z}$$

F_r : Max. radial load

Z : Shaft cross-section intersecting point A factor

$\sigma_2 ≒ 98$MPa {10kgf/mm²}

Tensile stress resulting from max. tightening torque specified in dimension table

σ : Allowable stress of the material

The following value is determined from the results of the flex test:

Allowable stress for application of static bending stress:

$\sigma = 1372$MPa {140kgf/mm²}

Allowable stress for application of repeated bending stress (in one direction):

$\sigma = 784$MPa {80kgf/mm²}

Allowable stress for application of repeated bending stress (in both directions):

$\sigma = 392$MPa {40kgf/mm²}

therefore

$$F_r < \frac{Z}{\ell}(\sigma - \sigma_2)$$

カムフォロアのスタッド強度

図8のように外輪中央に荷重F_rが作用する場合，曲げモーメント$F_r \cdot \ell$が生じ，スタッド表面には曲げ応力σ_1（引張応力と考える）が発生する。さらにスタッド自体は，機械本体にナットで締付けられて設置されるため，ねじ締付けによる引張応力σ_2も生じる。この引張応力の和（$\sigma_1 + \sigma_2$）と，材料の許容応力σとの比較からスタッド強度の検討ができる。

$$\sigma_1 + \sigma_2 < \sigma$$

$$\sigma_1 = \frac{F_r \cdot \ell}{Z}$$

F_r：最大ラジアル荷重

Z ：点Aを通る軸断面係数

$\sigma_2 ≒ 98$MPa {10kgf/mm²}

寸法表に記している締付け最大トルクによる引張応力

σ：材料の許容応力

材料の繰り返し曲げ試験の結果から次の値をとる。

静的曲げ応力を受ける場合

$\sigma = 1372$MPa {140kgf/mm²}

繰り返し曲げ応力を受ける場合（片振り）

$\sigma = 784$MPa {80kgf/mm²}

繰り返し曲げ応力を受ける場合（両振り）

$\sigma = 392$MPa {40kgf/mm²}

したがって

$$F_r < \frac{Z}{\ell}(\sigma - \sigma_2)$$

Roller Followers
(Yoke-Type Track Rollers)
ローラフォロア（ヨーク形トラックローラ）

CONTENTS

Construction and Characteristics

NTN roller followers are track rollers each comprise a thick-walled outer ring encompassing integral rollers. Roller followers are designed to operate with outer rings rolling on the track.

Because it is run in direct contact with the track, the outer ring is designed with a thick wall capable of withstanding an impact load.

The outside surface of the outer ring is either spherical or cylindrical in shape. A spherical outer ring can effectively withstand edge loads that result from mounting error.

Because the cylindrical outer ring is in contact with a larger area of the associated track surface, the contact surface pressure is decreased. Thus, this type of outer ring can bear a larger load compared with spherical outer rings and can be used even if the hardness of the associated track surface is low.

NTN roller followers can be categorized into caged and full-complement roller types. With the caged type, the rollers are guided by the cage, making this type suitable for high-speed applications.

The full-complement roller type, by contrast, has an increased load rating, making it suitable for high-load applications (low-speed operation). The double-row cylindrical roller types (NUTR and NUTW types) can bear a even higher load.

In addition to unsealed configurations, **NTN** roller followers are available in with either rubber seals or labyrinth seals (shield plates). Roller followers with seals and full-complement roller-type roller followers are prelubricated with standard grease (lithium soap grease).

構造と特徴

NTNローラフォロアは，肉厚の外輪にころを組込んだトラッククローラで，軌道（トラック）上を外輪が転がり運動する。

外輪は，直接トラックに接触させて使用するため，肉厚の外輪として衝撃荷重にも有効な設計にしている。

外輪外径は球面と円筒面があり，球面外輪は取付誤差によるエッジロード緩和に有効である。

また，円筒外輪は相手トラック面との接触面積が大きいので，接触面圧が軽減され球面外輪に比べ大きな荷重や相手トラック面の硬度が低い場合でも使用できる。

NTNローラフォロアは，保持器付き形と総ころ形とがあり，保持器付き形は保持器によってころが案内されるため，高速回転での使用に適している。

また，総ころ形は保持器付き形に比べ定格荷重が大きく高荷重（低速運転）での用途に適しており，複列円筒ころ形（NUTR形，NUTW形）はさらに高荷重を負荷することができる。

NTNローラフォロアは，シールなしの他にシールあり，ラビリンスシール（シールド板）付きの形式が用意されており，シール付き及び総ころ形は標準グリース（リチウム石けん基グリース）が封入されている。

Bearing Tolerances

The dimensional accuracies and form accuracies of the bearing bore dia. (d), cylinder outside diameter (D), outer ring width (C) and inner ring width (B) for **NAB2** and **NA22** types, as well as the running accuracy of bearing assemblies, are summarized in **Table 12** on page 93 (JIS Class 0). The allowable deviations of the assembled bearing width of the inner ring (B) and spherical OD (D), as well as roller inscribed diameter (F_W) of the **RNAB2 type** and the **RNA22 type**, are found in the associated dimension tables.

軸受の精度

軸受の内径（d），円筒面外径（D），外輪幅（C）及び**NAB2形**，**NA22形**の内輪幅（B）の寸法精度，形状精度及び回転精度は，93ページの**表12**に示す（JIS 0級）。内輪組立幅（B），球面外径（D）及び**RNAB2形**，**RNA22形**のころ内接円径（F_W）の寸法許容差は寸法表に示している。

Fits and Radial Clearances

The tolerance class of the shaft relative to a bearing with an inner ring is g6 (h6). When the shaft is used as a track surface (**RNAB2 type** and **RNA22 type**), the tolerance class of the shaft is k5 (k6). The outer ring is usually not built into the housing.

はめあいとラジアルすきま

内輪付き軸受に対する軸の公差域クラスはg6（h6），軸を直接軌道面とする場合（**RNAB2形**，**RNA22形**）には軸の公差域クラスk5（k6）とする。外輪は，一般にハウジングに組込まれることはない。

Installation

(1) The face height at the roller follower mounting location must be greater than the dimension "e" specified in the dimension table (**Fig. 10**). The chamfer of the stud mounting hole must be minimal (approx. 0.5 × 45°) so that the side face of side plate is firmly seated on the inner ring.

取付け関係

（1）ローラフォロアの取付け部における側面高さは，寸法表記載の"e"寸法より大きくとる（**図10**）。取付けの面取りは，なるべく小さくし（0.5×45°程度），内輪と側板の側面を正確に当てるようにする。

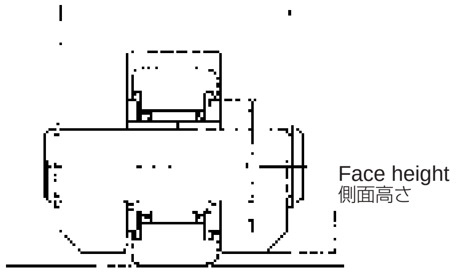

Fig.10

(2) When installing the roller follower, ensure that the lubrication hole on the inner ring is situated in the no-load area (the side not subjected to loading) (**Fig. 11**). Positioning the lubrication hole in the load area may reduce the life of the roller follower.

（2）ローラフォロアを取付ける場合は，内輪の油穴位置は非負荷域（荷重を受けない側）に取付ける（**図11**）。
油穴が負荷域にあると，短寿命の原因となる。

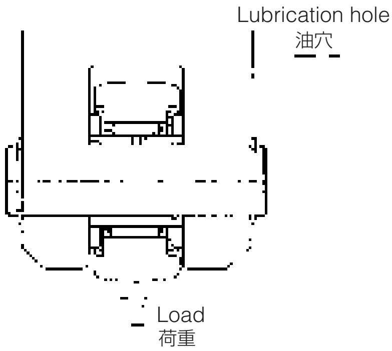

Fig.11

NTN roller followers are normally installed in a cantilever configuration. For this reason, an increasingly loose fit resulting from extended use of the roller follower may result in an uneven load being exerted on the bearing. To ensure reliable operation of the equipment, continually monitor any looseness in the bearing fit.

NTNローラフォロアを片持ちで取付けた場合，継続使用によるはめあいのゆるみの影響で不均一な荷重（片当り）が軸受に作用する場合があります。設備安定稼動のため，はめあいのゆるみには十分な注意が必要です。

(3) The **NA··22LL** and **RNA22** types are separable types, and their outer ring is guided by a flange or thrust washer mounted on the shaft (pin). For this reason, the guide surface must be machined to a fine finish, and burrs must be removed to ensure the smoothness of the surface. If the guide surface is not hardened, the guideway must have the dimension A indicated in **Fig. 12**. If the guide surface is hardened, the width of the guideway may be somewhat smaller than dimension A.
When assembling this type of bearing, take care to ensure that the seal does not roll up or become damaged.

(3) NA··22LL，RNA22形は分離形で軸（ピン）にフランジまたはスラストワッシャを取付けて外輪が案内されるため，案内面は旋削仕上げより良好な仕上げ面とし，バリなどを除去し滑らかな面とする。また案内面が硬化していない場合は**図12**に示すA寸法で案内しなければならない。表面硬化されているときはこれより若干小さくても使用できる。

この軸受の組立時にはシールのリップがまくれないように，また傷を付けないように注意して取扱うことが必要である。

$A \geqq \frac{1}{2}(D+e)$

For dimensions D and e, refer to the dimension table.
D及びe寸法は寸法表参照

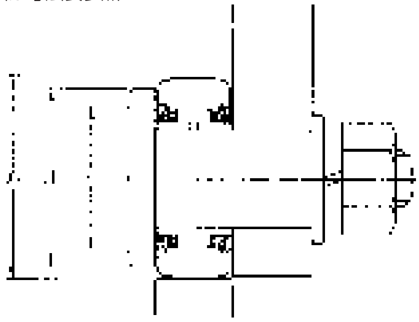

Fig.12

Lubrication

Bearings with synthetic rubber seals (suffix LL) as well as full-complement roller-type bearings are prelubricated with lithium soap grease and can operate in a temperature range of -20˚C to 100˚C. If a grease with better low-temperature characteristics is required for continuous operation below 0˚C, contact **NTN**.

Grease is fed into the bearing through the lubrication hole on the inner ring. When installing the bearing, ensure that the lubrication hole is opposite the area where load is applied.

For full-complement roller-type bearings lacking a cage (**NATV**, **NACV**, **NUTR** and **NUTW types**), relubrication with grease must be repeated more frequently.

Products having a cage but lacking a seal are not prelubricated with grease. If you require a prelubricated type, contact **NTN**.

潤滑

合成ゴムシールを装着した形式（接尾記号：LL）及び総ころ形にはリチウム石けん基のグリースが封入されていて，−20〜+100℃の温度範囲で使用できる。なお，常時0℃以下の場合には，低温特性に優れたグリースの封入品使用を推奨しますので，**NTN**に御照会ください。

軸受内部への潤滑剤の供給又は補給は，内輪に設けた油穴より行う。油穴の位置が非負荷域になるように取付ける。(NAB2形には油穴は設けてありません。)

保持器をもたない総ころ形のNATV形，NACV形，NUTR形及びNUTW形では，グリース補給間隔を短くする必要がある。

保持器付き形でシールなし品にはグリースは封入されておりません。封入品が必要な場合は**NTN**へ御照会ください。

Lubrication is also required between the outer surfaces of the bearing and the track. If lubrication is inadequate, the bearing may wear prematurely.

軸受の外輪外径面と軌道（トラック）間にも潤滑が必要です。潤滑されていないと，軸受の損傷が早期に発生する場合があります。

Track Load Capacity

The maximum allowable static radial load exerted on the contact surfaces between the roller and track is known as "track load capacity". Track load capacity values relative to a HRC40 track hardness are listed in the dimension table. If the hardness of the track is not HRC40, correct for the track load capacity using the correction factor G specified in **Table 8** on page 14.

トラック負荷容量

トラックローラとトラック（軌道）の接触面で静的に許容できる最大ラジアル荷重をトラック負荷容量と呼び，トラック（軌道）の硬さがHRC40のときの値を寸法表に記載している。HRC40と異なる場合は14ページ，**表8**に示す補正係数Gを用いて補正する。

Raceway Surface Accuracy

The raceway dimensional accuracy, profile accuracy and surface roughness of shaft must be equivalent to the raceway accuracy of bearing itself. **Table 10** shows the specified surface accuracy and surface roughness of the shaft raceway.

軌道面の精度

軸の外径面を軌道面として用いるときは，軌道面の寸法精度，形状精度及び表面粗さは，軸受の軌道面と同等でなければならない。軌道面の精度及び表面粗さの仕様を**表10**に示す。

Table 10 Recommended raceway surface accuracy
軌道面の精度（推奨）

Characteristic item 特　性	Shaft 軸
Dimensional accuracy 寸法精度	IT5
Roundness 真円度 (max)（最大） cylindricality 円筒度	IT3
Shoulder perpendicularity (max) 肩の直角度（最大）	IT3
Axial run-out アキシアル振れ (max)（最大） Thrust bearing スラスト軸受	IT5
Surface roughness 表面粗さ	0.2a

Material and Hardness of Raceway Surface

When the outer surface of a shaft (hollowed) is used as raceway, it must be hardened to HRC58 to 64 for sufficient load capacity. The materials shown in **Table 11** can be used if properly heat treated.

When the steel is surface-hardened by carburizing or carbonitriding, the effective hardened layer depth as defined by the applicable JIS standard is the depth at which the hardness decreases to HV550. The approximate minimum value for the effective hardened layer depth is expressed in the following formula.

$$E_{ht\ \min} \geqq 0.8 D_w (0.1 + 0.002 D_w)$$

Where

$E_{ht\ \min}$: Minimum effective hardened layer depth mm

D_w : Roller diameter mm

軌道に用いる材料と硬さ

軸の外径面を軌道面として用いるときは，十分な負荷容量を得るため，表面硬さをHRC58～64にする必要があり，**表11**に示す材料などに適切な熱処理をして使用する。

鋼を浸炭焼入れ又は浸炭浸窒焼入れにより表面硬化させるとき，JISでは表面からHV550までの深さを有効硬化層と定義している。有効硬化層深さの最小値は下記の式にて概略で表わされる。

$$E_{ht\ \min} \geqq 0.8 D_w (0.1 + 0.002 D_w)$$

ここで，

$E_{ht\ \min}$ ：最小有効硬化層深さ　mm

D_w ：ころの直径　mm

Cam Followers & Roller Followers with Solid Grease

ポリルーブカムフォロア・ローラフォロア

Overview 概 要

Solid grease for cam and roller followers is composed principally of a lubricating grease and a polymer. Solid grease has the same properties at normal temperature as ordinary greases before heat treatment. However, when heated and cooled, the polymer solidifies retaining a larger portion of the lubricant. Even when severe vibration or a large centrifugal force is exerted on the bearing, the solid grease rarely leaks. Solid grease greatly contributes to longer bearing life, prevents bearing contamination, and improves the work environment.

ポリルーブカムフォロア，ローラフォロアに封入される熱固化型グリースは潤滑グリースと樹脂を主成分とする潤滑剤です。常温ではグリース状ですが一度加熱冷却する（熱処理と呼ぶ）と，多量の潤滑剤が保持されたまま硬化する。ポリルーブは熱処理後固形となるため，強い振動や大きな遠心力が作用する場合でも潤滑剤が漏れにくく，軸受の長寿命，軸受まわりの汚染防止，環境改善に貢献する。

Features 特 徴

1. Low grease leakage

Once heated and cooled, the grease/polymer mixture solidifies, ensuring that a large portion of the lubricant is retained in the bearing. As heat and centrifugal force act on the bearing, the lubricant is gradually supplied to the rolling contact surface while rarely leaking from the bearing. Therefore, unlike ordinary greases, solid grease allows a clean work environment.

2. Good lubricity

Even when severe vibration or centrifugal force is exerted on a cam or roller follower, the lubricant rarely leaks ensuring good lubrication. Also, solid grease does not readily emulsify and flow out even if water enters the bearing.

3. Sealing effect

Solid grease functions as a shield against the ingress of foreign matter, providing a moderately effective dust prevention effect. However, the solid grease alone is not a secure sealant. Therefore, **NTN** recommends that a bearing with a seal be selected and/or a seal be provided around the bearing.

（1）潤滑剤の漏れが少ない

ポリルーブは熱処理後固形となるため，内部に多量の潤滑剤を保持する。この潤滑剤が，軸受の発熱，遠心力により，転動面に徐々に供給されるため潤滑剤の漏れが少なくなる。このため一般の潤滑グリースに比べ周囲環境への汚染防止となる。

（2）潤滑特性が良い

強い振動や大きな遠心力がカムフォロア，ローラフォロアに作用する場合でも，潤滑剤が漏れにくく，また，ポリルーブは固形であるため水分の浸入があっても乳化して流出しにくいので，潤滑特性が一般の潤滑グリースに比べ優れている。

（3）シール効果

ポリルーブは外部からの浸入物（水分，塵埃など）に対して防壁となり一定の防塵効果が期待できるが，密封装置としては十分ではないのでシール付き軸受の選定，更には軸受まわりにシール設計の検討を推奨します。

Available Cam Followers & Roller Followers 製作対応可能形番

- Cam followers and roller followers with a cage (excluding those with a synthetic resin cage)
- Full-complement roller type (cylindrical roller) cam followers and roller followers (Not available for full-complement needle roller types)

■保持器付カムフォロア，ローラフォロア（ただし，保持器が合成樹脂製のものは除く）
■総ころ形（円筒ころ）カムフォロア，ローラフォロア（針状ころの総ころ形は対応不可）

■Nomenclature for cam followers & roller followers with solid grease
ポリルーブカムフォロア，ローラフォロアの呼び番号例

KR 30 LL DO H ／LP03

- Lubricant code (/LP03: solid grease) 潤滑記号（／LP03：ポリルーブ）
- Supplementary suffix (H: Stud head with hexagonal socket) 補助記号（H：スタッド頭部六角穴付き）
- Bearing ring code (DO: Oil hole. No oil groove.) 軌道輪形状記号（DO：油穴，油溝なし）
- Seal & shield code シール・シールド記号
- Dimension code 寸法記号
- Type code 形式記号

NATR 8 LL ／LP03

- Lubricant code (/LP03: solid grease) 潤滑記号（／LP03：ポリルーブ）
- Seal & shield code シール・シールド記号
- Dimension code 寸法記号
- Type code 形式記号

Usage Precautions 使用上の注意点

1. Allowable temperature range

The allowable temperature range of cam and roller followers with solid grease is –20°C to 80°C. The maximum allowable temperature for continuous long-term operation is 60°C. The operating temperature must be closely monitored.

2. Limiting speed

Cam and roller followers with the solid grease can be used for $F_w \times n$ values up to 30,000.

$F_w \times n$ value: (F_w =roller inscribed circle diameter [mm]) ×(n=operating speed [rpm])

3. Minimum required load

To ensure the rolling elements turn without slipping, provide a load of at least 1% of the basic dynamic load rating.

4. Other precautions

Solid grease serves to shield against the ingress of foreign matter. However, solid grease alone is not an effective sealant. Therefore, **NTN** recommends that a bearing with a seal be selected. Water ingress can lead to corrosion problems. **NTN** recommends that the customer assess the probability for rust.

Do not use cam and roller followers with the solid grease in an environment where organic solvents (acetone, petroleum benzene, kerosene, etc.) are present.

(1) 許容温度範囲

許容温度範囲は－20℃～80℃であるが，連続長時間使用の場合は60℃以下のため使用温度には充分注意ください。

(2) 許容回転速度

カムフォロア，ローラフォロアは $F_w \cdot n$ 値＝30 000以下でご使用ください。

$F_w \cdot n$ 値：
(F_w＝ころ内接円径寸法［mm］)×(n＝使用回転速度［r／min］)

(3) 最小必要荷重

転動体が滑ることなく回転させるために少なくとも基本動定格荷重の1％程度の荷重が必要です。

(4) その他

ポリルーブは，外部からの浸入物に対して防壁となりますが密封装置としては充分ではないのでシール付型番を推奨します。また水分に対しては別途錆の問題も懸念されますので一度評価いただくことを推奨します。

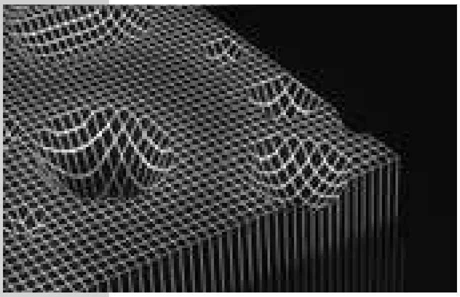
他方，有機溶剤（アセトン，石油ベンジン，白灯油など）のかかる条件下では使用できないので注意ください。

Typical Applications 使用用途例

- Printing presses : Cam mechanism
- Press machine : Guide rollers
- Food processing machinery, packaging machinery : Conveyors, guide rollers
- Steel production machinery : Guide rollers
- Car manufacturing lines : Conveyors, guide rollers
- Logistics & material handling equipment : Guide rollers
- Textile machinery : Cam mechanism
- Medical equipment : Guide rollers, etc.

- 印刷機械：カム機構部
- プレス機械：ガイドローラ
- 食品，包装機械：コンベア部，ガイドローラ
- 鉄鋼設備：ガイドローラ
- 自動車製造ライン：コンベア，ガイドローラ
- 物揚・送搬機：ガイドローラ
- 繊維機械（織機）：カム機構
- 医療機器：ガイドローラ　等々

HL Outer Ring Roller Followers
HL外輪ローラフォロア



Overview 概要

The HL (High Lubrication) surface contains countless dimples ranging in size from 10 µm to 100 µm. These “micro oil pots” are scattered in a random pattern. **NTN** has often incorporated this type of surface on bearing rollers and is now using it on the outside surface on the outer rings of cam followers and roller followers to provide improved lubrication.

HL（High Lublicationの略）表面は，大きさ数10μm程度の凹部（マイクロオイルポット）を無数にランダムにつけた表面で，一般的にはころ単品での実績が多くありますが，カムフォロア，ローラフォロア外輪外径面に適用するものです。

Available Roller Followers 製作対応形番

Cam followers and roller followers whose outer rings do not exceed 30 mm in outside diameter can be manufactured with HL. For outside diameters exceeding 30 mm, contact **NTN**.

カムフォロア，ローラフォロアの外輪外径がφ30mm以下の形番を原則とする。なお外径がφ30mmを超えてのご要望の場合，**NTN**へ御照会ください。

Features 特徴

Micro oil pots scattered in a random pattern on the HL surface to create a high capacity for oil film formation. This feature is especially useful in difficult-to-lubricate areas where peeling problems tend to occur. This helps to resist wear and extend the service life.

HL表面は微小凹部を無数にランダムにつけたことにより油膜形成能力が高く，特にピーリング損傷などの発生しやすい潤滑条件の厳しい使用箇所で実力を発揮し，摩耗対策や長寿命効果が期待できる。

Applications 用途

- Engine roller rocker (see photo above)
- Cam roller on automatic weaving machine
- Cam roller on printing press

- エンジンローラロッカ（上図参照下さい）
- 自動織機 カムローラ
- 印刷機械 カムローラ

Stainless Steel Cam Followers

ステンレス製カムフォロア

Overview 概 要

NTN cam followers are used in a wide variety of applications due to their ease of installation and reliable performance.

Recently, customer have requested improved corrosion resistance in wet or humid environments. To meet this need, **NTN has** developed stainless steel cam followers.

カムフォロアはその取り扱いの容易さより，幅広い用途で使用され耐食性のニーズに対し，材質をステンレス鋼で製作したものです。

Available Cam Followers 製作対応形番

1. 2F-○○○○ : The outer ring, stud, side plate, and included hexagonal nut are made of stainless steel. All externally visible areas are made of stainless steel in this cost-effective cam follower.
2. F-○○○○ : All the components other than the seal are made of stainless steel. (○○○○—represents the cam follower number in the dimension tables).

（1）2F−○○○○：外輪，スタッド，側板，添付六角ナットがステンレス材である。外から見える部分はすべてステンレス製で，経済的なカムフォロアである。

（2）F−○○○○：全部品（シール除く）ステンレス材での設計，製作品である。（○○○○—前述寸法表のカムフォロア名称がつく。）

Features 特 徴

This type of cam follower resists corrosion in severe operating conditions such as very wet environments with high humidity; rugged and wet terrain; and environments where water intermittently contaminates the area around the bearing. Under these conditions, the service life of stainless steel cam followers exceeds that of standard cam followers.

水蒸気をはじめ湿気の多い雰囲気，水たまり不整地用途，水が軸受及び軸受まわりに間欠的にかかる条件等に対して，一定の防錆効果が期待でき，標準カムフォロアに比べて長寿命である。

Usage Precautions 使用上の注意

1. Before employing a stainless steel cam follower in order to counteract corrosion (especially when caused by water), assess the corrosion resistance and expected life of the intended stainless steel cam follower.
2. The calculated fatigue life of stainless steel cam followers is approximately 50% that of standard cam followers. However, corrosion rather than fatigue is generally the limiting factor in bearing life in corrosive environments.

（1）錆対策でのステンレス製カムフォロア選定（特に水分がらみ案件）にあたっては本格採用前に防錆効果と寿命についてご確認ください。

（2）材質がステンレス製より，計算寿命は標準品の概ね50%である。

Cam Followers & Roller Followers with Grooved Outer Rings
外輪溝付きカムフォロア・ローラフォロア

Cam follower with grooved outer ring (above) and roller followers with various types of grooved outer rings (right)
外輪溝付きカムフォロア（写真上）と
各種外輪溝付きローラフォロア（写真右）

Overview 概 要

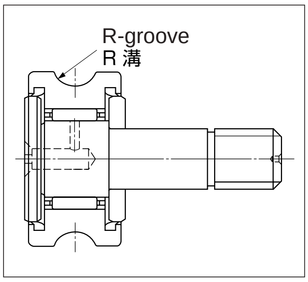
This type of bearing has an outer ring whose outside surface is grooved to conform to the shape of its mating surface. It is used as a guide roller. The available grooves include R-grooves and V-grooves. The installation procedure is identical to that of standard bearings.

外輪外径に，相手材の形状に合わせた溝を設けた軸受で，ガイドローラとして使用する。溝形状は，R形状やV形状などの加工が可能であり，取付け要領などは標準軸受と同一である。

Features 特 徴

- The R-groove can be finished to a mirror surface for specific applications.
  (The standard finish is produced by turning and lapping.)
- The basic design is identical to that of standard cam followers.
- Installation is simple.
- This product can be an economical alternative to purchasing a bearing and separate housing to serve as a guide roller.

(1) R溝形状は用途に応じて鏡面仕上げも可能である。
(一般：旋削→ラップ仕上げ)
(2) 基本設計はカムフォロア標準に準じている。
(3) 取付けが容易である。
(4) 直動装置のガイドローラとしても使用でき，経済的な場合もある。

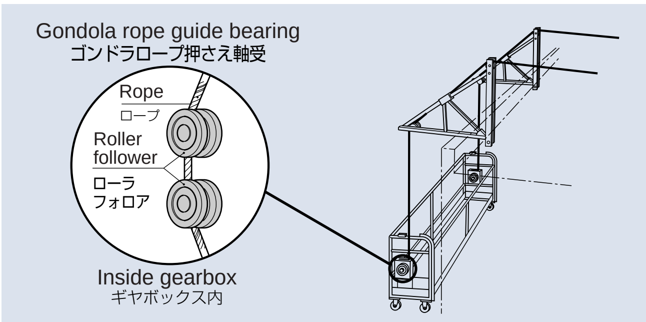


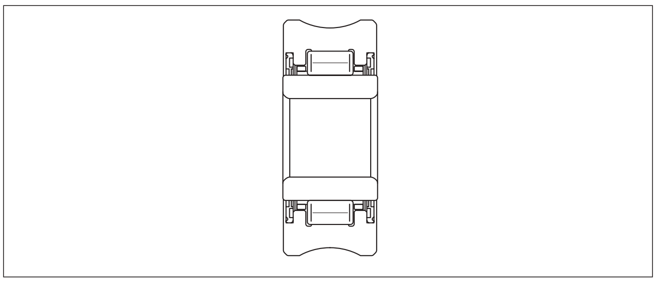
Applications 用 途

- Guide rollers for steel wire and steel pipe
- Straightening rollers
- Rope gripper on gondola hoisting device for window washing

- 鋼線及び鋼管のガイドローラ
- 矯正ローラ
- ビル清掃ゴンドラ巻上げ機ロープつかみ装置など

Typical applications of bearings with solid grease ポリルーブ軸受応用例





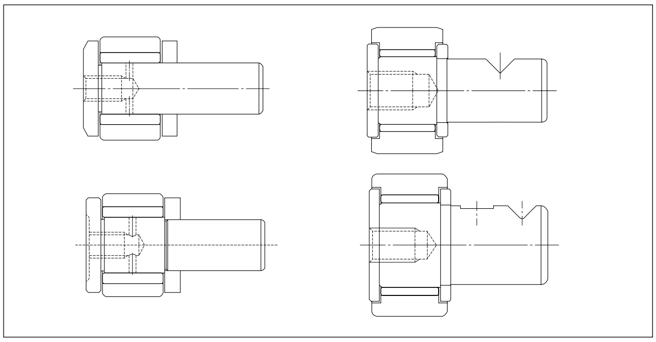
Index Cam Followers

インデックス用カムフォロア

Overview 概 要

Automatic machinery performs various operations including intermittent motion, oscillation and continuous rotation at high speed and with a high degree of precision. Index cam followers are used in the roller cam mechanism of the drives in such machinery.

自動機は間欠，揺動，連続回転など多様な動きを高精度でかつ高速で行うが，この駆動部のローラカム機構にカムフォロアが使用される。



index cam followers
インデックスカムフォロアの形状例

Features 特 徴

1. A rigid outer ring and stud can be housed in limited space.
2. This full-complement roller design offers greater load capacity and longer life than caged cam followers.
3. The dimensional & running accuracy of this cam follower are higher precision than standard.
4. This cam follower is easily installed by a setscrew.

（1）限られたスペース内で適切な外輪及びスタッド剛性を有する。
（2）総ころ設計のため，保持器付きより負荷容量が大きく長寿命である。
（3）寸法·回転精度が精密級のカムフォロアである。
（4）セットねじにて位置固定をするため，取付けが容易である。

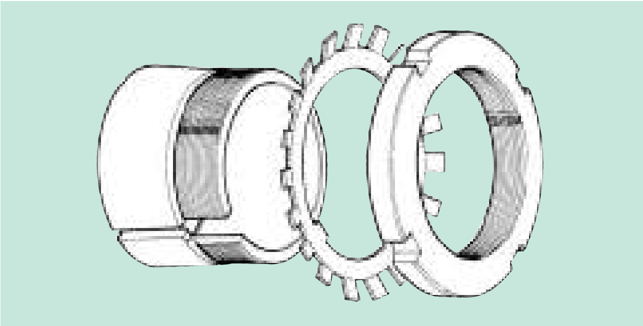
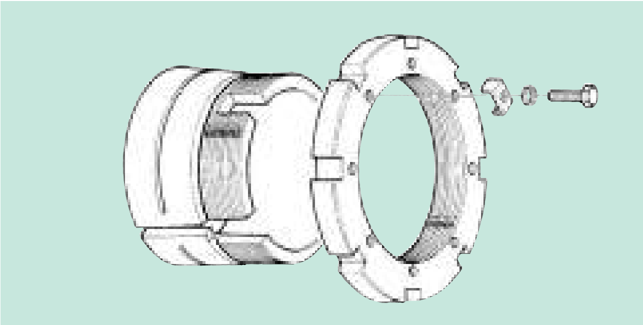
1. Types and Features



Adapters

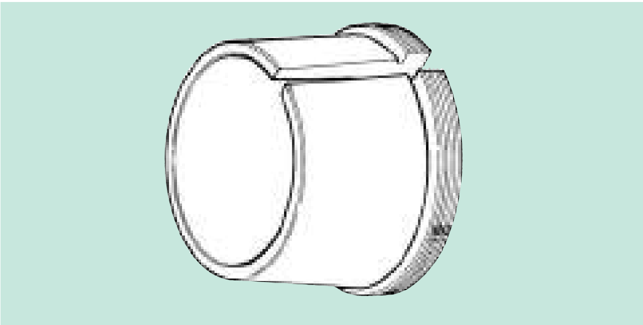
Adapters are made up of adapter sleeves, nuts, and washers or clasps.

These adapters are used to mount tapered bore bearings easily on specific positions of shafts.



Hydraulic Adapters

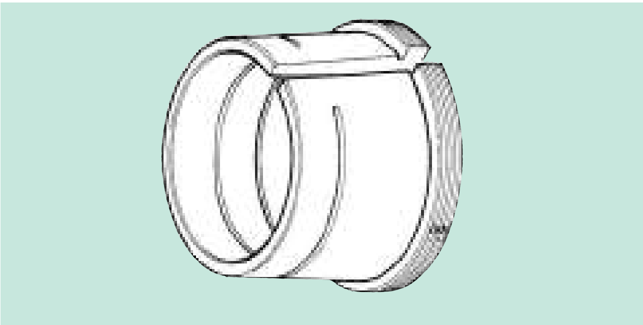
Hydraulic adapters feature an oil inlet and oil groove in the sleeve, which make installation to and removal from the shaft easier, particularly with large bearing.



Withdrawal Sleeves

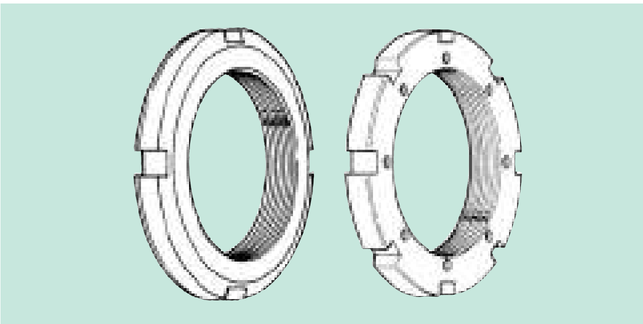
Withdrawal sleeves are used to mount tapered bore bearings on shafts.

Withdrawal sleeve nuts are used when removing bearing from shafts.



Hydraulic Withdrawal Sleeves

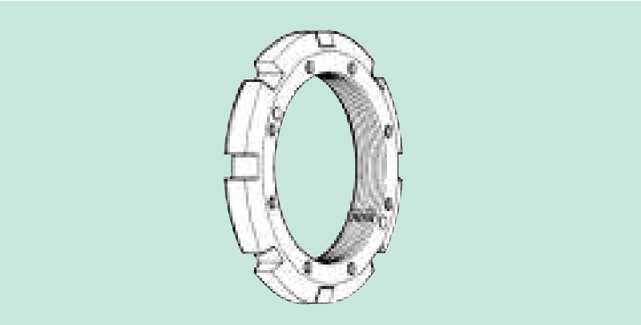
Hydraulic withdrawal sleeves feature an oil inlet and oil groove in the sleeve, which make mounting to the shaft and disassembly easier, particularly with large bearings.



Locknuts, Nuts

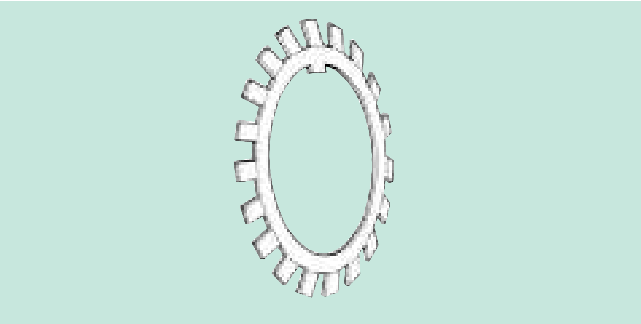
Locknuts are used with adapters, withdrawal sleeves and shafts.

Nuts are used with withdrawal sleeves and shafts.



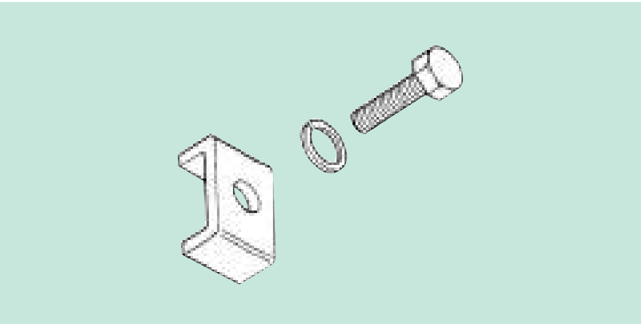
Hydraulic Sleeve Nuts

Hydraulic sleeve nuts feature threaded bolt holes for mounting and withdrawal, and holes for passing through hydraulic hoses.



Lockwashers

Lockwashers are used to stop nuts from rotating.

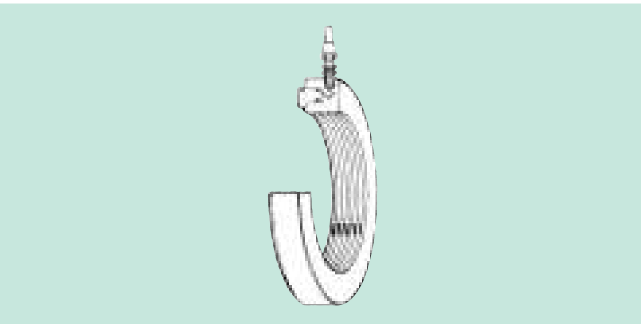


Lockplates

Lockplates are used to stop large nuts from rotating.

Protective Plates

Protective plates are inserted between the hydraulic sleeve and hydraulic sleeve nut during installation, and protects the sleeve from damage.



Hydraulic Nuts

(Mounting & Dismounting Tools for Rolling Bearings)

Using hydraulic nuts for mounting and dismounting bearings prevents excessive force being applied, so as to avoid damage to shafts and bearings. The force applied is also uniform for more efficient work.

2. Details of Special Hydraulic Sleeve

Hydraulic Adapters

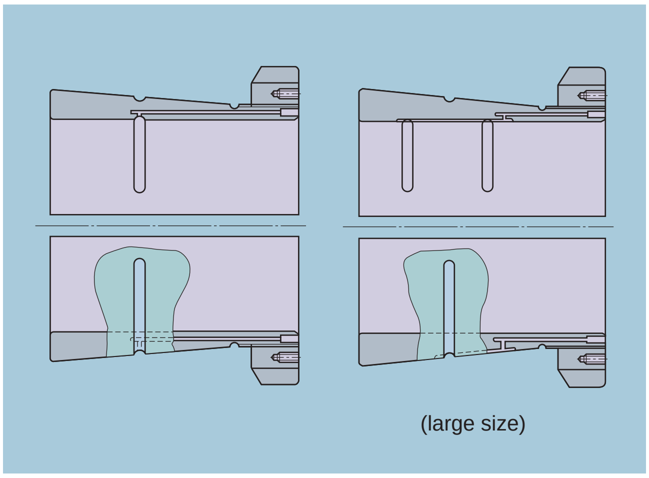


Fig. 1 HFW type

Features an oil groove added to the bore surface of the standard type hydraulic adapter sleeve to suit applications where movement is required between the shaft and adapter.

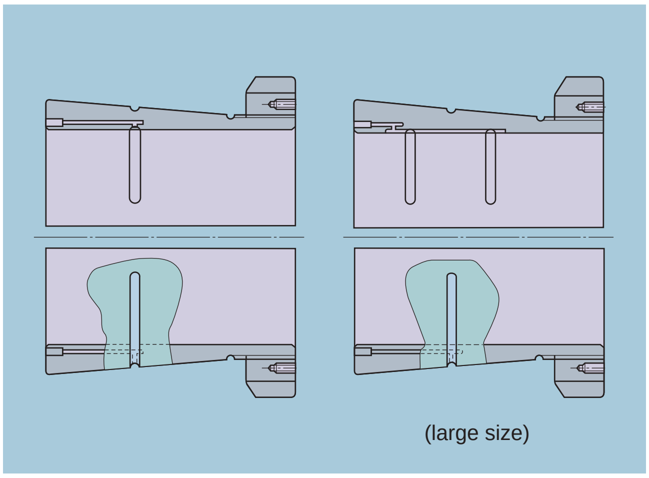

Fig. 2 HBW type

Similar to the HFW type adapter but with the oil inlet on the large side of the adapter sleeve.

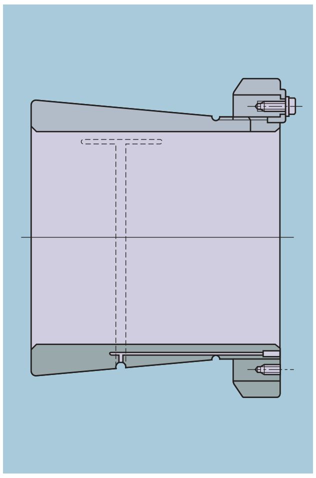

Fig. 3 HFT type

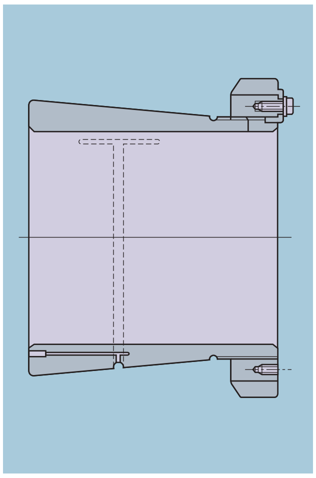

Fig. 4 HBT type

Features an oil groove added to the hydraulic adapter sleeve in an axial direction, which makes installation and removal of bearings even easier.

The HFT type features the HBT type oil inlet added to the large side of the adapter sleeve.

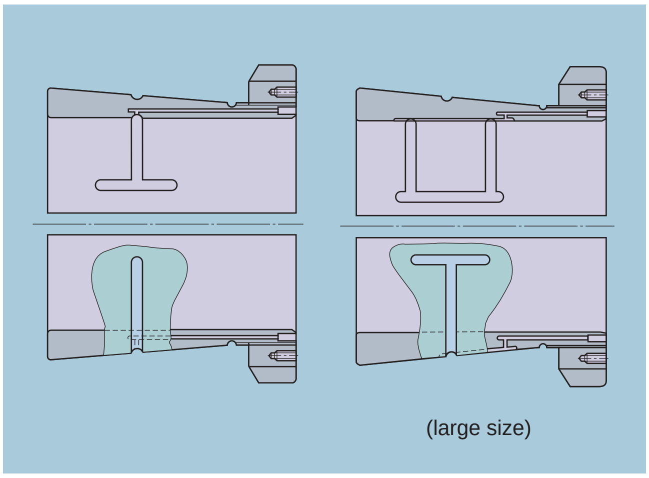

Fig. 5 HFWT type

Feature the HFW type with oil groove added in the axial direction.

Hydraulic Withdrawal Sleeves

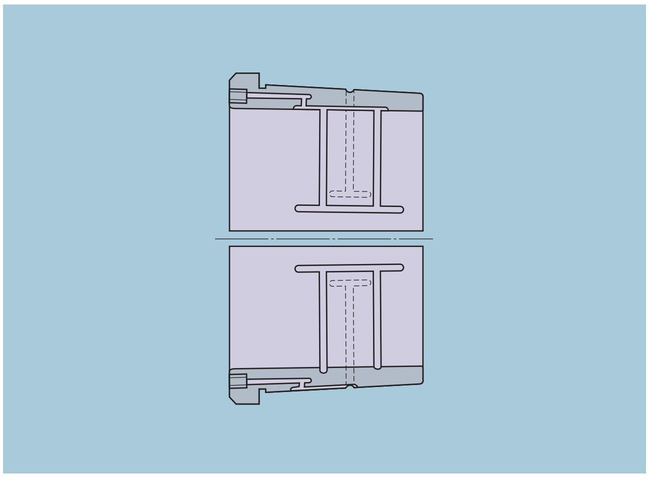

Fig. 6 HT type

Features an oil groove added to the hydraulic withdrawal sleeve in an axial direction, which makes installation and removal of bearings even easier.

Note : 1) Adapter sleeves with the code "**X**" appended after the adapter number indicate a narrow slit type adapter sleeves which use washers with straight inner tabs.
2) Part number **HE311XY** uses a different thread pitch than standard due to the wall thickness of the adapter sleeve thread, and has the suffix code **Y** for identification purposes.

❶ Standard thread shapes and dimensions of the part numbers **AH3120** to **AHY3138** are as per JIS B0205-1 and JIS B 0205-4 (general purpose metric screw threads).
Standard thread shapes and dimensions of the part numbers **AH3138** to **AHX3196** are as per JIS B 0216 (metric trapezoidal screw threads).
❷ B_4 dimensions indicate reference dimensions before attachment of withdrawal sleeves.
❸ d_{T1} dimensions indicate that it does not meet JIS B 1552 standards.
❹ B_G dimensions indicate that it does not meet JIS B 1552 standards.
❺ Indicates nut to be used at time of disassembly.

❶ Standard thread shapes and dimensions of the part numbers **AH3934** to **AH3938** are as per JIS B 0205-1 and JIS B 0205-4 (general purpose metric screw threads). Standard thread shapes and dimensions of the part numbers **AH3940** to **AH3996** are as per JIS B 0216 (metric trapezoidal screw threads).
❷ B_4 dimensions indicate reference dimensions before attachment of withdrawal sleeves.
❸ d_{T1} dimensions indicate that it does not meet JIS B 1552 standards.
❹ B_G dimensions indicate that it does not meet JIS B 1552 standards.
❺ Indicates nut to be used at time of disassembly.
Note : The part number for hydraulic adapters has the suffix at the end. E.g. **AH3944H**

Note : 1) Locknut series **ANL** is used for adapter series **H(HE)30**.
2) The part number for hydraulic sleeve nuts has the suffix at the end. E.g. **ANL44SP**
3) Protective plates applicable to hydraulic sleeve nuts are listed on P52.

Note : 1) Narrow slit type adapter sleeves appended with the code suffix "**X**" after the **H (HE, HS)2** and **HH (HHE, HHS)23** part numbers use straight inner tab washers. Wide slit type adapter sleeves without the suffix code "**X**" after the adapter part number can use either bent inner tab washers istraight inner tab washers.

2) Bent inner tab type of the part number **AW00** and **AW01** indicate that they do not meet JIS B 1554 standards.

AWL100	**AWL100X**	500	550	595	40	491	36	4	25	203	19	2	ANL100

Note : Narrow slit type adapter sleeves appended with the code suffix "**X**" after the **H30** and **H30(E)** numbers use straight inner tab washers.
Wide slit type adapter sleeves without the suffix "**X**" code after the adapter part number can use either bent inner tab washers or straight inner tab washers.

- The values for the allowable limit dimensions above do not include thread shape errors or pitch errors (total cumulative errors). When manufacturing Tr threa the lower limit of the above allowable limit dimensions are to be used where possible for machining.

Note : These values were calculated with class 7e from JIS B 0217 (metric trapezoidal screw threads).

4. Handling

(1) Installation/removal of adapter sleeves using locknuts

Using adapters to mount bearings onto shafts makes installation and positioning easier, while maintaining the appropriate level of holding force needed. Incorrect installation methods may cause damage when running the bearings, so care is re during installation.

Withdrawal sleeves can be handled in the same way as adapters, however the following procedures mainly outline the handling method for adapters.

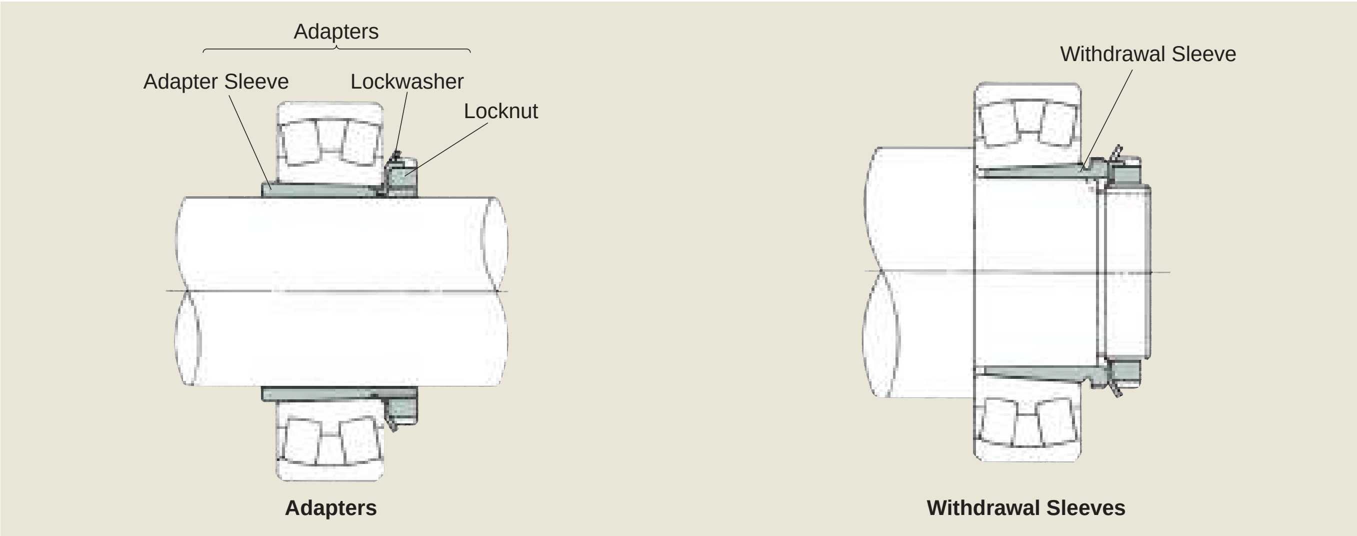

Fig. 1

1. Preparation

(1) Prepare the relevant tools and lubricants required for assembly work (see **Fig. 2**).

Fig. 2

(2) Verify the part number of the bearings and adapters being installed, and check that the adapter and dimensions are suitable for the shaft diameter.

(3) Clean the shafts that the adapters will be installed on.Check that the shaft diameter measurements are within the specified appropriate tolerance (see **Fig. 3**).

(4) Adapters have rust inhibitor applied to the surface. After removing the adapters from their packaging, wipe clean any oil using a clean cloth soaked in kerosene.

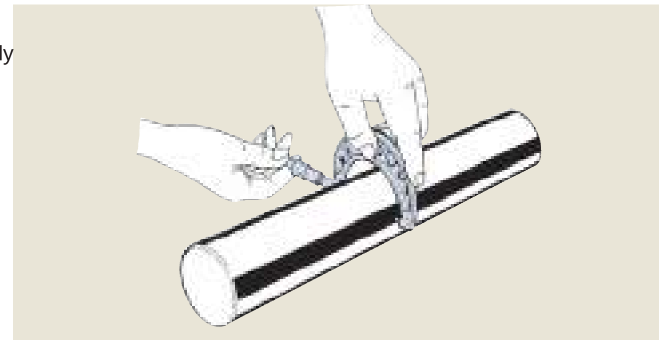

Fig. 3

(5) To prevent scoring and other damage caused by high surface pressures when fastening components, first apply lubricant containing molybdenum dioxide or extreme-pressure gear oil to the tapered surfaces of sleeves, threads, the side of nuts and other surfaces. Take care that no oil is applied between the shaft and adapter during this step.

If components are assembled immediately after cleaning and then fastened, the poor lubrication between the bearing and shaft contact surfaces as well as fastening threads may result in insufficient fastening caused by scoring on thread peaks before the specified level of fastening is achieved.

2. Installation

(1) When fitting the adapter to the shaft, use the appropriate wedge to open the split section of the adapter sleeve to make it easier to fit it to the shaft (see **Fig. 4**).

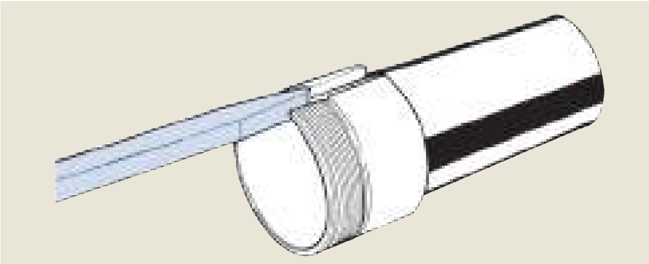

Fig. 4

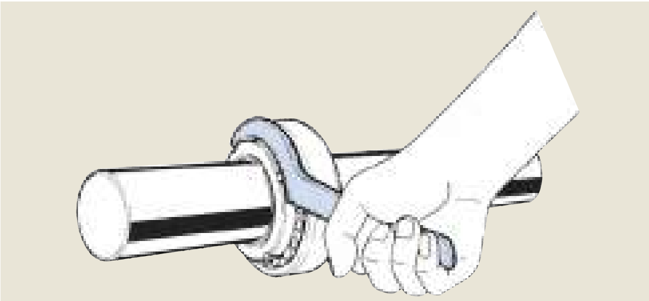

Fig. 5

(2) Using the hook spanner shown in **Fig. 5** makes it convenient to fasten the nut. If a hook spanner is not available, fasten the nut by aligning the end of a suitably sized rod with the notch in the nut and tapping with a hammer, as shown in **Fig 6**. Hitting it wildly may cause deformation of the notch in the nut or burrs to be formed, damaging the bearing.
