Large nuts require a high fastening torque, and washers can be easily damaged when fastening nuts with washers still attached. Remove the washer first before fastening the nut. When using this method, remove the nut after the specified level of fastening has been achieved, fit the washer and fasten the nut again to its original position.

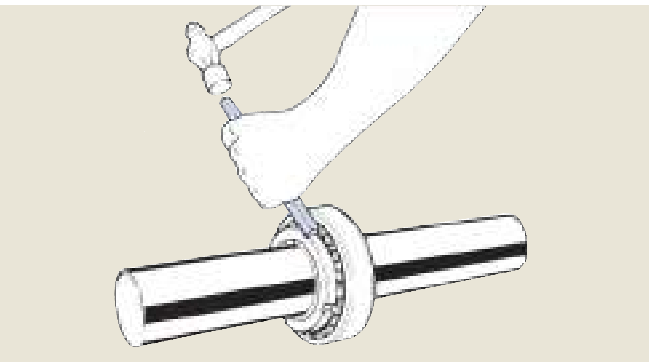

Fig. 6

(3) To check that the specified level of fastening has been achieved, measure how much the bearing radial internal clearance has changed before and after fastening (see **Fig. 7**), or measure the relative amount of axial movement between the adapter and bearing.

See the relevant "Ball and Roller Bearings Catalog" CAT. No. 2202 for details of these values.

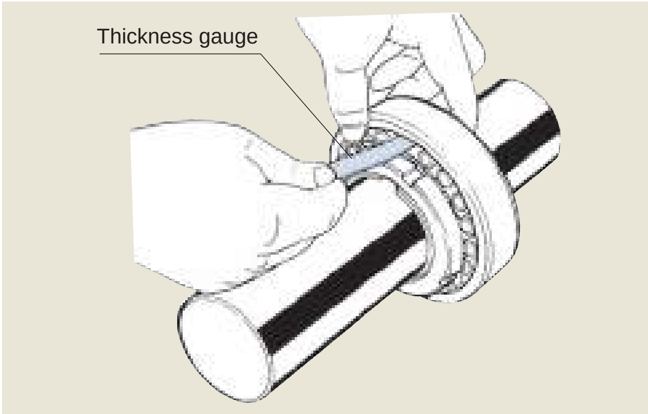

Fig. 7

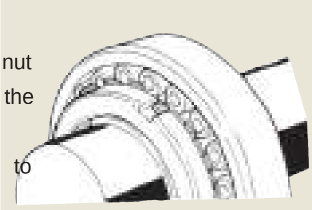
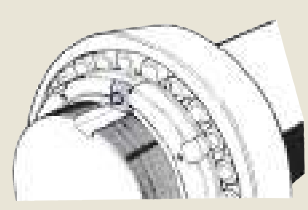
(4) After fastening, always check that the specified level of fastening above has been achieved, and bend the washer securing tab into the notch in the nut (**Fig. 8**). For large nuts, use a clasp to secure the nut (see **Fig. 9**). When doing so, do not turn the nut backwards so that the tab is aligned with the notch.



Secured with washer tab

Fig. 8



Secured with clasp

Fig. 9

3. Removal

For adapters, first lift the washer tab that is bent into the notch in the nut, and use a hook spanner or rod and hammer to turn the nut to 3 times to loosen it. With the nut loosened, the bearing can be removed easily by aligning the rod against the side of the nut and pushing in the direction for removing the sleeve (see **Fig. 10**).

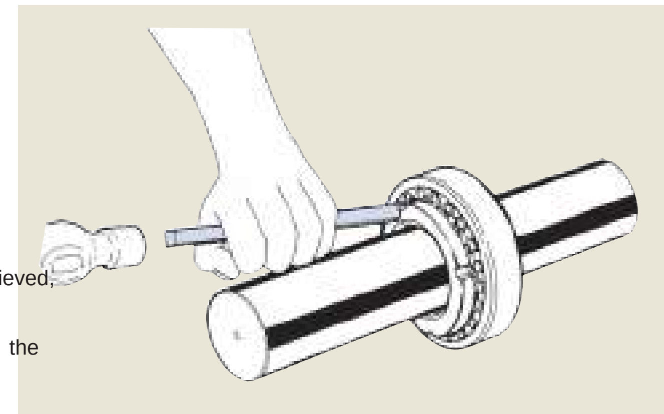


Fig. 10

(2) Installation/removal of bearings using hydraulic sleeves

Using the pressure from a hydraulic pump when installing tapered bore bearings makes it easy to install bearings without applying exc force. When using either a hydraulic adapter or hydraulic withdrawal sleeves, the eight fastening bolts are to be fastened with equal for Hydraulic adapters are to be handled in the same way as hydraulic withdrawal sleeves, however the following procedures mainly outlin handling method for hydraulic withdrawal sleeves.

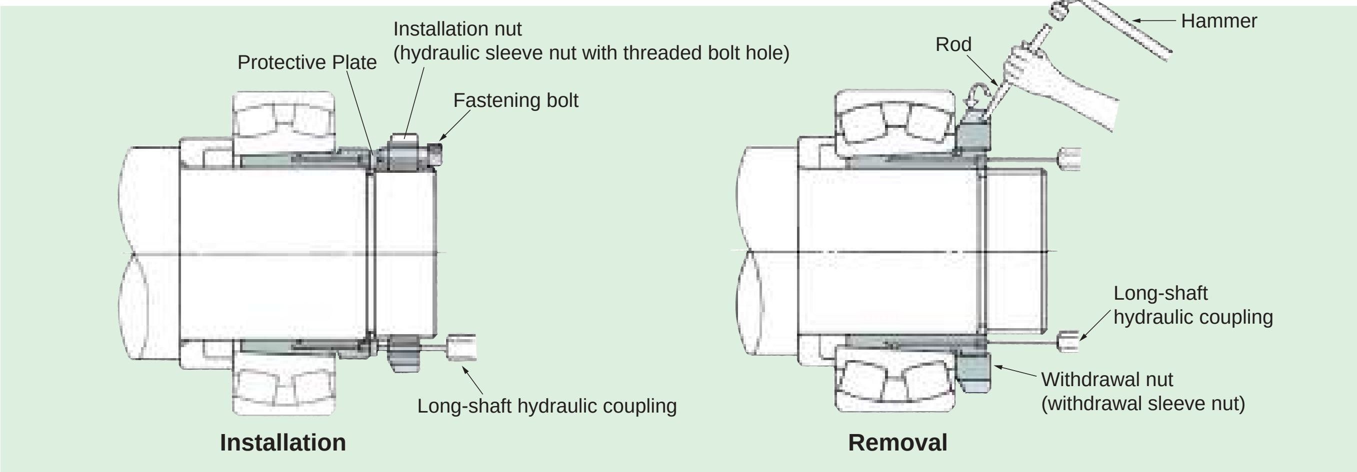

Fig. 11

1. Installation

(1) Preparation

In addition to the items shown in **Fig. 2** on P. 55, prepare a hydraulic pump, hydraulic sleeve nut, protective plate and hexagonal bolts (see **Fig. 12** and **13**).

Set the hydraulic pump to a pressure between 35 to 70 MPa (350 to 700 kgf/cm², 5000 to 10000 lbf/in²) to suit the specific application.

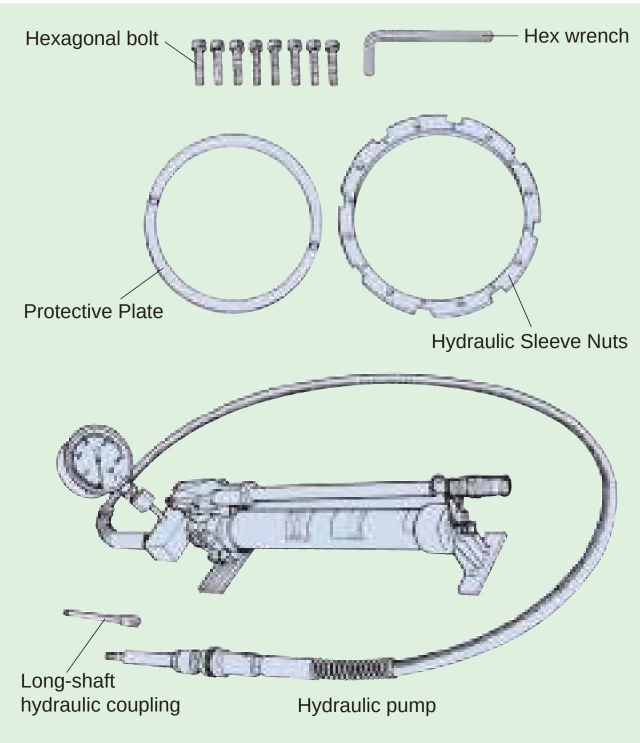

Fig. 12

(2) Install the bearing and hydraulic withdrawal sleeve (see **Fig. 13**).
Next, set protective plates that suit the shaft they are being mounted to, to both ends of the hydraulic withdrawal sleeve.

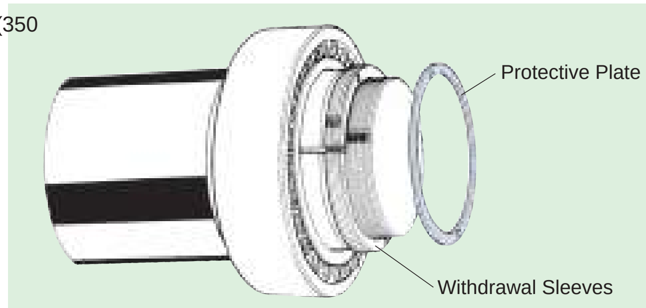

Fig. 13

(3) Prepare an installation nut that suits the shaft it is being mounted to. First assemble fastening bolts (×8) that have been applied with molybdenum dioxide to the installation nut (see **Fig. 14**).

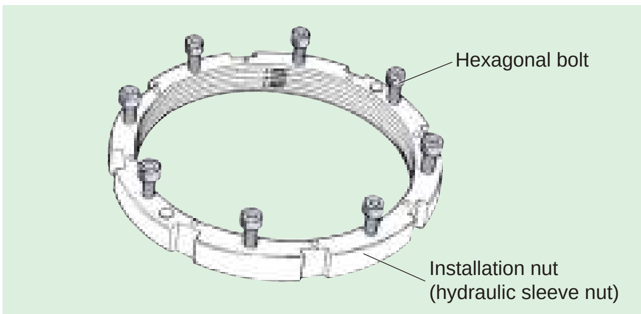

Fig. 14

(4) Check that the holes in the hydraulic withdrawal sleeve, protective plate and installation nut are aligned along the same shaft, and connect the hose from the long-shaft hydraulic coupling and hydraulic pump (see **Fig. 15**).

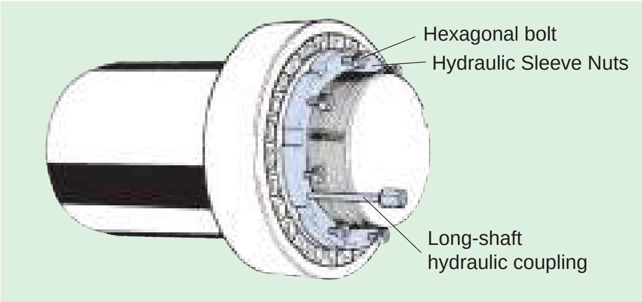

Fig. 15

(5) Increase the hydraulic pump pressure while tightening the fastening bolts with a spanner and measure the bearing radial internal clearance with a thickness gauge, and tighten the bolts evenly until reaching the specified mounted clearance (see **Fig. 16**).
Remove the nut and bolt, and secure with the specified washer or clasp.

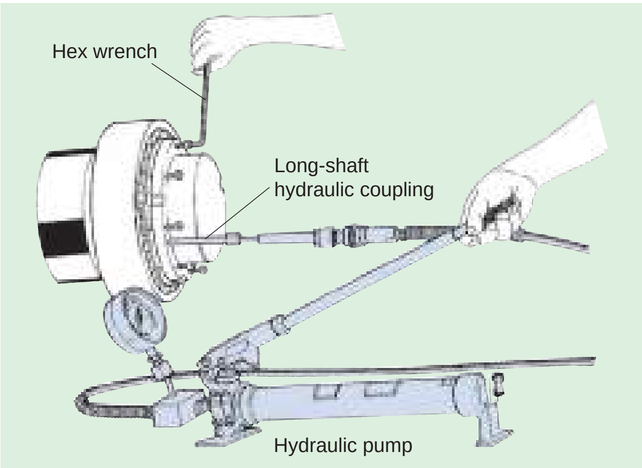

Fig. 16

2. Removal

(1) Preparation

Prepare a hydraulic pump, long-shaft hydraulic coupling, withdrawal nut, rod and hammer (see **Fig. 17**).

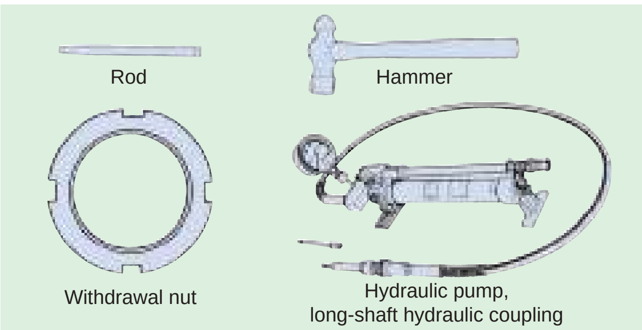

Fig. 17

(2) Prepare a withdrawal nut that suits the hydraulic withdrawal sleeve, and install it to the thread of the hydraulic withdrawal sleeve (see **Fig. 18**).

(3) Set the long-shaft hydraulic coupling to the lubrication port at the end of the hydraulic withdrawal sleeve (see **Fig. 19**).

(4) Connect the hose from the hydraulic pump to the long-shaft hydraulic coupling (see **Fig. 19**).

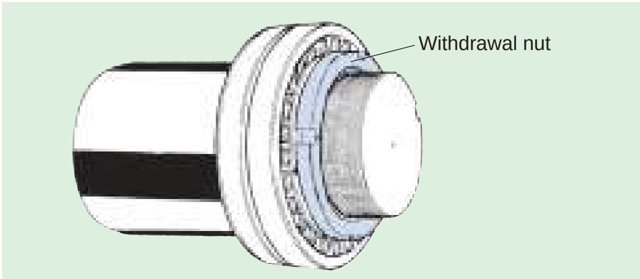

Fig. 18

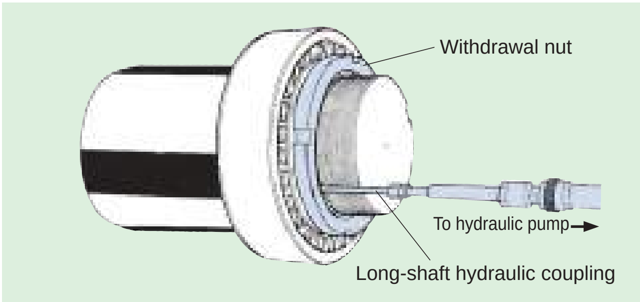

Fig. 19

(5) Turn the withdrawal nut using the pressure from the hydraulic pump, and remove the hydraulic withdrawal sleeve (see **Fig. 20**).

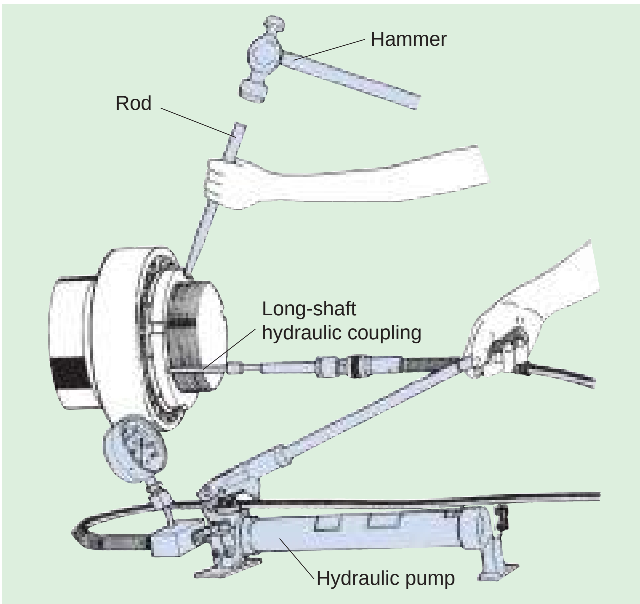

Fig. 20

Tap the four notches in the withdrawal nut using the rod and hammer while applying pressure from the hydraulic pump, and remove the hydraulic withdrawal sleeve.

Example of hydraulic sleeve usage

Bearing installation

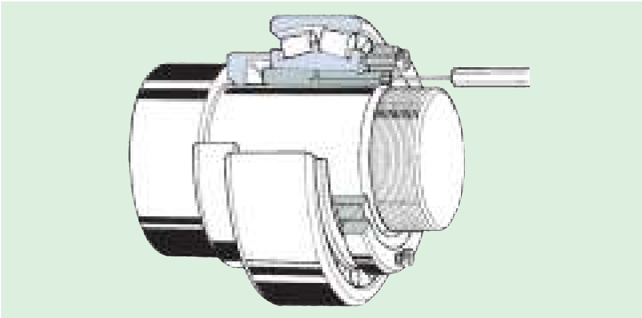

Fig. 21 Hydraulic adapter

Fasten the bolt of the hydraulic sleeve nut and install the bearing.

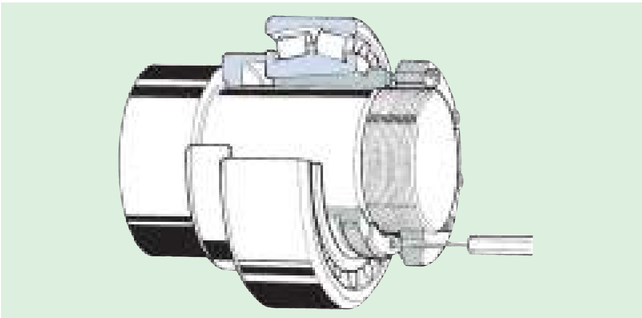

Fig. 22 Hydraulic withdrawal sleeve

Fasten the bolt of the hydraulic sleeve nut and install the bearing through the protective plate.

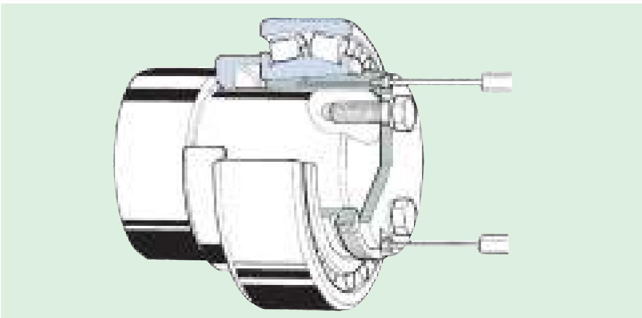

Fig. 23 Hydraulic withdrawal sleeve

Install the bearing through the end plate by fastening the bolt at the end of the shaft.

Bearing removal

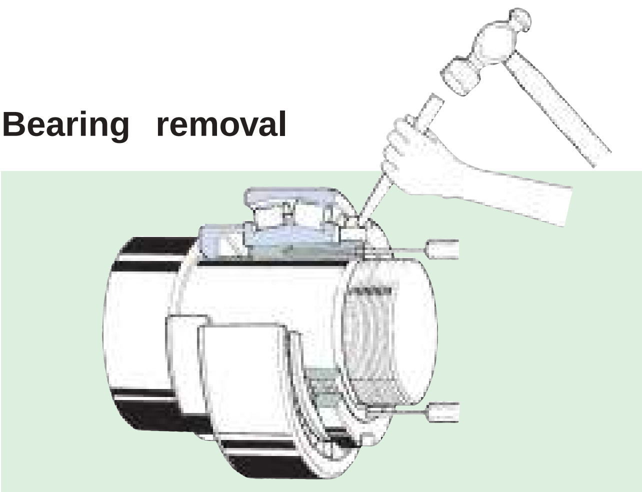

Fig. 24 Hydraulic withdrawal sleeve

Tap the withdrawal sleeve nut with a rod and hammer, and remove the bearing together with the withdrawal sleeve.

(3) Installation/removal of bearings using hydraulic nuts

Installing tapered bore bearings directly onto shafts or using adapters or withdrawal sleeves and removing them from shafts requires higl pressure forces and pulling forces. Using hydraulic nuts prevents excessive force from being applied that would damage shafts and bearin while applying large, equal forces for installation and removal work.

Adapter sleeves are to be handled in the same way as withdrawal sleeves, however the following procedures mainly outline the handlin method for withdrawal sleeves.

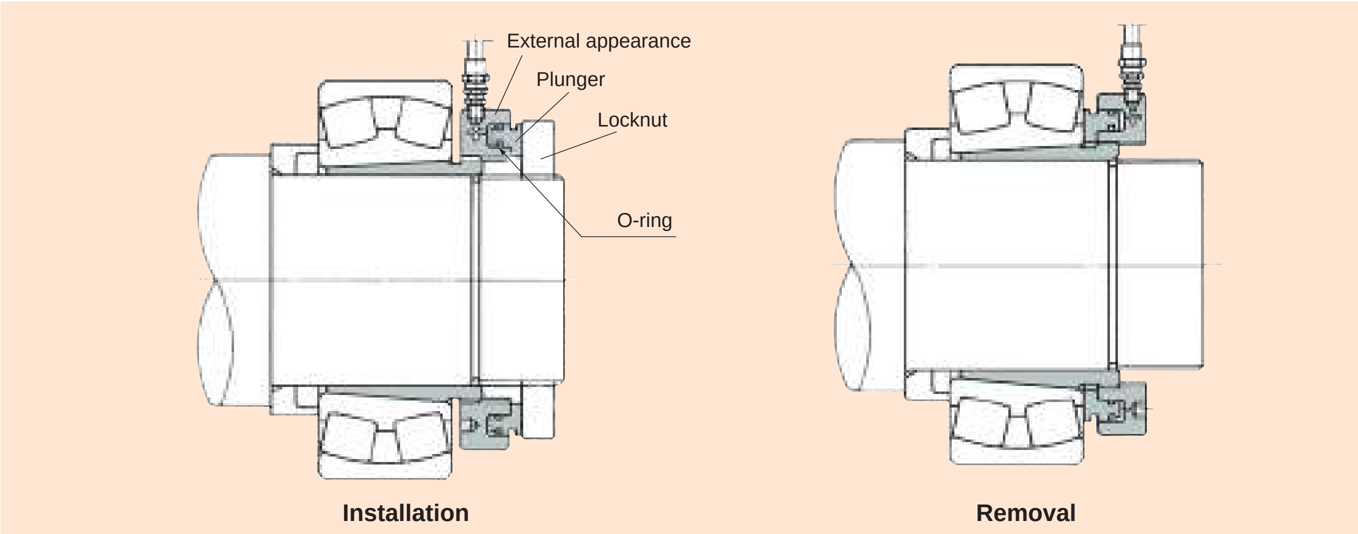

Fig. 25

1. Preparation

Prepare the relevant tools and hydraulic pumps required for assembly and removal work (see **Fig.** P. 55). Other precautions are the same as those listed under 1. Preparation on P. 55.

2. Confirmation

Check each boundary dimension of parts such as bearings, hydraulic nuts, locknuts and withdrawal sleeves (see **Fig. 26**, **27**, **28**).

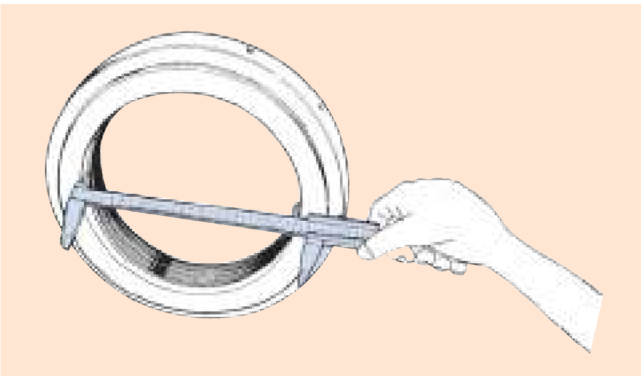

Fig. 26

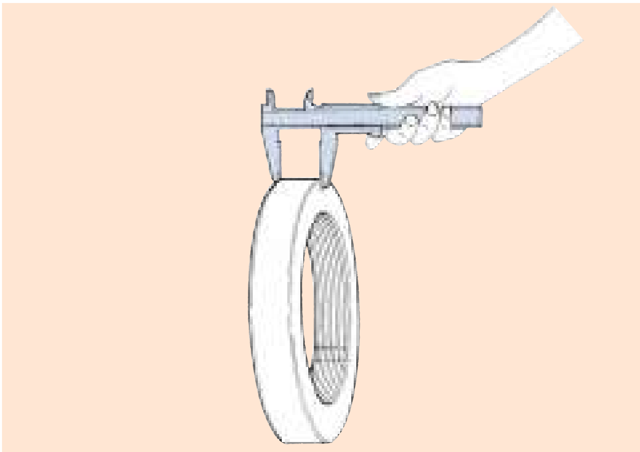

Fig. 27

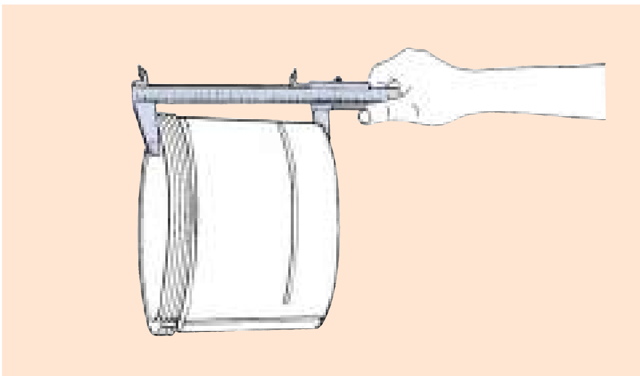

Fig. 28

3. Installation

(1) With the bearing moving free before installation (before fastening), measure the radial internal clearance with a thickness gauge (see **Fig. 29**). Measure the bearing clearance at three or more points around the bearing, and take the average value.

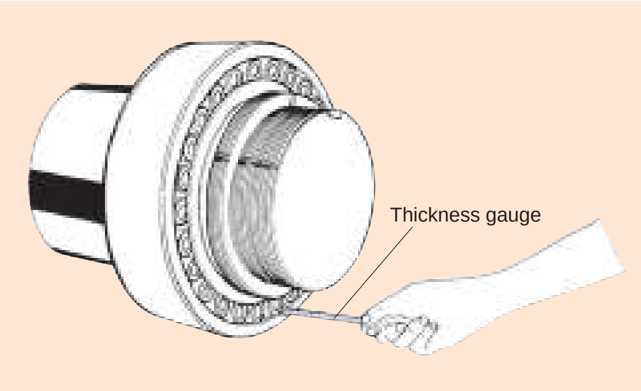

Fig. 29

(2) After installing the hydraulic nut, install a locknut that suits the installation shaft as shown in **Fig. 30**.

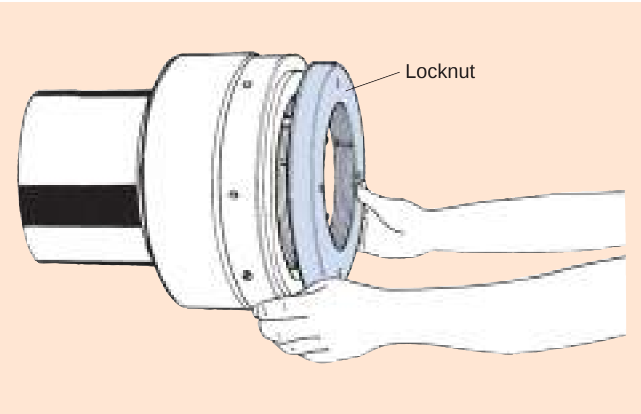

Fig. 30

(3) Connect the hose from the hydraulic pump to the hydraulic nut using a hydraulic coupling (see **Fig. 31**).

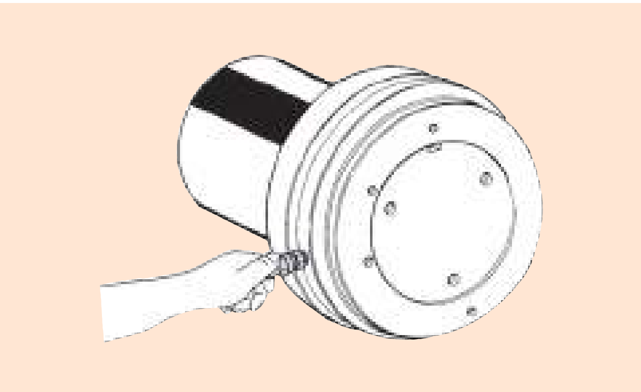

Fig. 31

(4) Measure the bearing radial internal clearance with a thickness gauge, and increase the hydraulic pump pressure until reaching the specified mounted clearance (see **Fig. 32**).

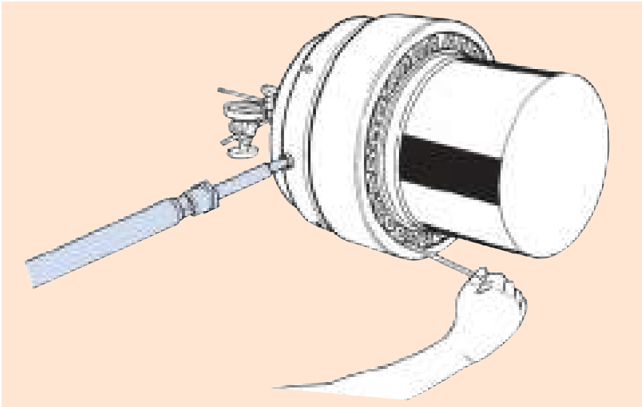

Fig. 32

(5) Remove the locknut and hydraulic nut, set a washer that suits the installation shaft, fasten the shaft nut and bend the washer tab into the notch in the nut to secure it. For large nuts, use a clasp to secure the nut (see **Fig. 33**).

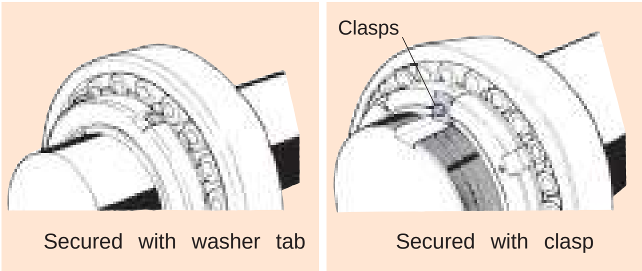

Fig. 33

4. Removal

Install a hydraulic nut to the thread of the withdrawal sleeve, and remove the withdrawal sleeve from the bearing using the hydraulic pump pressure (see **Fig. 34**). When doing so, install the bearing so that it makes contact with the plunger side of the hydraulic nut.

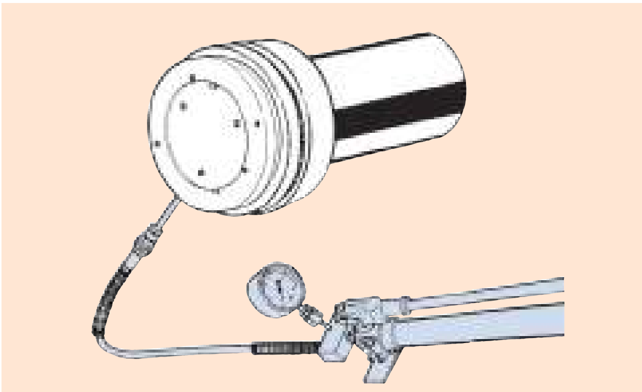

Fig. 34

Example of hydraulic nut usage

Bearing installation

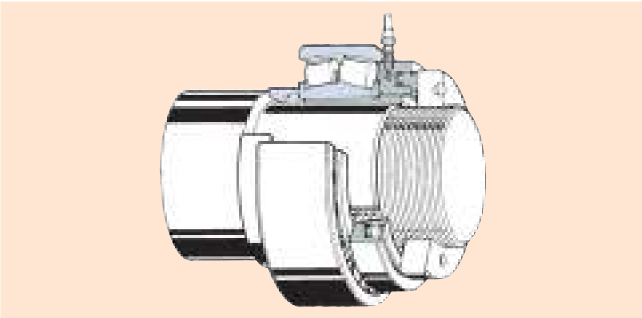

Fig. 35 Using a locknut

Screw the hydraulic nut onto the withdrawal sleeve, turn the locknut on the shaft thread until it makes contact with the plunger, and increase pressure to press the sleeve.

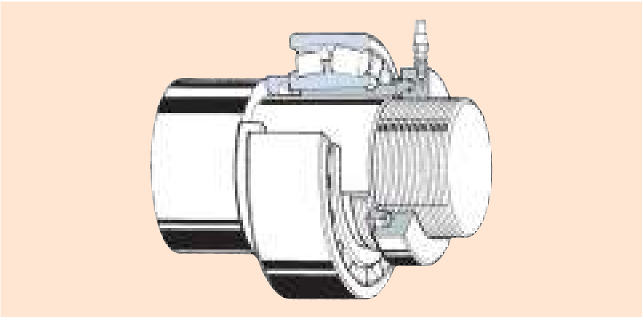

Fig. 36 Using the installation shaft thread

Turn the hydraulic nut on the shaft thread so that the plunger makes contact with the side of the withdrawal sleeve, and increase pressure to press the sleeve.

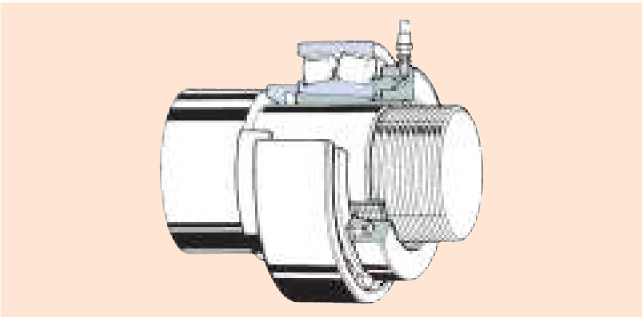

Fig. 37 Using the adapter sleeve thread

Turn the hydraulic nut on the adapter sleeve so that the plunger makes contact with the side of the bearing, and increase pressure to press the bearing.

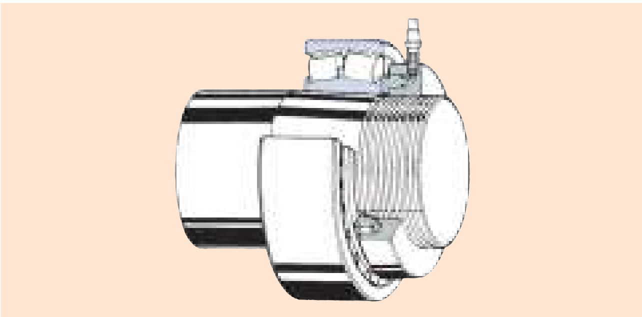

Fig. 38 Using the tapered bearing thread

Turn the hydraulic nut on the shaft thread so that the plunger makes contact with the side of the bearing, and increase pressure to press the bearing.

Bearing removal

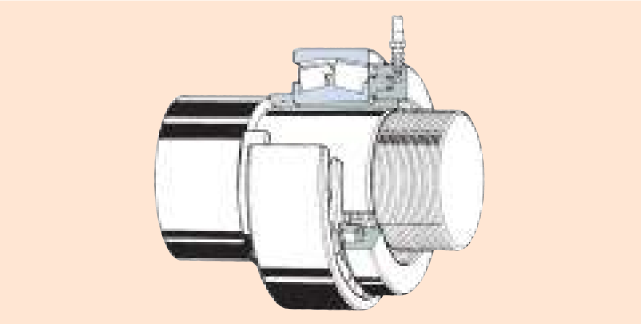

Fig. 39 Using the withdrawal sleeve thread

Turn the hydraulic nut on the withdrawal sleeve so that the plunger makes contact with the side of the bearing, and increase pressure to pull out the withdrawal sleeve.

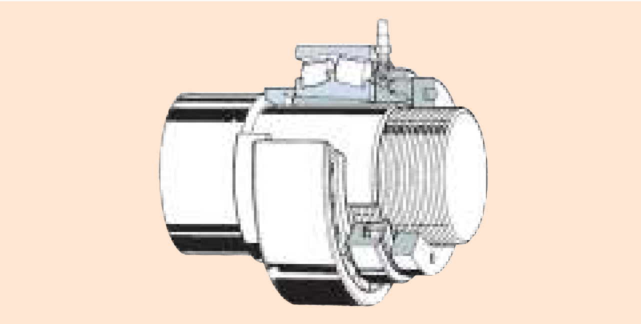

Fig. 40 Using a locknut

Install the hydraulic nut to the adapter sleeve (maintain clearance between the bearing and the side of the hydraulic nut), turn the locknut until it makes contact with the locknut, and increase pressure to press the sleeve..

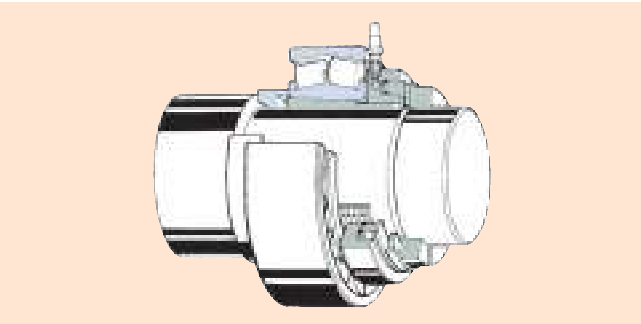

Fig. 41 Using a stop ring

Turn the hydraulic nut on the adapter sleeve (maintain clearance between the bearing and the side of the hydraulic nut), and secure the stop ring with the shaft groove. Increase pressure to press the sleeve through the stop ring.

NTN corporation

Large Size, Long Operating Life Bearing - EA type

CAT. No. 3024/E

NTN Large Size, Long Life Bearings - EA type

A newly developed special heat treatment allows these bearings to ensure longer operating life under severe operating conditions!!

EA bearings have a particularly strong advantage by providing longer operating life due to their improved crack fatigue strength, wear strength and peeling resistance characteristics, especially when the lubricant is contaminated and also when the lubricant is clean. Accordingly, these bearings can be used at steel rolling mills and casting facilities where poor lubrication, vibrations and impact loads often exist. The EA bearings provide advantages due to their compact design, longer operating life, and longer intervals between maintenance and inspections. They can be used also for other applications with heavy loads and severe lubricating conditions such as construction and industrial machines.

1 Performance

(Operating life and strength comparison of EA bearings against standard carburized bearings)

(1) Operating life using lubricant mixed with foreign matter is: More than 5 times.
(2) Operating life using clean lubricant is: More than 2 times.
(3) Peeling strength: 3 times. (Rate of incidence is 1/3.)
(4) Wear strength: 2 times. (Wear rate is 1/2.)
(5) Fret strength: 1.3 times.(Wear rate is about 80%.)
(6) Operating life when fitting stress is high is: 3 times.
(7) Operating life against crack fatigue is: 1.5 times.

2 EA bearings

The analysis of bearing damage over many years confirms that most damages to large size bearings are caused by flaking, which starts from indentations made by foreign particles, from peeling caused by insufficient lubrication, from smearing and from cracks originating from those spots on the surface.

EA bearings are produced by a special heat treating process of carburized steel. This process is especially used for larger size bearings. The heat treatment combines carburization and nitriding. This process is an important achievement which strengthens the surface layer and provides a longer operating life when the damage originates on the surface. (Refer to **Fig.1**) The special heat treatment is applied to tapered roller bearings, cylindrical roller bearings and self-aligning spherical roller bearings. Consult **NTN** Corporation for available bearings. Large bearings are identified by the prefix EA. Small size tapered roller bearings use the prefix ETA.

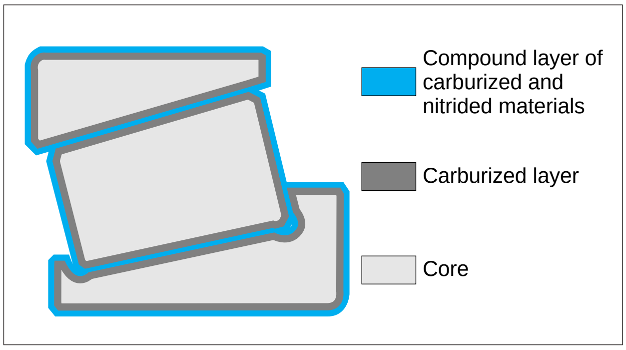

Fig. 1

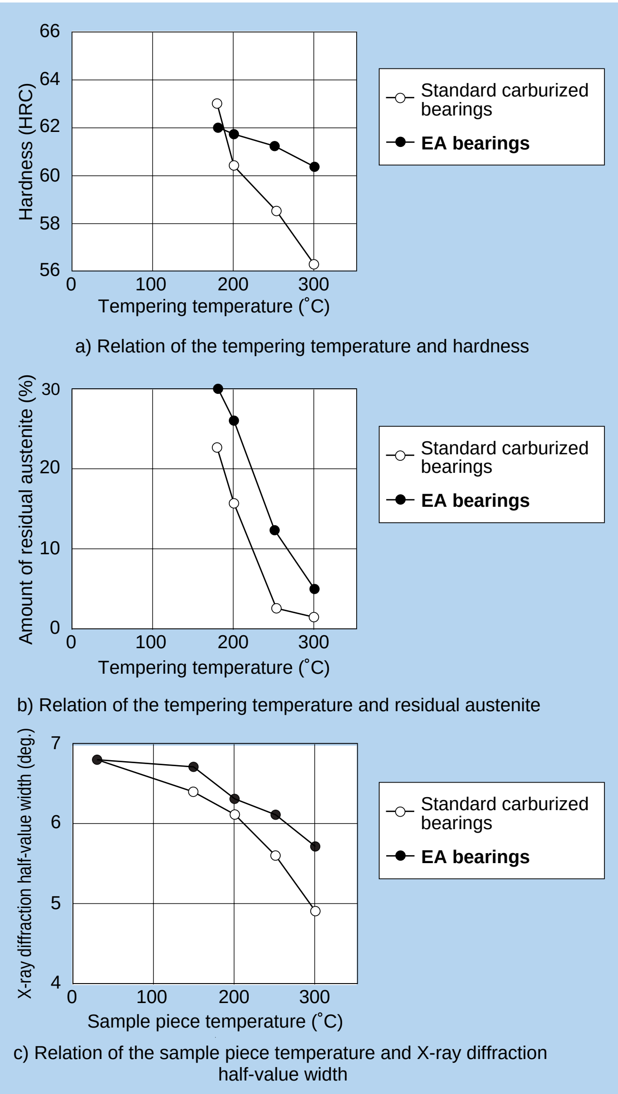
3 Long Operating Life Theory

EA bearings are designed to form the dispersion of proper amounts of residual austenite and carbides in the surface layer through the special heat treating process. This also improves the thermal stability of the structure. Heat is usually generated on the raceway surface due to rolling friction and sheering stress. For standard bearings this may often change the characteristics of the material (i.e. its sheering stress, hardness and microstructure) and cracks may occur due to re-tempering and fatigue. Consequently, the peculiar characteristics of the EA bearing, namely the temper resistance which will not change the material quality due to tempering, and the surface toughness which will resist cracks and elongation, are effective against the types of damage which start from points on the surface. Adequate amounts of residual austenite, obtained by standard carburization, prevent cracks and their growth when through the manufacturing operations the bearing material strengthens and the surface layer becomes tougher, but this material on the surface is unstable when heated. Because of this fact, compounding nitrogen under suitable conditions and by permeating nitrogen, the residual austenite and martensite matrix of EA bearings is heat stabilized. This maintains the material quality while extracting the appropriate amount of carbide to increase the fatigue strength without lowering the crack strength.

Fig.2 shows the change of hardness of the standard carburized bearing and the carburized EA bearing by tempering, the change of residual austenite by tempering and the relation of matrix strength at high temperature measured by X-ray diffraction half-value width. Compared with the standard process, the special heat treatment provides high resistance to re-tempering and stability of residual austenite.

Fig.3 shows the change of the material quality on the bearing race surface when a lubricant mixed with foreign matter is used in the rolling fatigue test. The EA bearings show a longer operating life since their X-ray diffraction half value width (martensite hardness) and the residual austenite on the surface are resistant to change.



a) Relation of the tempering temperature and hardness

b) Relation of the tempering temperature and residual austenite

c) Relation of the sample piece temperature and X-ray diffraction half-value width

Fig.2 Material stability comparison for standard carburized bearings with EA bearings

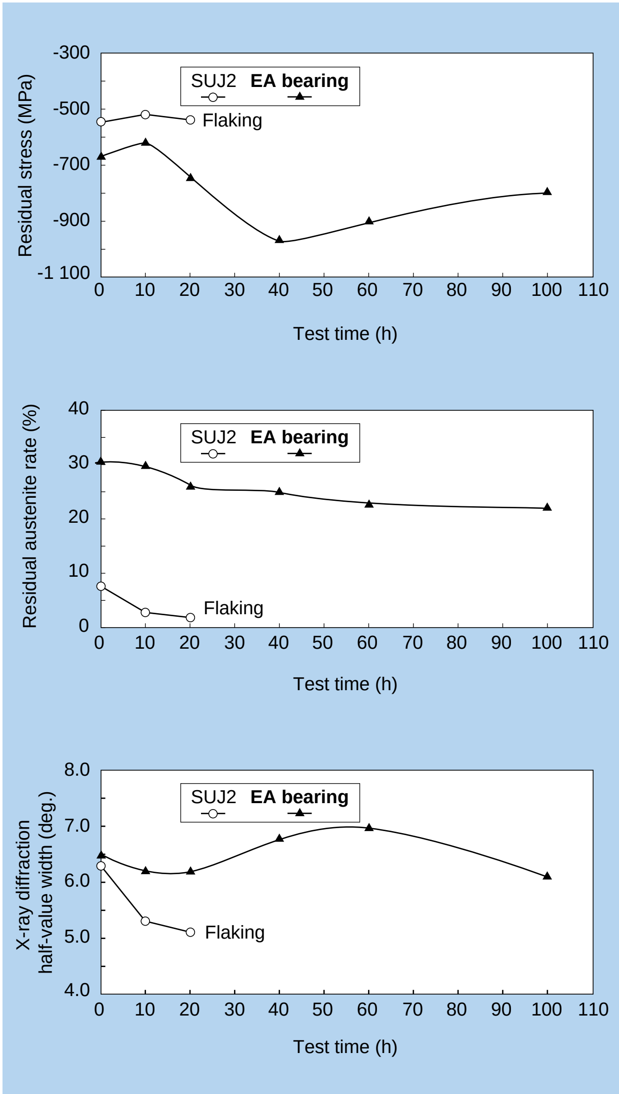


Fig.3 Material quality change on the surface when lubricant mixed with foreign material is used in the rolling fatigue test

4 Various Strength Characteristics

(1) Operating life when lubricant mixed with foreign matter is used.

Fig.4,5 show the durability results of comparison tests with small tapered roller bearings when lubricant mixed with foreign matter is used.
EA bearings display a life span of more than 5 times compared to standard carburized bearings regardless of test conditions.

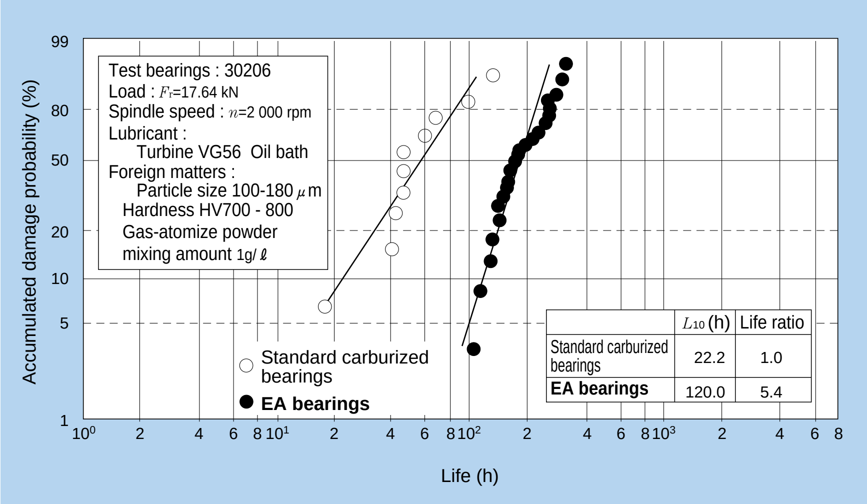

Fig.4 (Test conditions #1) Operating life results when lubricant mixed with foreign matter is used.

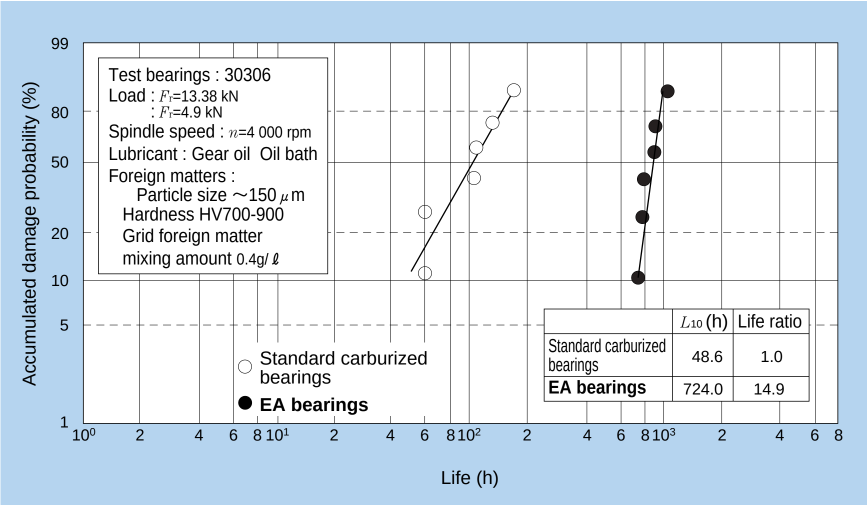

Fig.5 (Test conditions #2) Operating life results when lubricant mixed with foreign matter is used.

(2) Operating life when clean lubricant is used.

To compare the rolling fatigue strength under severe contact stress conditions, the operating life test between the standard carburized bearings and EA bearings was performed. **Fig.6** shows the result. The tests show that the EA bearings have a longer operating life than standard carburized bearings.

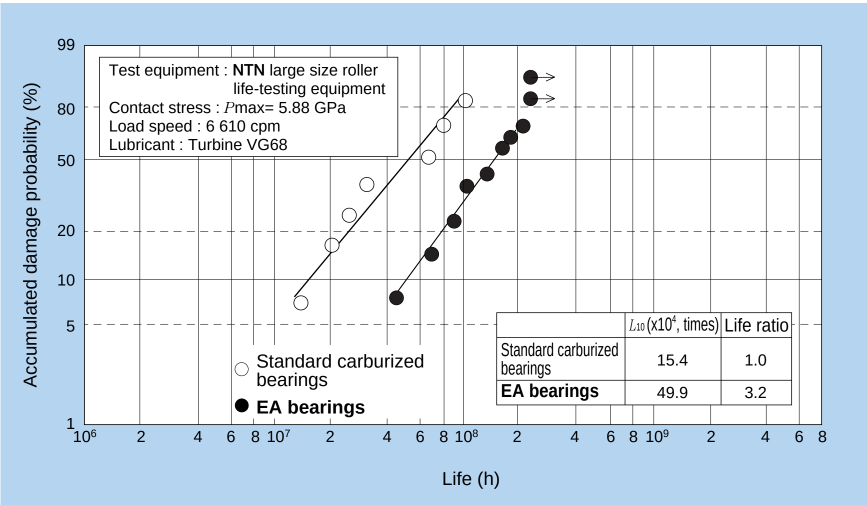

Fig.6 Operating life test results under severe stress condition with clean lubricant.

(3) Peeling Strength

Peeling damage occurs when lubrication film formation on rolling elements is insufficient and metal to metal contact takes place. It often occurs due to slippage and due to deterioration of the lubricating oil when infiltration of a sludge, water and foreign matter exists. **Fig.7** shows the strength comparison in relation to the damage. EA bearings have an incidence rate of about 1/3 compared with standard carburized bearings.

(4) Wear Resistant Strength

The sliding contact areas such as roller bearing ribs are subject to metal to metal abrasive wear in harsh lubricating conditions. The wear resistant strength has been measured using the **NTN** wear test unit. As indicated in **fig.8**, the wear trace depth of the special heat treated EA bearing has been roughly halved compared to that of the standard carburized bearings. Also as **fig.9** indicates, the EA bearing has superior fretting wear resistant characteristics.

(5) Crack Fatigue Strength

Cracking causes the destruction of the bearing. Under very severe operating conditions it is possible that this type of damage may occur. As shown in **Table 1** and **2**, EA bearings have a longer operating life than the standard carburized bearings when the results from rotation crack fatigue strength tests as well as the rolling crack fatigue strength tests with heavy press fits are compared.

Table 1 Ring test results for rotation crack fatigue strength

Bearing	L_{10}(h)×10^4 times	L_{10} ratio

NTN Bearings for Wind Turbines

風力発電装置用軸受

CAT. No. 8405-Ⅱ/JE

Wind Power – Our Energy

Solutions for the next generation of wind turbines

Wind turbine technology continues to demand increased efficiency, reliability and longer service life of equipment. Innovative bearing designs from **NTN** are instrumental in these improvements and in spreading the use of wind technology for electrical power generation. Our products are built with three concepts in mind: harmony with the natural environment, improved energy conservation and contribution to international society.

風力発電技術には、効率、信頼性、耐用年数への限りない進化が求められています。「自然環境との調和」、「エネルギー資源の保護」、「国際社会への貢献」を目指す**NTN**の軸受は、これらの要求と風力発電の普及に貢献しています。

Generator Bearings

発電機用軸受

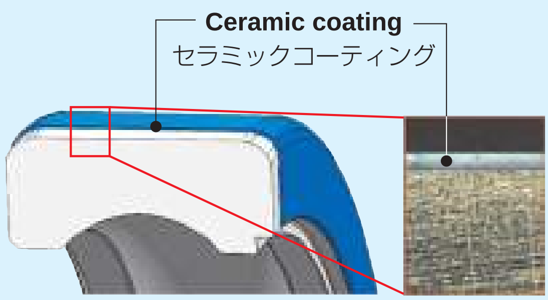
Insulated bearings for preventing the passage of electrical current through the bearings

軸受内部への通電を抑制する絶縁軸受

- A ceramic coating on the outer surface of the bearing creates an insulating layer and prevents electrical corrosion. (Insulating value when 500 V DC: 100 MΩ or more; electrical breakdown power: 3 kV or more)
- Bearing dimensions and tolerances are identical to standard product (without insulation), allowing for easy substitution.
  ※Standard products are also available upon request.

- 軸受外輪表面のセラミックコーティングにより、高い絶縁性能を実現し、電食を防止します。
  (DC500V時の絶縁性能：100MΩ以上、絶縁破壊電圧：3KV以上)
- 軸受寸法、寸法精度は標準軸受（非絶縁仕様）と同一であり、互換性を有しています。
  ※ご要望により標準軸受の製作も可能です。



Condition Monitoring System for Wind Turbines "Wind Doctor™"

風力発電装置用状態監視システム "Wind Doctor™"

RENEWABLES CERTIFICATION DNV·GL Certificate no. TC-GL-IV-1-01745-0

Wind Doctor™, an **NTN** condition monitoring system (CMS) for wind turbines, enables remote monitoring of the in-situ bearing status for early failure detection of the bearings. Utilizing diagnosis reports from **NTN** by signing the monitoring service contract, it will contribute to reduction of the maintenance cost as well as improving the availability factor of the turbines, through preventing secondary damage, advance preparation of the parts, and avoiding unexpected maintenance work.

NTNの風力発電装置用状態監視システム「Wind Doctor™」を搭載することで、軸受運転状況の遠隔監視と早期の故障検知が可能です。モニタリングサービス契約により提供される診断分析情報により、損傷の拡大防止や交換部品の事前手配、計画的な補修が行えるため、メンテナンス費用の低減だけでなく稼働率の向上にも寄与します。

Long-Life AS Series TAB/ETA Bearings

CAT. No. 3025／E

NTN Long-Life AS Series TAB/ETA Bearings

Our long-life TAB and ETA bearings are able to withstand harsh environments and load conditions.

TAB bearings

ETA bearings

Our TAB and ETA bearings were developed using new materials and a special heat treatment in order to satisfy the recent demand for longer life and more compact equipment. These bearings even last longer than the TMB (deep groove ball bearings) and ET (tapered roller bearings) bearings of our preceding long-life series. They offer excellent cost performance by enhancing equipment reliability. Don't take our word for it. See for yourself!

Applications

Ideal for applications that demand long life and compactness, such as automobile transmissions and differential pinions.

Advantages

Our TAB and ETA bearings offer better reliability, smaller size and lower cost. They also offer long life for lubrication containing hard foreign matter.

1 Features

● **Able to withstand lubrication containing hard foreign matter.**

Automobile transmission bearings are often damaged by foreign matter in the lubrication. Our TAB/ETA bearings are designed to last longer under such conditions. Our TAB bearings last five times longer than the standard type, and twice as long as our TMB Series. Our ETA bearings last nine times as long as the standard, and five times longer than our ET Series.

● **Resists peeling.**

Peeling damage is caused when lubrication conditions deteriorate during use. Our TAB/ETA bearings are designed to stretch life as long as possible by being more resistant to peeling. Our TAB bearings offer five times longer peeling life than the standard type, and our ETA bearings offer eight times longer peeling life.

2 Long-Life Mechanism

Because most bearing damage occurs on the raceway surface, **NTN** has enhanced the surface layer structure through a special heat treatment and selection of materials that have a persevering structure that does not give up surface hardness. Also, **NTN** has optimized the crowning of the tapered roller elements.

These measures inhibit formation of hairline cracks that serve as the starting point for peeling and various other types of damage, and provide merits such as long life.

2.1 Crack Resistance and Stress Relaxing Effect

Softer than martensite parent phase, *retained austenite* relaxes the stress concentration in the impression area caused by contaminated lubrication material inhibiting formation of cracks.

As shown in **Fig. 1**, residual stress shifts toward the pulling side for extreme surface layers of the impression portion in all cases, and through-hardened steel having undergone standard heat treatment produces residual tensile stress. If you compare items having special heat treatment and those having standard heat treatment, there is less harmful shift of stress to the pulling side for those having undergone special heat treatment. Special heat treatment is recognized as having a stress relaxing effect.

2.2 Reason for Long Life

For our ETA bearings, we use a moderate amount of dispersed carbides and retained austenite for the surface structure produced by the previously mentioned special heat treatment, and the structure is specially designed for thermal stability.

The raceway surface is usually affected by shear stress and heat generated by rolling, thus changing the material (residual stress, hardness, micro-structure) by tempering and fatigue, tending to produce fatigue cracks. Therefore, characteristics which prevent material from changing due to tempering (tempering resistance), and properties whereby material tends to stretch rather than crack (toughness) are effective for surface starting point type damage. Usually obtained by carbonizing, retained austenite inhibits formation and development of cracks. Because it is work-hardened (strength is enhanced), a tough material can be obtained by adding moderately, but is unstable towards heat. If combined with nitrogen under the proper conditions, penetration by nitrogen makes retained austenite and martensite parent phase (matrix) stable towards heat. Along with using material that is resistant to change, by depositing the proper amount of carbides, fatigue strength can be enhanced without losing cracking strength.

Table 1 Comparison of Impression Shape for Various Materials

Material		Surface hardness [HRC]	Retained austenite amount [%]	Impression diameter [mm]	Impression depth [μm]	Bulge amount [μm]
Through-hardened steel	Standard bearing	62.0	10	2.40	80	5
	TAB bearing	62.0	28	2.45	83	4
Carbonized steel	Standard bearing	61.0	25	2.80	102.5	1
	ETA bearing	62.5	29	2.63	97.5	1
Impression shape example		(Through-hardened steel standard bearing)

4 Life Test

Results of the life test are as given below. The data given here concerns standard and TAB/ETA bearings. Disparity however results in figures that depend on the type of foreign matter when foreign matter is mixed in with the lubrication oil. This data is provided for your reference.

4.1 Test Bearings and Test Conditions

Test bearings are given in **Table 2**, and test conditions in **Table 3** and **4**.

Table 2 Test Bearings

Bearing	Main dimensions mm	Basic dynamic load rating C_r kN	Basic static load rating C_{or}
Standard 6206	φ30×φ62×16	19.5	11.3
TAB206	↑	↑	↑
Standard 30206	φ30×φ62×17.25	43.5	48.0
ETA30206	↑	↑	↑

Table 3 Test Bearings (6206, TAB6206)

	Ordinary lubrication oil	Foreign matter mixed in with lubrication oil (reference)
Radial load kN	12.25	6.9
Number of revolutions rpm	2 000	2 000
Lubrication oil	Turbine 56	Turbine 56 + **NTN** standard foreign matter
Lubrication method	Circulating lubrication	Fueling

Table 4 Test Bearings (30206, ETA30206)

	Ordinary lubrication oil	Foreign matter mixed in with lubrication oil (reference)
Radial load kN	17.64	17.64

Bearings for Special Environments

Ultra Final Series

CAT. No. 3023-Ⅲ／E

NTN
Bearings for Special Environments

NTN responds to emerging market needs
with unique technologies for extreme environments.

C O N T E N T S

Recent advances in the process technologies employed in semiconductor fabrication and other industrial sectors have raised expectations for the bearings used in vacuum environments. Today, such bearings are required to be cleaner, more durable and more resistant to corrosion. In response, **NTN** Corporation has developed a bearing technology that employs solid lubricant for ultra-high vacuum environments.
Moreover, **NTN** has continued to expand its product line with bearings designed for corrosive environments. These innovations round out a product line that already features vacuum bearings and ultra-clean bearings designed to accommodate today's increasingly complex production environments.

1. Selecting Bearings for Extreme Environments

The operating environments of today's advanced industries — as typified by the semiconductor fabrication industry — are complex and entail a variety of factors. To simplify the selection of the optimal bearings for complex environments, please refer to **Figure 1**. It illustrates schematically three such environments — vacuum, clean and corrosive — as well as the complex interrelation among these environments. This diagram lists the typical equipment and facilities found in each environment as well as the applicable bearings.

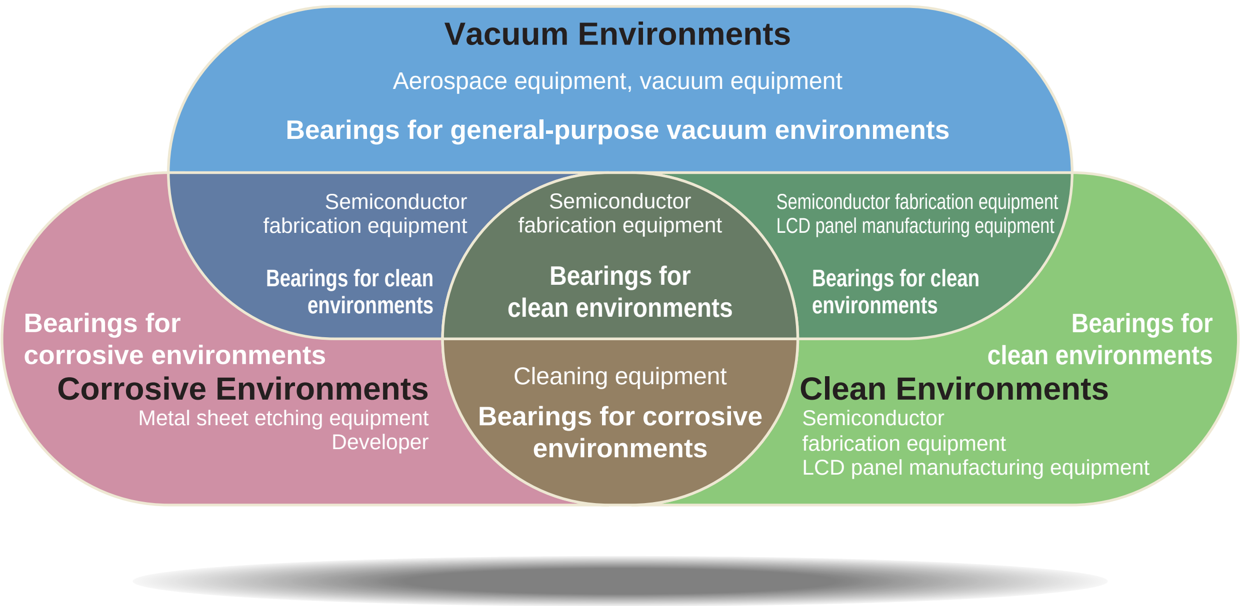

Fig. 1

2. Classifications and Standard Specifications of Bearings for Special Environments

Table 1 summarizes the standard specifications of bearings for special environments.
For custom specifications, please contact **NTN** Engineering.

Table 1. Bearings for Special Environments: Classifications and Standard Specifications

Classification	Operating Environment					Bearing Specification	
	Temperature	Atmosphere	Vacuum	Corrosives	Magnetic field	Inner Ring/Outer Ring	Ball
Vacuum environments	～150˚C	○	○			Martensite stainless steel + MoS_2 coating	Martensite stainless steel + MoS_2 coating
	～300˚C		○			Martensite stainless steel + Pb coating	Martensite stainless steel + Pb coating
	～400˚C		○			Martensite stainless steel	Martensite stainless steel + Ag coating
Clean environments	～ 70˚C	○				Martensite stainless steel	Martensite stainless steel
	～200˚C	○	○

3. Performance and Technical Data of Various Bearings

3.1 Vacuum bearings

Table 2 Performance of Vacuum Bearings

◎: Excellent ○: Good △: Fair ×: Not recommended

Bearing type	Allowable vacuum range Pa	Allowable temperature range °C	Load-carrying capacity	Low-torque performance	Out Particle	Outgassing	Electrical conductivity
MoS_2-coated bearings	10^{-5}～1	～+150	△	◎	○	○	×
Pb-coated bearings	～10^{-5}	～+300	○	◎	○	◎	○
Ag-coated bearings	～10^{-5}	～+400	△	○	○	◎	○
Bearings with vacuum grease (optional)	10^{-5}(vapor pressure) to atmospheric	～+200	◎	×	×	×	×

Note: Ratings represent relative performance among vacuum bearings.

Test Data

Results of durability evaluation.

Figures 2 through **6** provide sample evaluations of coating-dependent durability.

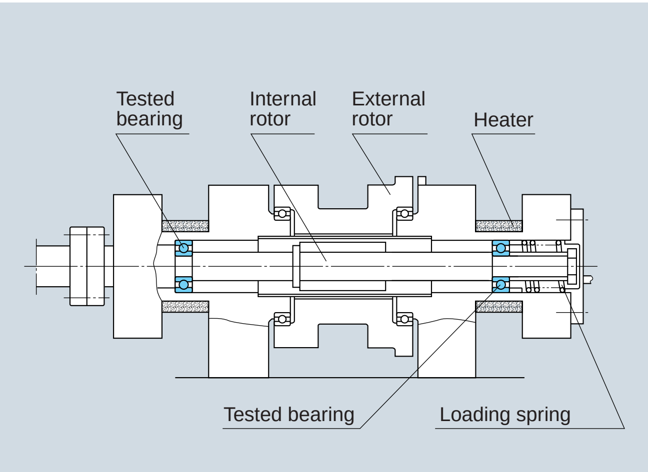

Fig. 2 Durability tester for high-vacuum bearing

● Test conditions

Bearing : Deep groove ball bearings, φ8×φ22×7 (Open type)
Axial load : 10N, 30N, 50N
Speed : 2 500min^{-1}
Degree of vacuum : Around 10^{-5} Pa
Temperature : Room temperature
Evaluation criterion : Bearing life is regarded as having expired when the bearing friction torque with two bearings reaches 10^{-2} N・m.

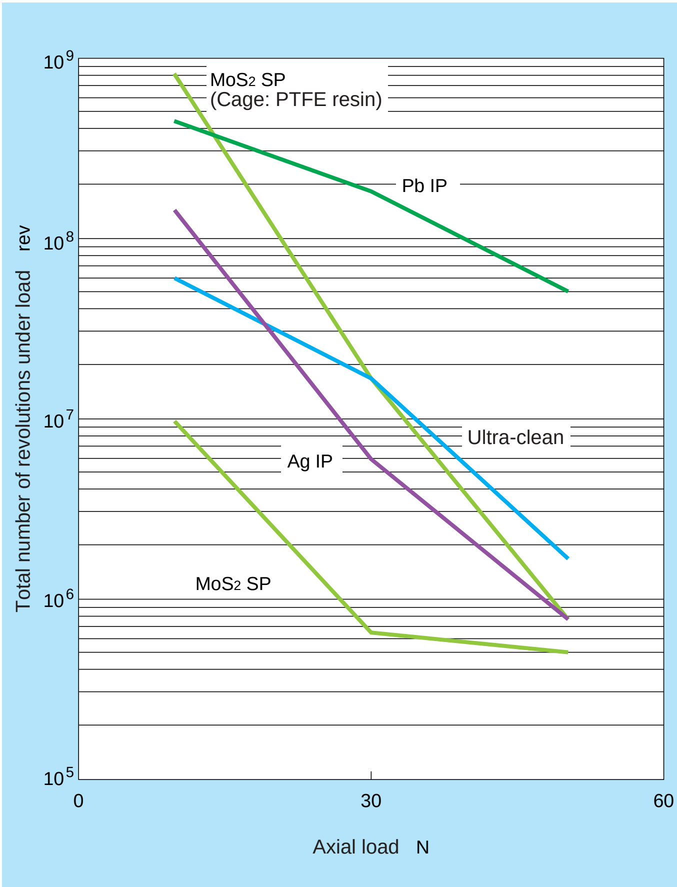

Fig. 3 Load vs. durability in a vacuum

● Test conditions

Bearing	: Angular contact ball bearings, φ10×φ22×7 (Full complement type)
Axial load	: 10N
Speed	: 2 500min^{-1}
Degree of vacuum	: Around 10^{-5} Pa
Temperature	: Room temperature

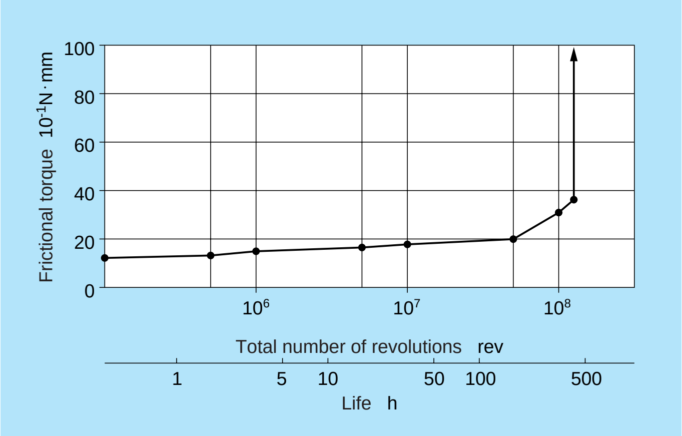

Fig. 4 Evaluation of durability of Ag IP bearing

● Test conditions

Bearing	: Angular contact ball bearings, φ10×φ22×7 (Cage: Leaded copper alloy))
Axial load	: 10N
Speed	: 7 500min^{-1}
Degree of vacuum	: Around 10^{-5} Pa
Temperature	: Room temperature

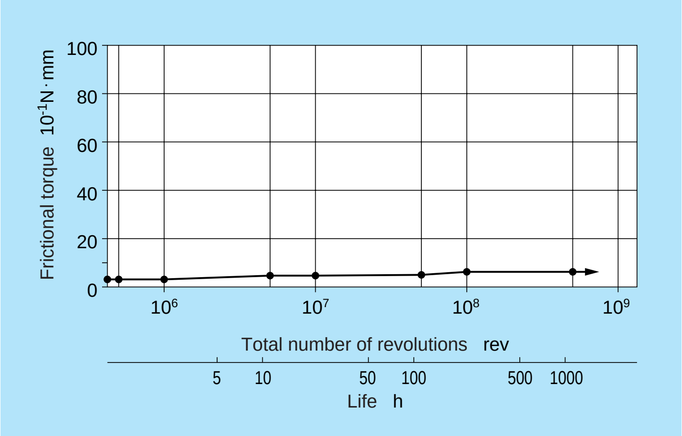

Fig. 5 Evaluation of durability of Pb IP bearing

● Test conditions

Bearing	: Angular contact ball bearings, φ10×φ22×7 (Cage: PTFE resin)
Axial load	: 10N
Speed	: 7 500min^{-1}
Degree of vacuum	: Around 10^{-5} Pa
Temperature	: Room temperature

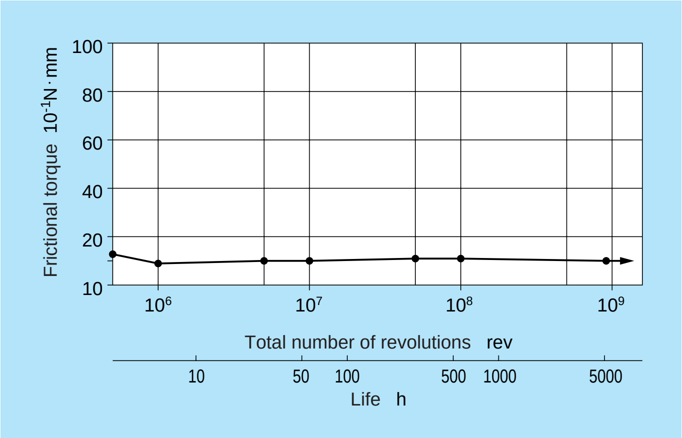

Fig. 6 Evaluation of durability of MoS_2 SP bearing

3.2 Bearings for clean environments

Table 3 Performance of Bearings for Clean Environments

◎ : Excellent ○ : Good △ : Fair × : Not recommended

Bearing type	Allowable vacuum range Pa	Allowable temperature range °C	Load-carrying capacity	Low-torque performance	Out Particle	Outgassing	Corrosion resistance	Maximum d_n value
Bearings with low out particle grease	Atmospheric	＋ 70	◎	△	△	—1)	△	20×10^4
Bearings with low out particle grease for vacuum environment	10^{-5} to atmospheric	～＋200	◎	×	△	△	△	20×10^4
Ultra-clean bearings	10^{-5} to atmospheric	～＋260	△	◎	◎	◎	△	1×10^4
Long life ultra-clean bearings	10^{-6} to atmospheric	～＋300	△	◎	○	◎	△	1×10^4

Note: Ratings represent relative performance among bearings designed for clean environments.
1) Excluded from evaluation because this type of bearing is used under atmospheric pressure.

Test Data

3.2.1 Evaluation of out particle characteristics

Figures 7 through **13** provide evaluations of the tendency to out particles.

● Test conditions

Bearing : Deep groove ball bearings φ8×φ22×7
Axial load : 10N
Speed : $50min^{-1}$
Minimum particle size measured : 0.3 µm
Temperature : Room temperature

● Test results

· Generation of airborne particles is indicated as the number of particles present in one cubic foot of collected air (number of particles/cf).
· **NTN**'s ultra-clean bearings generate a very low particle count (equivalent to Class 10).

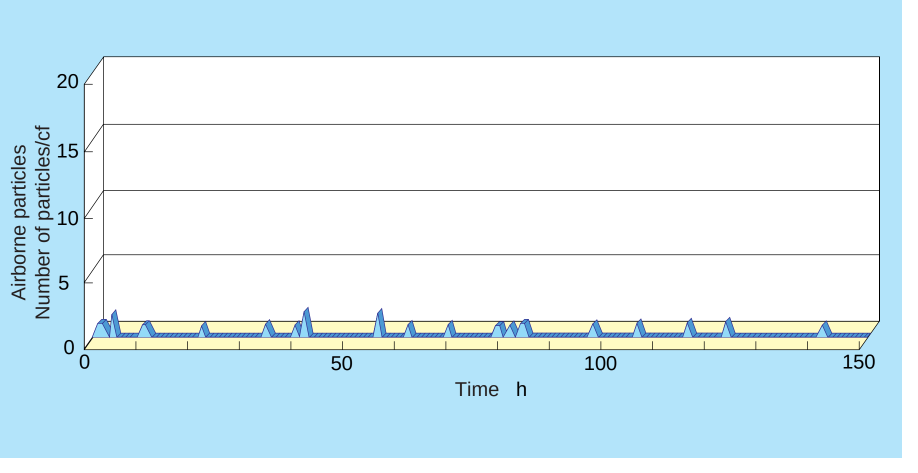

Fig. 7 Measurement of out particle by ultra-clean bearing (at atmospheric pressure)

● Test conditions

Bearing : Deep groove ball bearings φ8×φ22×7
Axial load : 10N (50N)
Speed : $50min^{-1}$
Degree of vacuum : Around 10^{-5} Pa
Minimum particle size measured : 0.38 µm
Temperature : Room temperature (20°C)

● Test results

· The out particle characteristics of ultra-clean bearings are not significantly altered by load or temperature. This type of bearing exhibits low out particle over a wider range of conditions.

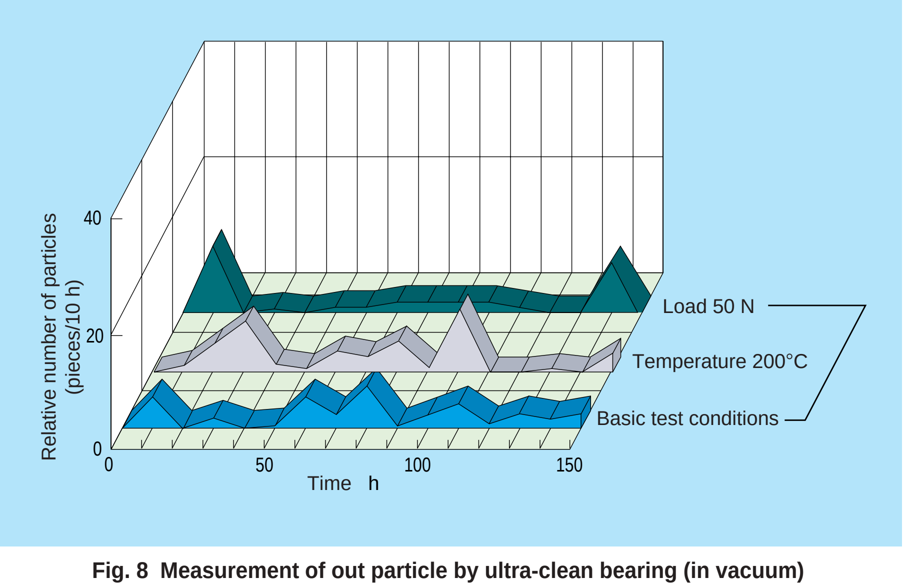

Fig. 8 Measurement of out particle by ultra-clean bearing (in vacuum)

● Test conditions

Bearing : Deep groove ball bearings φ8×φ22×7
Axial load : 10N
Speed : 50min^{-1}
Minimum particle size measured : 0.38 μm
Degree of vacuum : Around 10^{-5} Pa

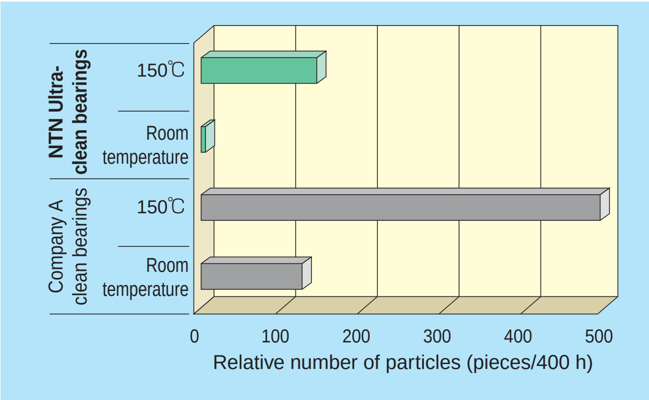

Fig. 9 Measurement of out particle by ultra-clean bearing (in vacuum)

● Test conditions

Bearing : Deep groove ball bearings φ8×φ22×7
Axial load : 10N
Minimum particle size measured : 0.1 μm
Temperature : Room temperature

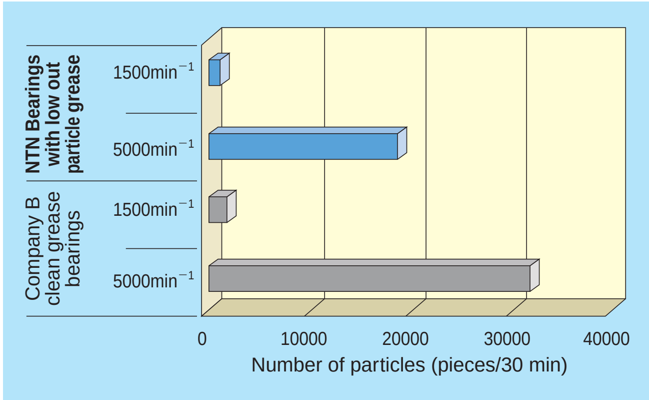

Fig. 10 Measurement of out particles by bearing with low out particle grease (at atmospheric pressure)

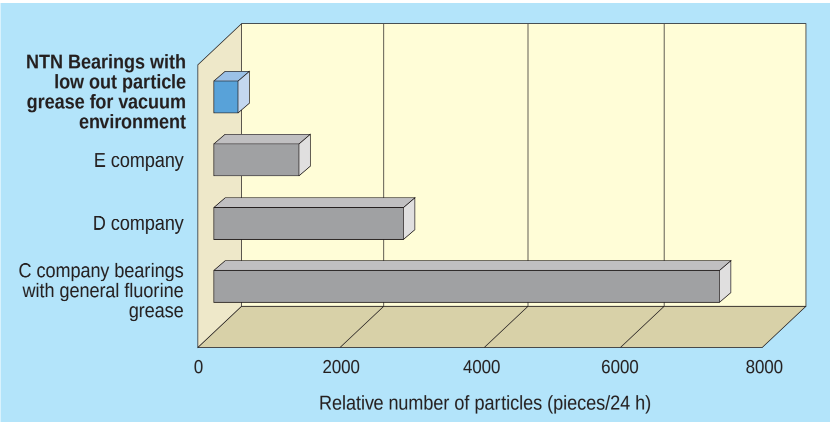

Fig. 11 Measurement of out particles by bearing prelubricated with low out particle vacuum grease (in vacuum)

● Test conditions

Bearing : Deep groove ball bearings φ8×φ22×7
Axial load : 30N
Speed : 200min^{-1}
Minimum particle size measured : 0.2 μm
Degree of vacuum : Around 10^{-5} Pa

● Test conditions

Bearing : Deep groove ball bearings φ10×φ26×8
Axial load : 15N
Minimum particle size generated : 0.1 μm
Temperature : Room temperature (at atmospheric pressure)

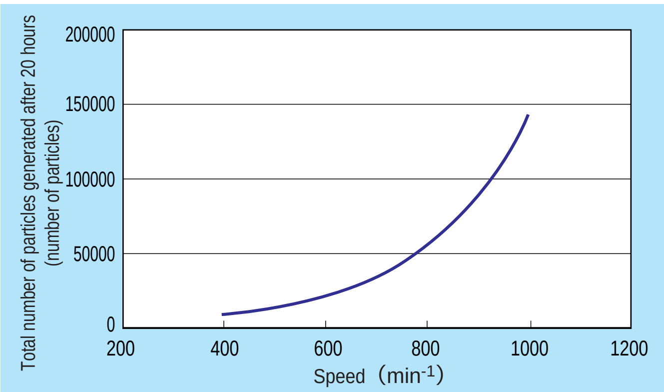

Fig. 12 Relation between bearing speed and number of out particles (bearing with low out particle grease)

● Test conditions

Bearing : Deep groove ball bearings φ10×φ26×8
Speed : 400min^{-1}
Minimum particle size generated : 0.1 μm
Temperature : Room temperature (at atmospheric pressure)

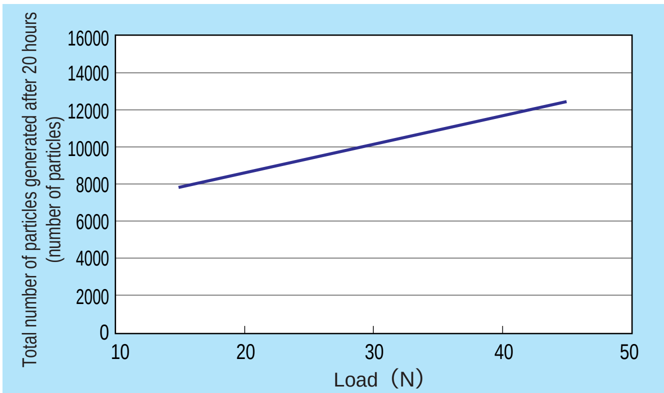

Fig. 13 Relation between axial load and number of out particles (bearing with low out particle grease)

3.2.2 Results of durability evaluation

Figures 14 through **16** provide evaluations of bearing durability.

● Test conditions

Bearing : Deep groove ball bearings φ8×φ22×7
Axial load : 10N
Speed : 360min^{-1}
Degree of vacuum : Around 10^{-5} Pa
Temperature : Room temperature

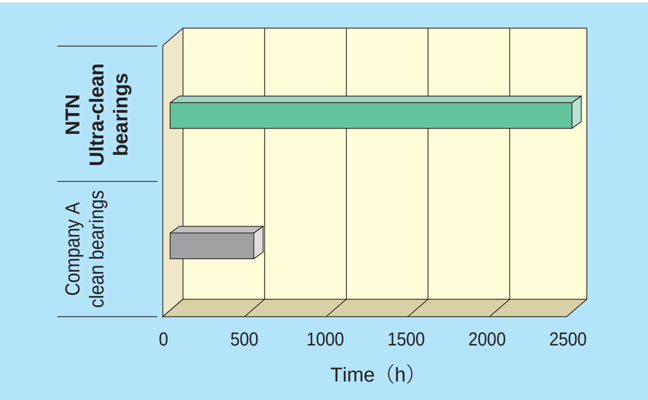

Fig. 14 Evaluation of durability of ultra-clean bearing

● Test conditions

Bearing : Deep groove ball bearings φ20×φ47×14
Axial load : 67N
Radial load : 67N
Speed : 10000min^{-1}
Temperature : 100˚C

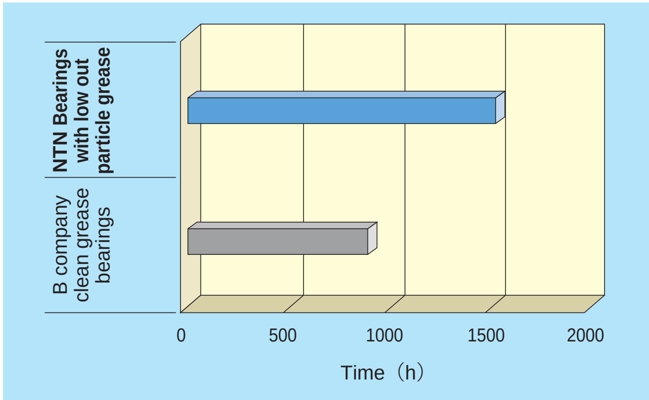

Fig. 16 Evaluation of durability of bearing with low out particle grease

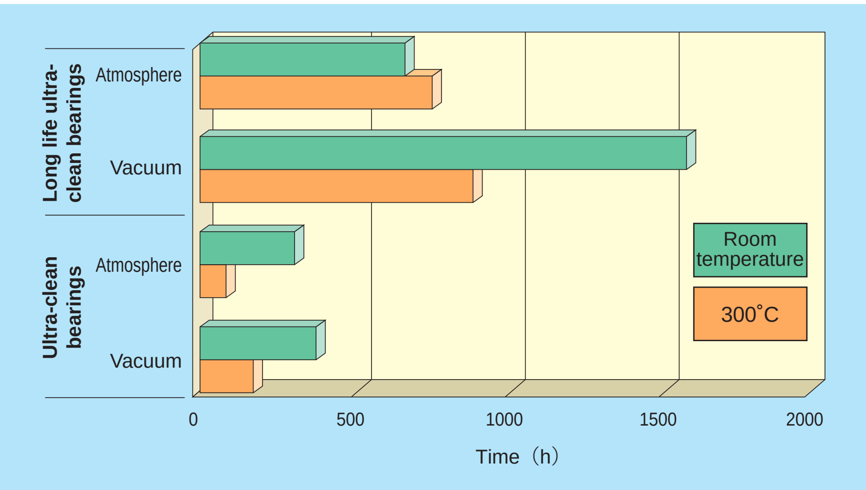

Fig. 15 Evaluation of durability of long-life ultra-clean bearing

● Test conditions

Bearing : Deep groove ball bearings φ8×φ22×7
Axial load : 10N
Speed : 2500min^{-1}
Atmospheric pressure/vacuum (around 10^{-5} Pa)

3.2.3 Evaluations of outgassing characteristics

Figures 17 and **18** provide evaluations of outgassing characteristics.

● Test conditions

Bearing : Ultra-clean bearing 6 mm dia.×19 mm dia.×6
: Bearing with vacuum grease 6 mm dia.×19 mm dia.×6
: Untreated bearing (PTFE cage) 9.5 mm dia.×22 mm dia.×7.1

Degree of vacuum : Around 10^{-5} Pa

Temperature : Room temperature, 200˚C

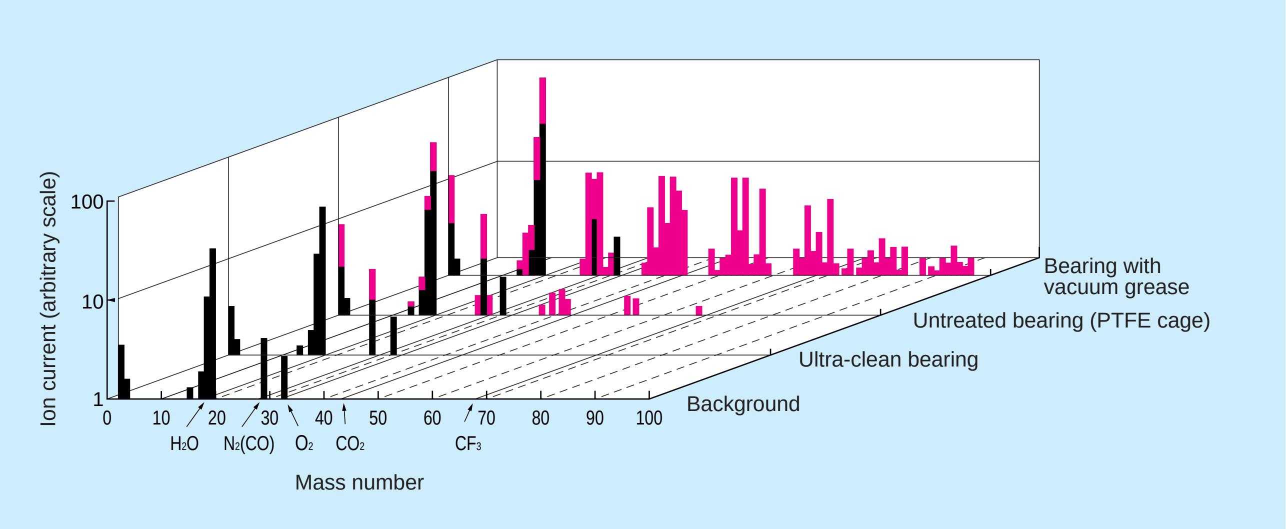

Fig. 17 Example of gasses released immediately after installation of bearing (at room temperature)

- Components that increased after bearing installation are indicated in red, relative to the background measurement of the test equipment.
- The diagram shows that H_2O, N_2 (CO), O_2 and the like are present as background components.
- The ultra-clean bearing exhibited some increase in N_2 (CO) outgassing, but did not show increased outgassing of other components. Additionally, while running, it did not exhibit any increase in outgassing. The **NTN** ultra-clean bearing always exhibits low outgassing.

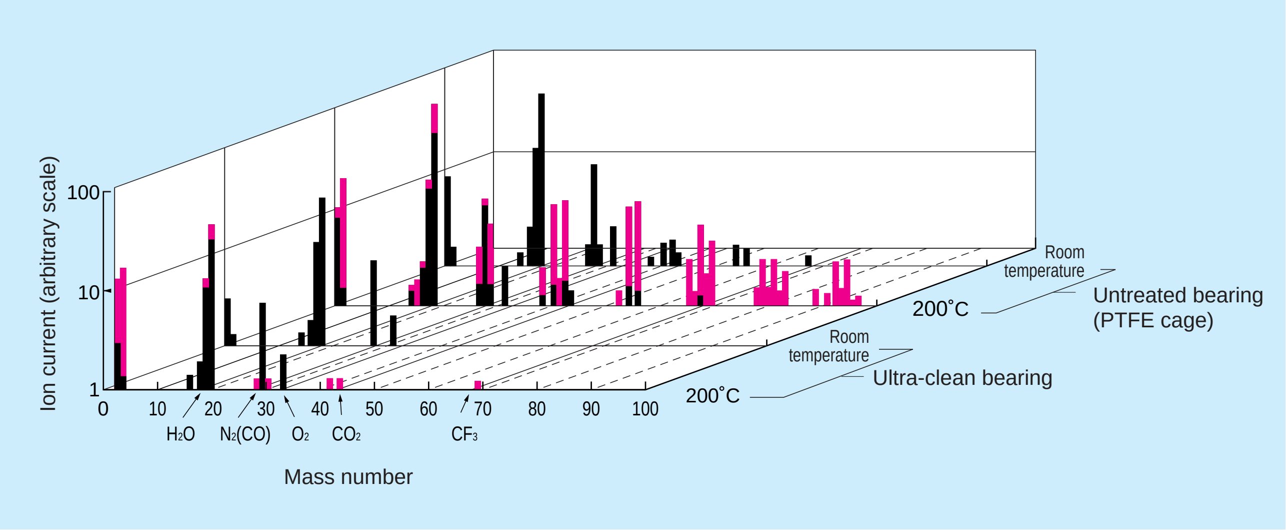

Fig. 18 Comparison of outgassing at room temperature and high temperature

- Components that increased as a result of the temperature increase from room temperature to 200˚C are indicated in red.
- At 200˚C, the amount of gasses released by the ultra-clean bearing somewhat exceed the amount released at room temperature. However, the amount remained small, indicating the low outgassing characteristic of the ultra-clean bearing even in high-temperature applications.

3.3 Bearings for corrosive environments

Table 4 Performance of Bearings for Corrosive Environments

	Applicable temperature range ˚C	Load-carrying capability
PPS resin rolling bearing	Room temperature to 150˚C	Yes

Table 5 Corrosion resistance of bearings for corrosive environments

○ : Good △ : Fair × : Not recommended

	Inner ring & outer ring	Cage			Rolling elements	
	PPS resin	Polyimide resin (optional)	Polyamide resin (optional)	PTFE resin	Ceramic	Glass
10% hydrochloric acid	○	○	×	○	○	△
35% sulfuric acid	○	○	×	○	○	○
35% nitric acid	○	○	×	○	○	○
10% acetic acid	○	△	×	○	○	○
10% potassium hydroxide	○	△	○	○	○	×
10% sodium hydroxide	○	△	○	○	○	×
30% aqueous ammonia	○	△	×	○	○	○

3.4 Electrically conductive bearings

● Test conditions

Bearing : Deep groove ball bearings φ30×φ42×7
Speed : $150min^{-1}$
Speed : 50N
Temperature : Room temperature

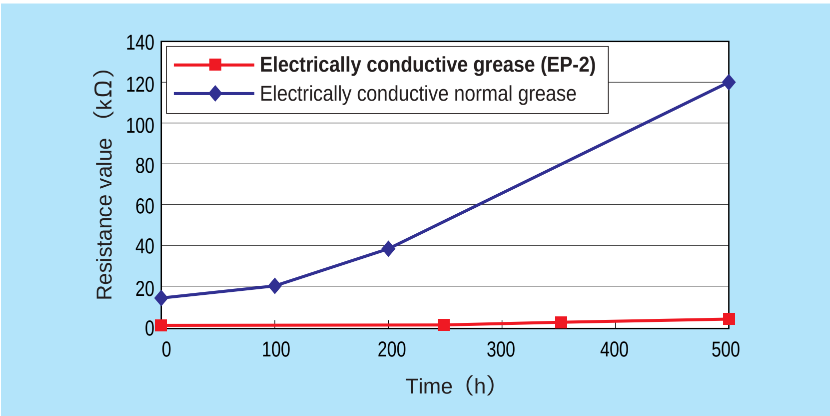

Fig. 19 Durability with electrically conductive grease (EP-2)

4. Material Characteristics

Table 6 Comparison of Characteristics of Ceramic (Si_3N_4) and Bearing Steel (SUJ2)

Characteristics		Ceramic (Si_3N_4)	Bearing Steel (SUJ2)
Hardness	HV	1500	750
Density	g/cm^3	3.2	7.8
Young's modulus	GPa	310	210
Poisson's ratio		0.26	0.3
Coefficient of thermal expansion	$\times 10^{-6}/˚C$	3.0	12.5
Thermal conductivity	W/m·k	29	46
Magnetism		Non-magnetic	Ferromagnetic
Corrosion resistance		Good	Poor
Electrical conductivity		Insulator	Conductor

5. Applications

Table 7 summarizes typical applications of **NTN** bearings designed for extreme environments.

Table 7 Typical Applications of Bearings for Extreme Environments

Equipment	Machine/Device	Application	For Vacuum Environments				For Clean Environments				For Corrosive Environments
			Vacuum grease	Ag coating	Pb coating	MoS_2 coating	Ultra-clean	Long-life ultra-clean	Low out particle grease	Low out particle vacuum grease	PPS resin

1) Minimum allowable chamfer dimension r.
2) Seal grooves may be provided in some cases.
3) Allowable radial load is the maximum allowable load with only a radial load applied.
4) Maximum allowable temperature is 120˚C (260˚C for others).
5) The basic dynamic load rating is the value for stainless steel bearings.

The lead time for products in this table is two weeks.

Note: **NTN** continue to expand our product line. For information on bearings not included in this table, contact **NTN** Engineering.

1) Minimum allowable chamfer dimension.
2) Maximum allowable temperature is 120˚C (200˚C for others).
3) The basic dynamic load rating is the value for stainless steel bearings.

The lead time for products in this table is two weeks.

Note: **NTN** continue to expand our product line. For information on bearings not included in this table, contact **NTN** Engineering.

Handling Precautions

(1) Bearing components have been thoroughly degreased. Do not touch any bearing component with bare hands. Doing so may cause rusting of the bearing. Always wear clean, lint-free gloves when installing a bearing.
(2) Do not rinse a bearing with an organic solvent. Doing so may lead to lubricant leakage or damage to the lubricant film.
(3) Do not unpack a vacuum-packed or heat-packed bearing until immediately before installation. Otherwise, the bearing may rust or become contaminated with dust. If the bearing will not be used for an extended period, store it in a dry, closed container such as a desiccator.

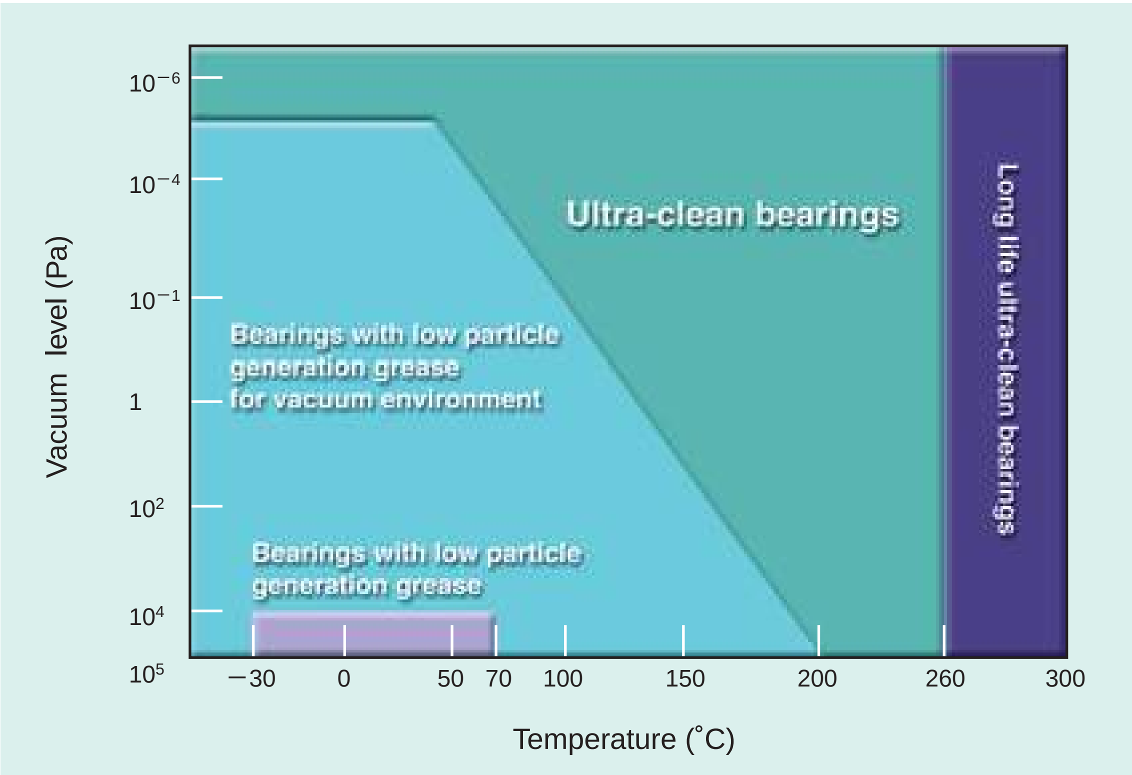
NTN bearings for clean environments

CONTENTS

NTN bearings for clean environments

Ultra Final Series bearings for clean environments are bearings that produce minimal dust for vacuum equipment, transfer equipment, and equipment for manufacturing semiconductors, liquid crystal and electronic components.

Range of NTN bearings for clean environment



1. Standard specifications of bearings for clean environments

The standard specifications of bearings for clean environments are as follows.
For more details, contact **NTN** Engineering.

Classification of bearings	Appearance	Lubricant	Configuration
Ultra-clean bearings		Special PTFE	 Raceway groove and rolling elements
Long life Ultra-clean bearings		Special PTFE + Special ball	 Raceway groove and rolling elements
Bearings with low particle generation grease		**NTN** low particle generation grease	Bearings with low particle generation grease for vacuum environment		Fluorine grease

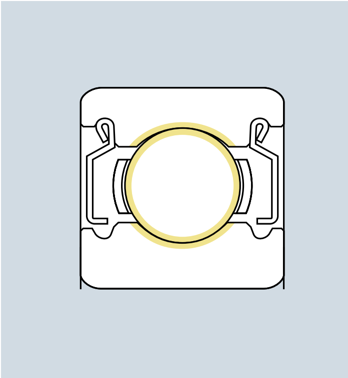
2. Ultra-clean bearings (vacuum / high temperature)

● Appearance and configuration

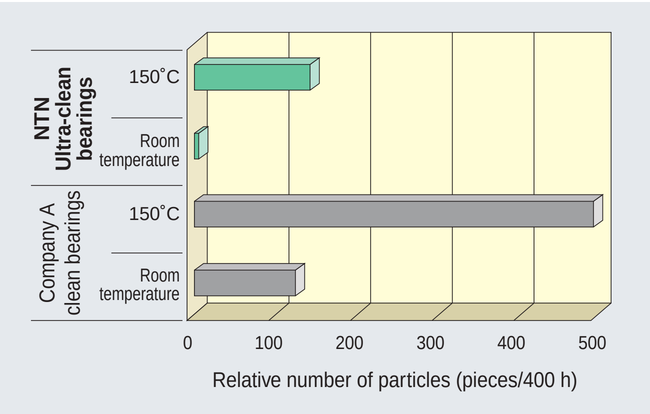


● Standard specifications

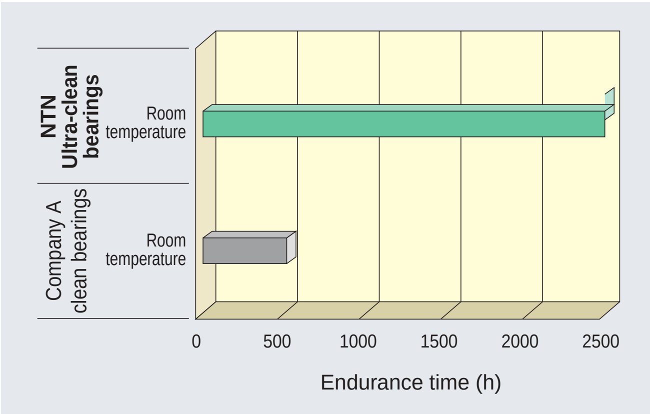
Inner and outer rings	: Martensite stainless steel
Rolling elements	: Martensite stainless steel
Cage	: Austenite stainless steel
Lubricant	: Special PTFE
Shield	: Austenite stainless steel

● Characteristics of particle generation and durability

1) Part No. : 608
2) Axial load : 10N
3) Rotational speed : 50min^{-1}
4) Vacuum level : 10^{-5}Pa



1) Part No. : 608
2) Axial load : 10N
3) Rotational speed : 360min^{-1}
4) Vacuum level : 10^{-5}Pa



● Features

1. Low particle generation, corrosion resistance.
2. Low torque.
3. Can be used in high temperature and high vacuum conditions.
4. Long life.

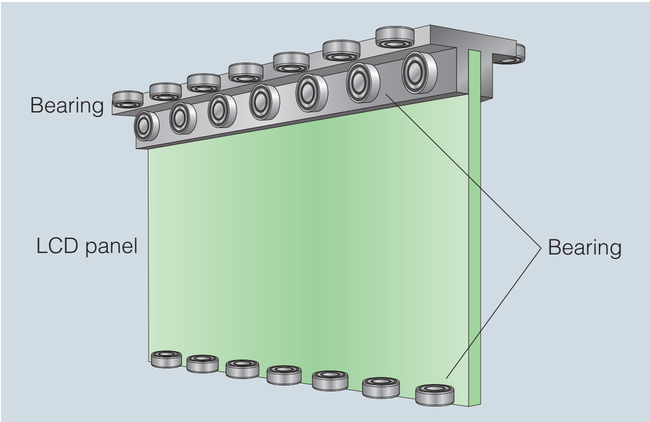
● Ex.) part No.

MT2－SEB08J1ZZ1C3／0G

● Operating temperature

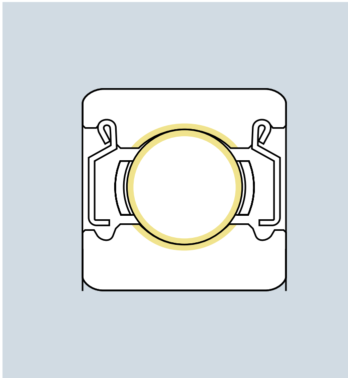
～ 260˚C

● Application example: Transfer equipment of LCD panel



3. Long life ultra-clean bearings (vacuum / high temperature)

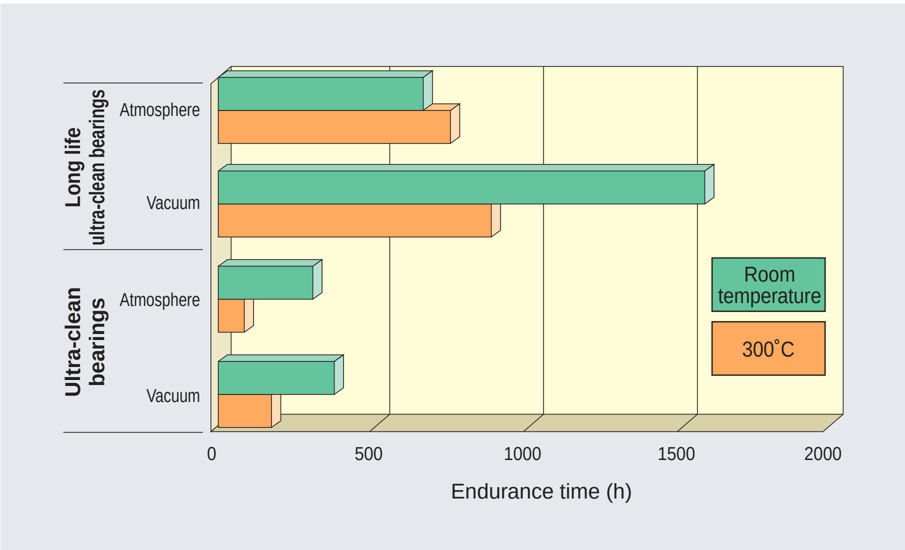
● Appearance and configuration



● Standard specifications

Inner and outer rings	: Martensite stainless steel
Rolling elements	: Martensite stainless steel
Cage	: Austenite stainless steel
Lubricant	: Special PTFE and special ball
Shield	: Austenite stainless steel

● Durability



1) Part No. : 608
2) Axial load : 10N
3) Rotational speed : 2500min^{-1}
4) Atmosphere/vacuum (10^{-4}Pa)

● Features

1. Low particle generation, corrosion resistance.
2. Low torque.
3. Longer life than ultra-clean bearing.

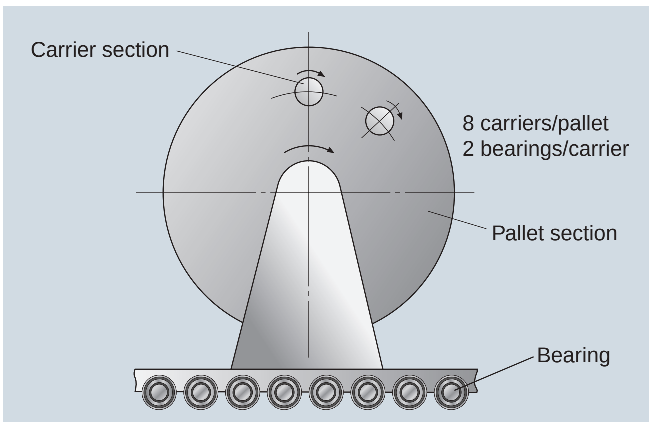
● Ex.) part No.

MT2－5PT－SEB08J1ZZ1C3／0G

● Operating temperature

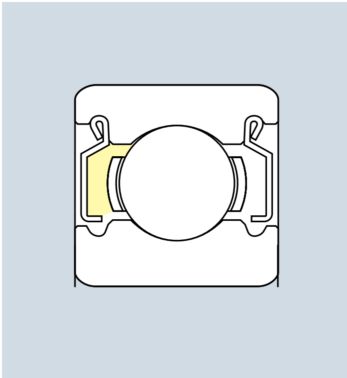
～300˚C

● Application example: Transfer equipment of HD substrate



4. Bearings with low particle generation grease (atmosphere / room temperature)

● Appearance and configuration

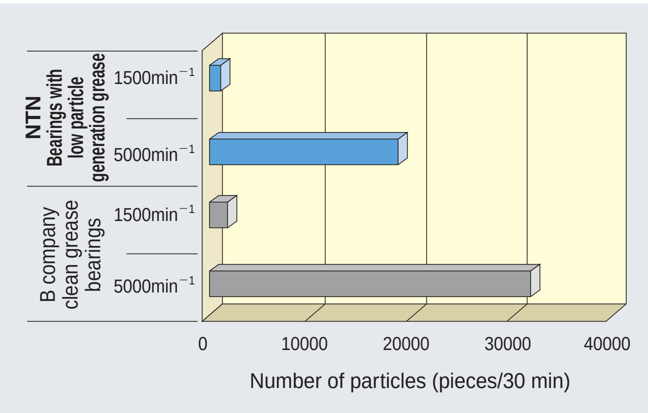


● Standard specifications

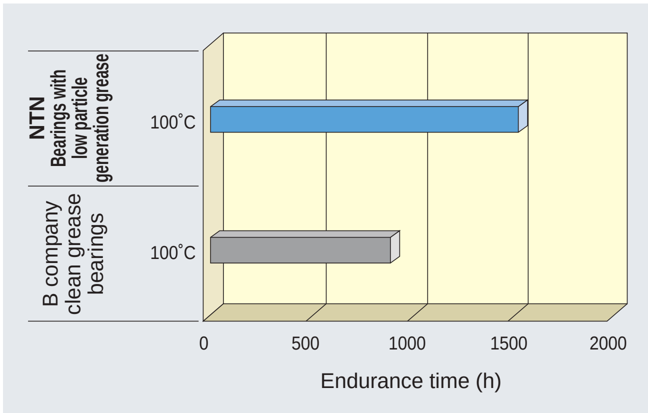
Inner and outer rings	: Martensite stainless steel
Rolling elements	: Martensite stainless steel
Cage	: Austenite stainless steel
Lubricant	: **NTN** low dusting grease ZD-1 (L635)
Shield	: Austenite stainless steel

● Characteristics of particle generation and durability

1）Part No. : 608
2）Axial load : 10N
3）Temperature : Room temperature



1）Part No. : 6204
2）Axial load : 67N
3）Rotational speed : 10000min^{-1}



● Features

1. Low particle generation, corrosion resistance.
2. Low torque.
3. Long life.

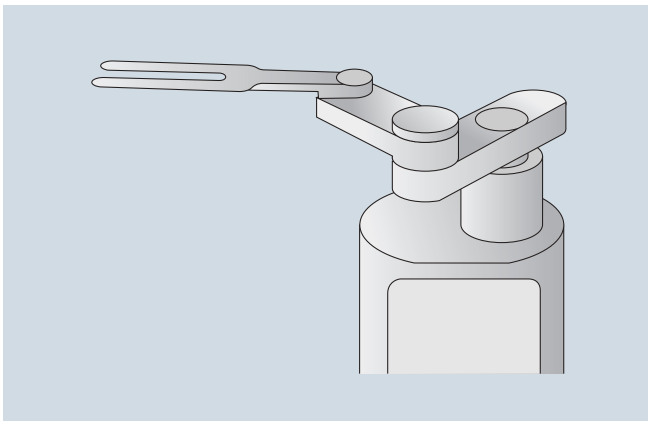
● Ex.) part No.

SEB08J1ZZ1C3／L635QMP

● Operating temperature

～70˚C

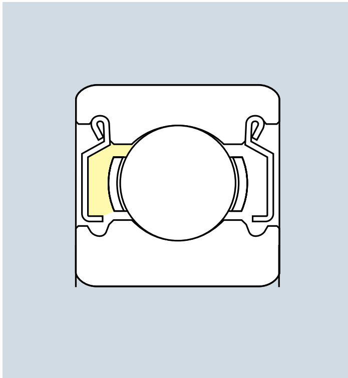
● Application example: Transfer robot



Cam follower and bearing unit with low particle generation grease are available.

5. Bearings with low particle generation grease for vacuum environment (vacuum / high temperature)

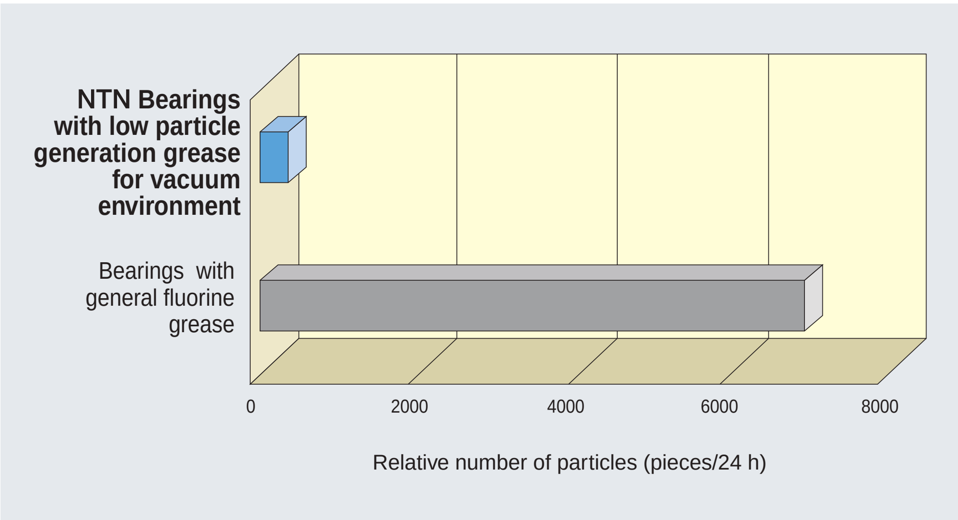
● Appearance and configuration



● Standard specifications

Inner and outer rings	: Martensite stainless steel
Rolling elements	: Martensite stainless steel
Cage	: Austenite stainless steel
Lubricant	: Low particle generation grease for vacuum environment (LX23)
Shield	: Austenite stainless steel

● Dusting characteristics of particle generation



1) Part No. : 608
2) Axial load : 29.4N
3) Rotational speed : 200min^{-1}
4) Vacuum level : 10^{-5}Pa

● Features

1. Low particle generation, corrosion resistance.
2. Can be used in high temperature and high vacuum conditions.
3. Long life.

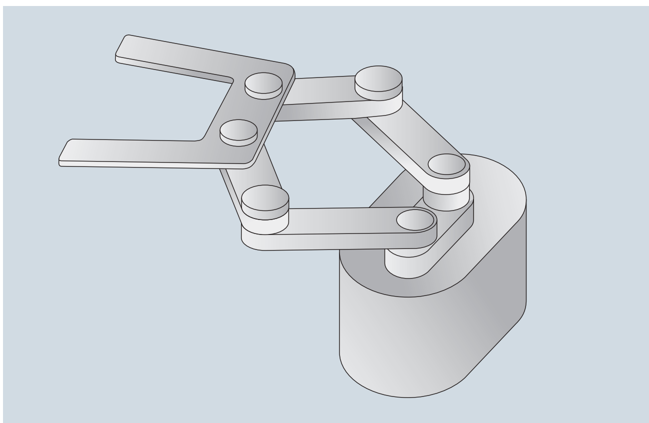
● Ex.) part No.

SEB08J1ZZ1C3／LX23Q109

● Operating temperature

～200˚C

● Application example: LCD transfer robot



Cam follower and bearing unit with low particle generation grease for vacuum environment are available.

1) Minimum allowable chamfer dimension.
2)Allowable temperature for this bearing is 120˚C. For others, 200˚C.

7. Introduction bearings for special environments

7. 1 Cam followers

CAT. NO. 3604

Features

- **NTN** offers a rich assortment of stainless steel cam followers that use low dusting grease or solid grease to maintain a clean environment.

7. 3 Ball screws

CAT. NO. 6002

Features

- All parts are made of stainless steel except the dust seal.
- Ball screws are vacuum grease sealed or provided with RAYDENT depending on working environment and conditions.
- Low dusting; can be used in both atmosphere and vacuums.

7. 5 Plastic rolling bearings

CAT. NO. 3023

Features

- Equipped with self-lubricating, corrosion-resistant plastic raceways and glass or ceramic balls.
- Doesn't require lubrication; offers lower torque than sliding bearings.
- Low dusting.

7. 2 Bearing units /Stainless steel series

CAT. NO. 3903/E

Features

- Housing and inner/outer rings are made of stainless steel. Maintain a clean environment by using low particle generation grease or bearings with solid grease.

7. 4 Miniature sliding screws with plastic nut

CAT. NO. 5112/E

Features

- Combination of nuts made of BEAREE AS5000 and screws made of stainless steel (SUS304) provides resistance to various environments, like corrosion and high temperature etc.
- Less noise than stainless steel ball screws.

NTN®

Bearings with solid grease

Patent pending

CAT. NO. 3022-Ⅷ/E

NTN
BEARINGS with SOLID GREASE

Bearings with general-purpose solid grease

Bearings with food-grade solid grease

Overview

"Solid grease" is a lubricant essentially composed of lubricating grease and ultra-high polymer polyethylene. Solid grease has the same viscosity as ordinary grease at normal temperature, but as a result of a special heat treatment process, this grease solidifies retaining a large proportion of the lubricant in it. Thanks to this solidification, the grease does not easily leak from the bearing, even when the bearing is subjected to strong vibrations or centrifugal force, helping to extend bearing life.

Bearings with solid grease are available in two types: the spot-pack type in which solid grease is injected into the retainer, and the full-pack type in which all empty space around the rolling elements is filled with solid grease.
Spot-pack solid grease is standard for deep groove ball bearings, small diameter ball bearings, and bearing units. Full-pack solid grease is standard for self-aligning ball bearings, self-aligning roller bearings, and needle roller bearings.

Table 1 Major components in solid greases

Solid grease (code)	Resin	Lubricant
General-purpose solid grease (LP03)	Ultra-high polymer polyethylene ❶	Li-mineral oil grease
Food-grade solid grease (LP09)	Ultra-high polymer polyethylene ❶	Urea-synthetic oil grease ❷

❶ Conforms to FDA standard.
❷ Conforms to H-1 standard of NSF.

●Solid grease filling options

Deep groove ball bearings (spot-pack)

Bearing units (spot-pack)

Spherical roller bearings (full-pack)

Needle roller bearings (full-pack)

Features

1. Reduced lubricant leakage

Because the base oil is retained in a solid mixture, it is less likely to leak out of the bearing. During operation, temperature rise and/or centrifugal force will cause a gradual release of the base oil into the raceway groove. Eliminating grease leakage from the bearing ensures a consistent supply of lubricant and prevents contamination of the surrounding environment.

2. Superior lubrication

Bearings with solid grease resist grease leakage prolonging bearing life in applications where high centrifugal force or vibration are present. The solid lubricant does not emulsify when exposed to water also extending both grease and bearing life.

3. Low torque characteristics

The running torque of spot-pack bearings with solid grease is lower than that of bearings using standard lubricants. With conventional greases, a shearing resistance is created as the grease is channeled out of the raceway groove. Spot-pack bearings with solid grease do not experience shear resistance resulting in a lower running torque.

4. Sealing effect

Though solid grease protects a bearing against ingress of foreign matters (water, dust, etc.), it is not a sufficient means as a sealing device. Therefore, for applications that need reliable sealing performance, we recommend the use of contact type rubber seals (deep groove ball bearings, bearing units) or other seals (other bearing types).

1 Availability

1. Bearings with general-purpose solid grease (LP03)

Table 2 (○:standard △:special ×:not available)

Bearing	Type		Bearing size Bearing out. dia.
	Spot-pack	Full-pack	
Deep groove ball bearings	○❶	△	Up to 350 mm dia.
Miniature bearings Small dia. ball bearings	○❶	×	Inside diameter from 6 to 9 mm
Self-aligning ball bearings	×	○❶	Up to 250 mm dia.
Spherical roller bearings	×	○❶	Up to 250 mm dia.
Bearing units	○❶	△	Up to 300 mm dia.
Needle roller bearings	×	○❷	Note ❷

❶ Deep groove ball bearings with spot-pack configuration and ZZ shields are standard. Certain types and sizes of standard bearings listed in the table above are not available with solid grease. For further information, consult **NTN** Engineering by specifying the intended bearing type and size.
❷ Available bearing size for needle roller bearings varies depending on bearing type. For further information, contact **NTN** Engineering.
Note: The bearing components are not composed of a corrosion-proof material.

2. Spot-pack configuration for bearings with food-grade solid grease (LP09)

F-UC204D1 to F-UC210D1
(Bearing units-stainless steel series)
Stainless steel deep groove ball bearings ❶ (bearing outside diameter 250 mm or less)

2 Allowable Temperature Range

The maximum operating temperature on the outer ring of bearings with solid grease must fall within the ranges in **Table 3** below.
The bearings with solid grease may be assembled by "shrink fit" technique. However, be absolutely sure that that the maximum heating temperature does not exceed 100˚C, the heating time is shorter than 2 hours, and the bearing does not turn during the shrink fit process.

Table 3

	Bearings with general-purpose solid grease (LP03)	Bearings with food-grade solid grease (LP09)
Allowable temperature range	-20˚C~80˚C (Long-time operation: 60˚C or less)	-10˚C~100˚C (Long-time operation: 80˚C or less)

3 Allowable Speed

Table 4 Allowable speed for bearings with solid grease

Bearing type	Load type	Allowable speed (d_n value) ❶		
		general-purpose		food-grade
		Spot-pack	Full-pack	Spot-pack
Deep groove ball bearings	Radial load	20×10^4	5×10^4	10×10^4 ❸
Miniature bearings Small dia. ball bearings	Radial load	20×10^4	—	—
Self-aligning ball bearings	Radial load	—	3×10^4	—
Spherical roller bearings	Radial load	—	3×10^4	—
	Axial load/radial load≦0.3	—	2×10^4	—
Bearing units	Radial load	12×10^4	3×10^4	10×10^4
Needle roller bearings	Radial load	—	3×10^4 ❷	—

❶ d_n value: (d = bearing bore dia. [mm])×(n = service speed [min^{-1}])
❷ $F_w.n$ value: (F_w = roller set bore dia. [mm])×(n = service speed [min^{-1}])
❸ If intending a speed exceeding an allowable speed, consult **NTN** Engineering.

4 Minimum Required Load

A minimum radial load is required to prevent skidding of the rolling elements when using full-pack solid grease. The minimum load required is approximately 1% of the bearing dynamic load rating.
Please consult **NTN** for further details.

5
Performance test data

(1) Lubricant Leakage Test

Non shielded/sealed test bearings (spot-pack) were subjected to a centrifugal acceleration of 3,000 G (5,000 min^{-1}) for a period of four hours. Lubricant leakage from the **NTN** bearings with solid grease was approximately 2.0% by weight for the horizontally mounted condition, and approximately 5.0% by weight for the vertically mounted condition.
(Standard grease filled bearings using contact (LU) and non-contact (LB) seals were also subjected to the above test. Within ten minutes after starting the test, centrifugal force caused the seals to become displaced allowing the grease to expel.)

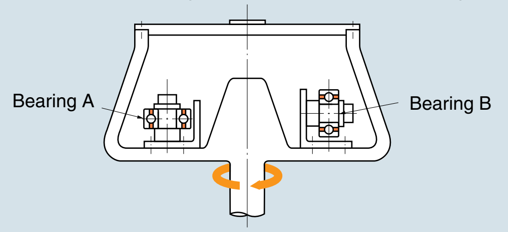

Fig. 1 Lubricant leakage test method

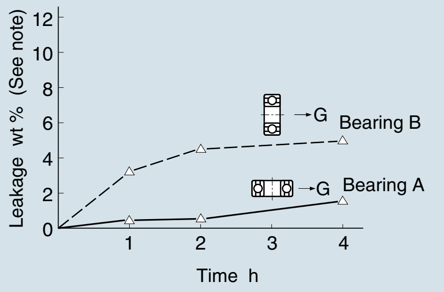

Fig. 2 Lubricant leakage test results

Note) Leakage: weight ratio of leaked lubricant compared to the amount (100%) of **NTN** Solid grease filled

Table 5 Lubricant leakage test conditions

	Bearing A	Bearing B
Test pieces	6201(Solid grease, spot-pack, open) 6201LLU(lithium mineral oil grease, contact type rubber seal) 6201LLB(lithium mineral oil grease, non-contact type rubber seal)	
Centrifugal acceleration	3,000 G (5,000 min^{-1})	
Bearing speed	Static	
Bearing fixing	The centrifugal force acts in the radial loading direction of the bearing.	The centrifugal force acts in the axial loading direction of the bearing.
Test time	4 hours : The bearings were weighed every hour and lubricant leakage (weight ratio) was determined.	

(2) Rotating Torque Test

When tested, the required rotating torque level for **NTN** bearings with solid grease utilizing the spot-pack configuration was found to be less than bearings using lithium-diester grease (an acknowledged low torque grease). However, the full-pack configuration exhibited running torque levels greater than those of standard bearings.

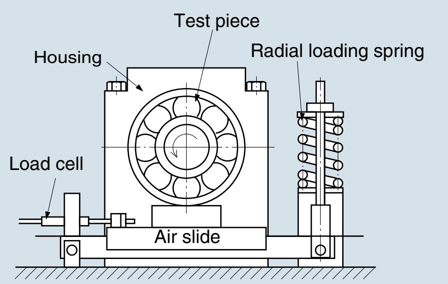

Fig. 3 Torque tester

Table 6 Torque testing conditions

	Testing conditions
Test piece	6204ZZ
Test grease	LP03 and Li greases (30% fill relative to the bearing space capacity, other than for LP03 full-pack configuration)
Bearing load	Radial load; 39 N {4 kgf}
Bearing speed	1,800, 3,600, 7,200 min^{-1}
Measuring method	Measured after rotating torque was stabilized

Table 7 Torque test results

unit $\times 10^{-4}$Nm

Speed (min^{-1})		1800	3600	7200
Li-mineral oil grease		230	385	550
Li-polyol-ester-grease		145	265	383
Li-diester grease		90	315	403
Solid grease	Spot-pack	63	113	190
	Full-pack	340	—	—

(3) Salt Water Test

A salt water endurance test was performed to compare the performance of bearings with solid grease to that of bearings using a conventional lubricant (lithium-mineral oil based grease). As noted in **Table 9**, **NTN** bearings with solid grease were found to out perform standard bearings although some surface deterioration had been detected.

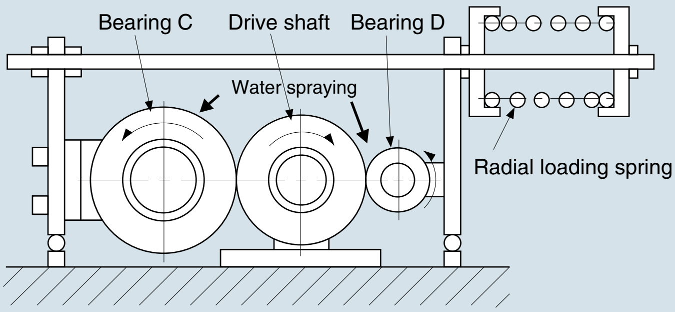

Fig. 4 Salt water testing equipment

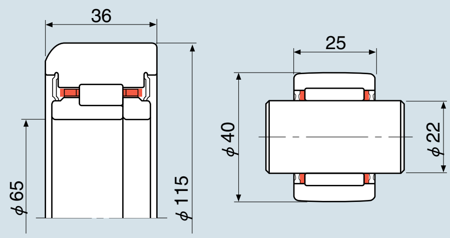

Fig. 5 Test pieces

Table 8 Salt water testing conditions

	Bearing C	Bearing D

6 Stainless steel series prelubricated deep groove ball bearings

1. Product overview

(1) Having an inner ring, outer ring, and retainer each made of a stainless steel, this unique series of contact seal type deep groove ball bearings have a spot-pack configuration with solid grease (LP03).

(2) Bearing accuracy
The dimensional accuracy and running accuracy of this series of bearings are equivalent to JIS class 0 bearings.

(3) Radial internal clearance
The permissible radial internal clearances of this bearing series are summarized in the table below. Note that the values in this table differ from those specified in the JIS (Japanese Industrial Standard) standard.

Unit: μm

Nominal bore diameter mm		Radial internal clearance	
over	incl.	min	max
—	10	6	17
10	18	6	20
18	30	8	22

(4) The indications on the inner and outer rings are as listed below.

● SSN 0 series

Designation	Indication	
	Inner ring	Outer ring
SSN000LL	SS	SS
SSN001LL	SS	SS
SSN002LL	SS	SS
SSN003LL	SS	SMT, SS6003, JAPAN
SSN004LL	SS	SMT, SS6004, JAPAN
SSN005LL	SS	SMT, SS6005, JAPAN
SSN006LL	SS	SMT, SS6006, JAPAN

● SSN 2 series

Designation	Indication	
	Inner ring	Outer ring
SSN200LL	SS	SMT, SS6200, JAPAN
SSN201LL	SS	SMT, SS6201, JAPAN
SSN202LL	SS	SMT, SS6202, JAPAN
SSN203LL	SS	SMT, SS6203, JAPAN
SSN204LL	SS	SMT, SS6204, JAPAN
SSN205LL	SS	SMT, SS6205, JAPAN

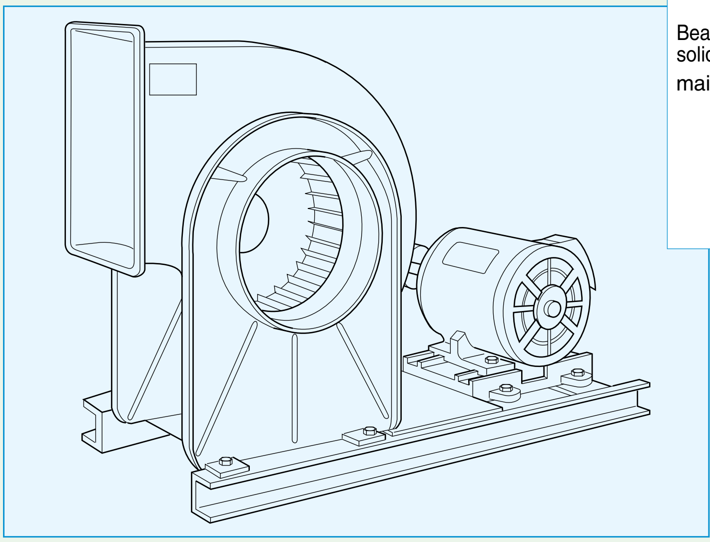
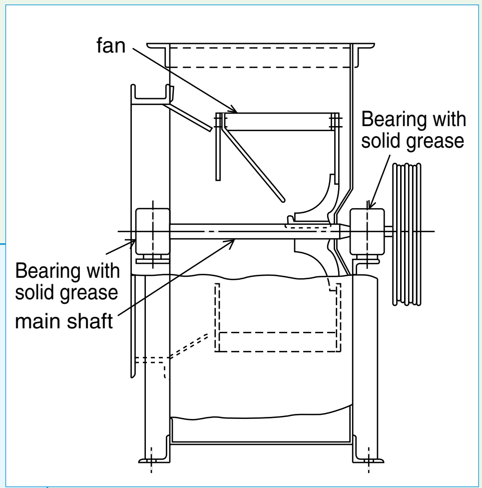
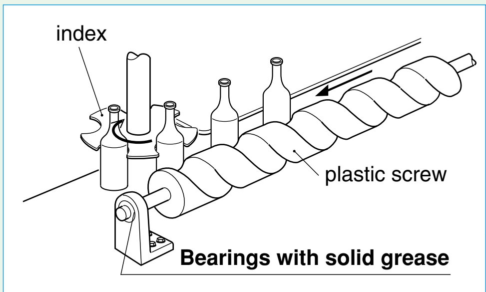
❶ Smallest allowable dimension for chamfer dimension r.
❷ The dimensions with listed basic numbers are identical to the boundary dimensions in JIS B 1512.

Fan blower support bearing

Lubricant suction prevention

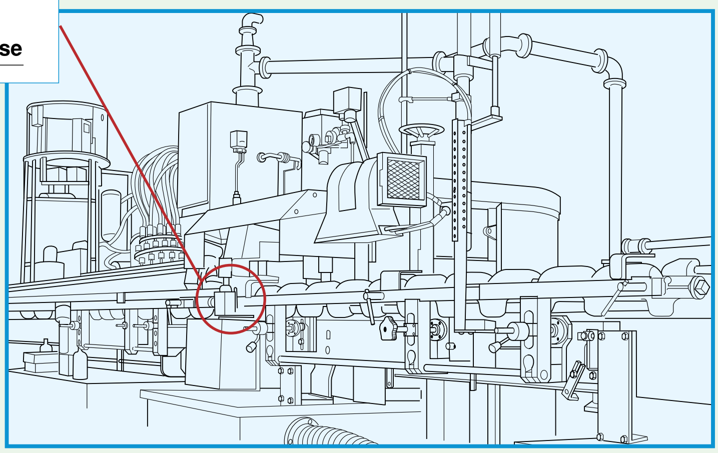






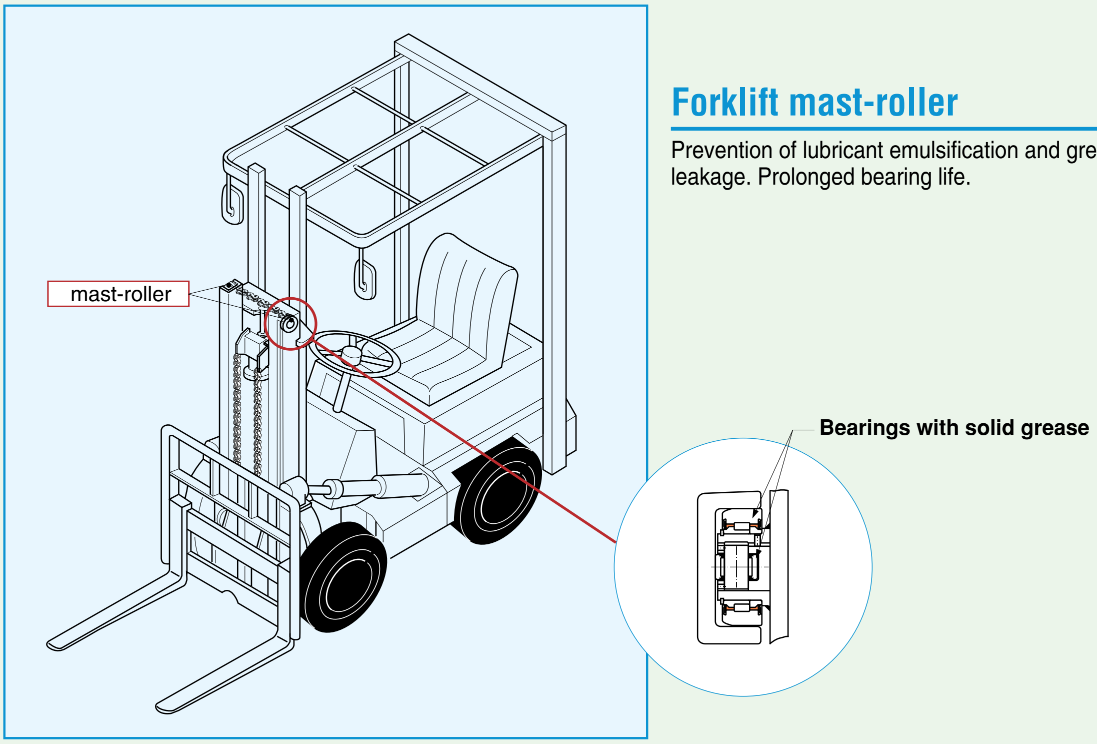
Support bearings for bottle feeder of filler on bottling line

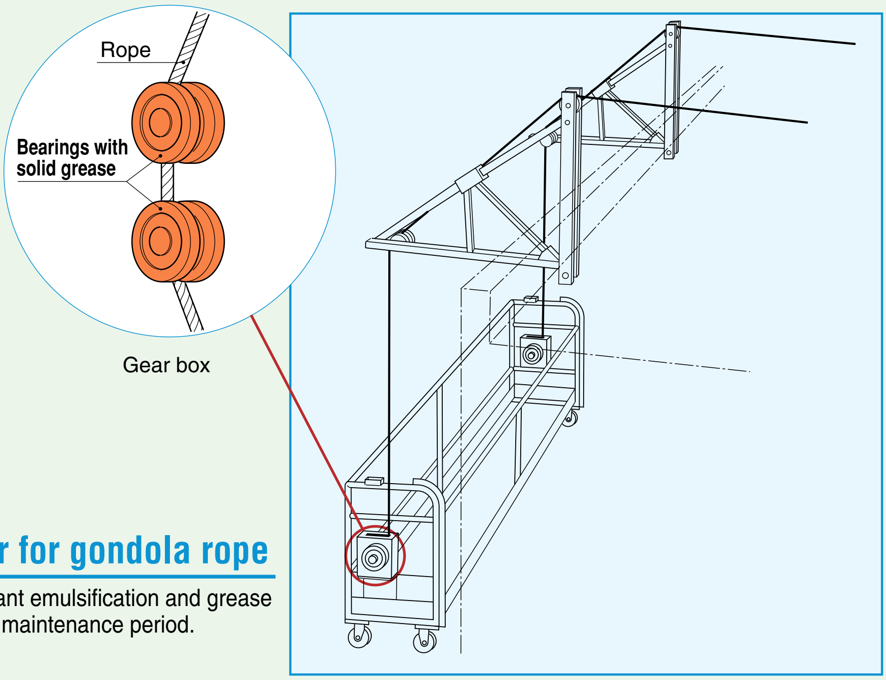
Prevention of lubricant leakage and product contamination



Forklift mast-roller

Prevention of lubricant emulsification and grease leakage. Prolonged bearing life.

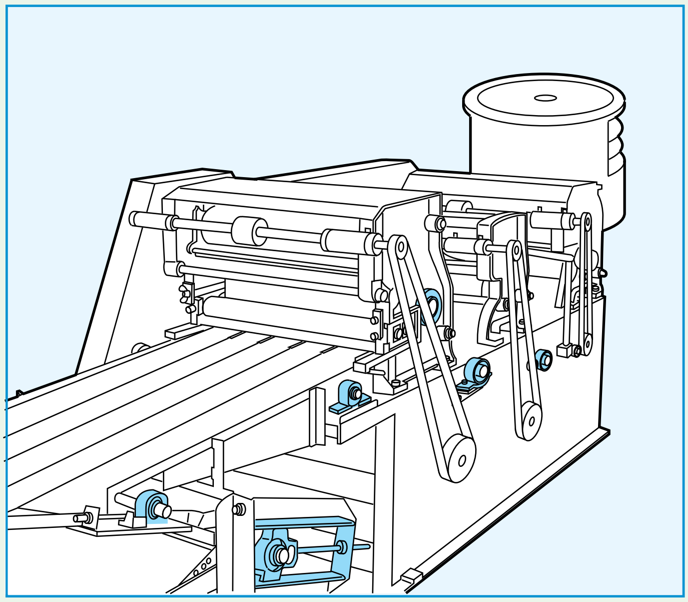




Guide roller for gondola rope

Prevention of lubricant emulsification and grease leakage. Prolonged maintenance period.

Noodle-making machine



Automatic wonton skin making lines

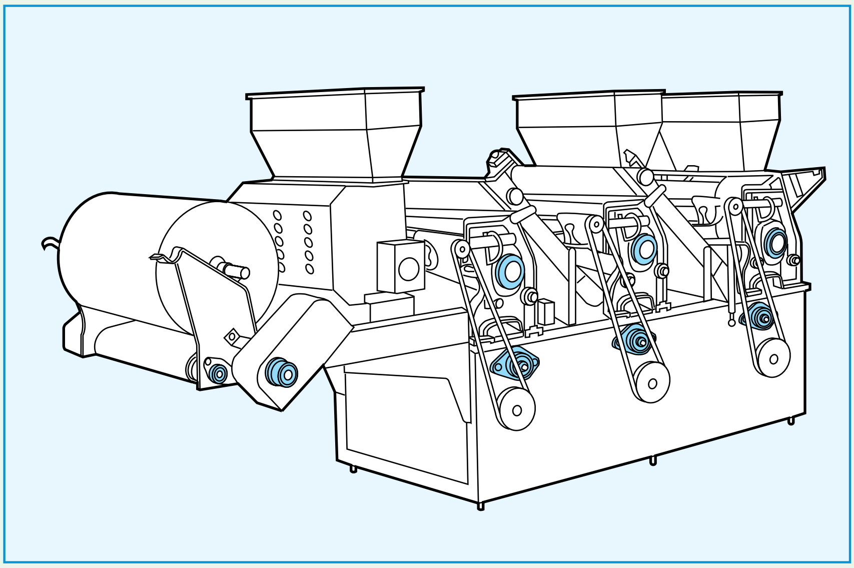


Table 10 Typical applications

Machines	Required characteristics
Cranes, sheaves, conveyors, steel mill rollers, amusement machines, etc.	Bearings with long lubricant life
Fork lift truck mast rollers, conveyors, etc.	Improved dust and water-proofing capability
Wire stranding machines etc.	Prevention of lubricant leakage (i.e. applications where the bearing is required to rotate about an axis other than its own).
Printing presses, office equipment, textile machines, food processing machines, etc.	Prevention of leaked lubricant (clean work environment)
Testing equipment, film stretching machines, etc.	Low torque

CAUTIONS: Avoid use in presence of splashing organic solvent (acetone, benzene, kerosene, etc.)

For New Technology Network

NTN®

Integrated Rotation Sensor Bearings

CAT. No. 3032/E

NTN Integrated Rotation Sensor Bearings

1. This is an integrated product combining a bearing with a rotation sensor that detects the speed and direction of rotation.

2. With a wide variety of models and advanced functions available, these bearings will make your machines more compact and also help in improving their reliability.

In recent years, industrial machines have been using electrical controls that make the machines simpler, allow unmanned operation, and reduce the environment load. In view of this background, many sensors necessary for electrical control are being used, and there is an increased need for bearings with sensors because they simplify installation of sensors and help in making the machines more compact. Therefore, NTN has combined its superior bearing technology and sensor technology to create a series of bearings with rotation sensors.

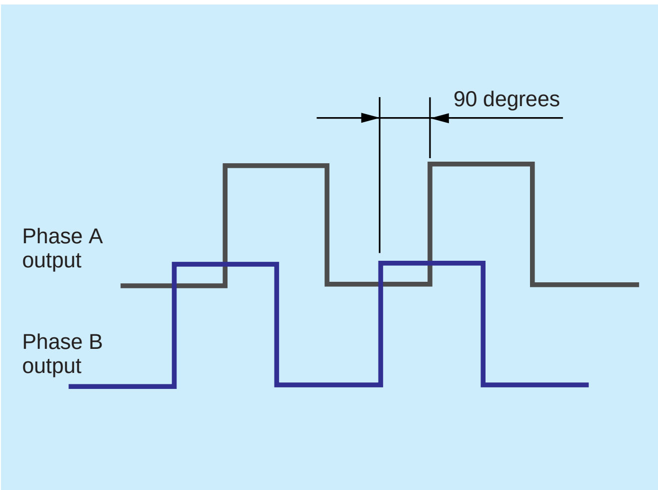
1 Construction and Principles

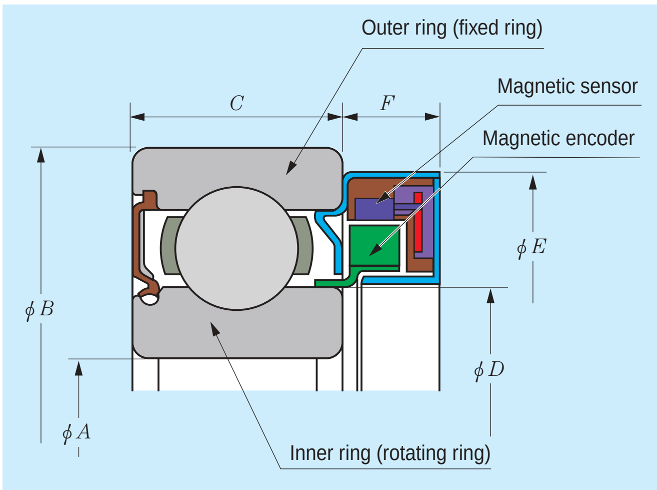
The rotation sensor is made up of a magnetic encoder (a multiple pole magnet) and a magnetic sensor.

The magnetic encoder is fixed to the inner ring (the rotating ring) of the bearing and the magnetic sensor is fixed to the outer ring (the fixed ring).

With the rotation of the shaft (and the inner ring), when the magnetic encoder passes near the magnetic sensor, the magnetic sensor senses changes in the magnetic pole (N pole and S pole) of the magnetic encoder that is opposite to it and outputs a corresponding electrical signal (with a rectangular waveform).

Through numerical processing of these output signals, the rotational speed can be calculated. In addition, because the phase A output and phase B output signals have a mutual electrical phase shift of 90 degrees, the direction of rotation can also be detected.





2 Applications

AC servo motors, DC servo motors, hydraulic motors, etc.

The adoption of **NTN** integrated rotation sensor bearings allows detection of the rotational speeds and rotational directions of motors. There is no need to add an encoder outside the motor, which allows the motor to be more compact.

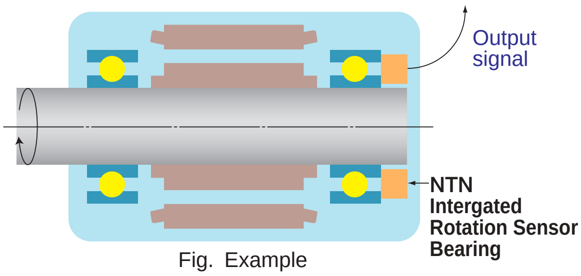


Fig. Example

3 Specifications

Bearing model number	6202	6204	6206	6208	6209
Bearing tolerance class	JIS：Grade 0 ISO：NORMAL				
Bearing inner diameter (mm) :ϕA	15	20	30	40	45
Bearing outer diameter (mm) :ϕB	35	47	62	80	85
Bearing width (mm): : C	11	14	16	18	19
Sensor unit inner diameter (mm) :ϕD	18	29.5	40.6	53	57.3
Sensor unit outer diameter (mm) :ϕE	32	46.6	58	75	77
Sensor unit width (mm) : F	7.5	7.5	7.5	7.5	7.5
Basic dynamic load ratings (kN)	7.75	12.8	19.5	29.1	32.5
Basic static load ratings (kN)	3.6	6.65	11.3	17.8	20.4
Allowed axial load (static) (kN)	1.48	3.08	5.81	11	9.59
Radial internal clearance: C3 (mm)	0.011〜0.025	0.013〜0.028	0.013〜0.028	0.015〜0.033	0.018〜0.036
Lubrication	Grease (Multemp SRL)				
Seal type	LU (Contact seal NBR)				
Input voltage (+Vcc DC)	5〜24				
Number of output pulses	32	48	64	80	80
Number of signal phases	Two phases (phase A and phase B)				
Sensor output accuracy (See the section on "Calculation of Output Waveform Accuracy.")	Adjacent period error: 5% or less				
	Duty cycle: 50 ±15% (35 to 65%)				
	Phase shift between phase A and phase B: 90 ±45 degrees (45 to 135 degrees)				
Type of waveform	Rectangular output waveform (open collector output, protective resistor 100 Ω)				
Connection of wire	Red line: Input voltage +Vcc				
	White line: Output signal phase A				
	Blue line: Output signal phase B				
	Black line: GND				
Wire size	AWG24 (UL)				
Connector	None/Optional				
Wire bending radius (mm)	Minimum radius: 12				
Wire length (mm)	500				
Ambient operating temperature (˚C)	-25 to 120				
Weight (kg) (Reference)	Approx. 0.10	Approx. 0.13	Approx. 0.25	Approx. 0.45	Approx. 0.48

Connect a pull-up resistor between the power supply terminal and the each signal output terminals.
See the "Electrical Circuit" section for the values of the pull-up resistor, and set it so that the sink current is 20 mA or less.

4 Calculation of Output Waveform Accuracy

The accuracy is calculated using the equations below for each output pulse per one rotation.

1. Adjacent period error (%)

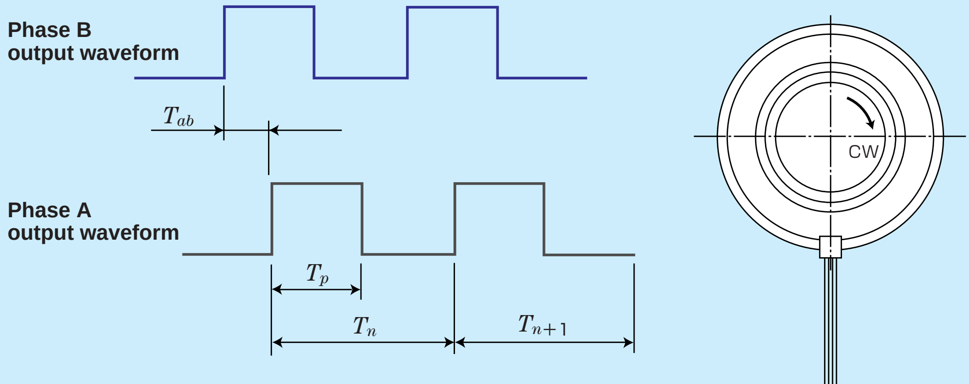
$$=\{|(T_n-T_{n+1})|/T_n\}\times 100$$

2. Duty cycle (%)

$$=(T_p/T_n)\times 100$$

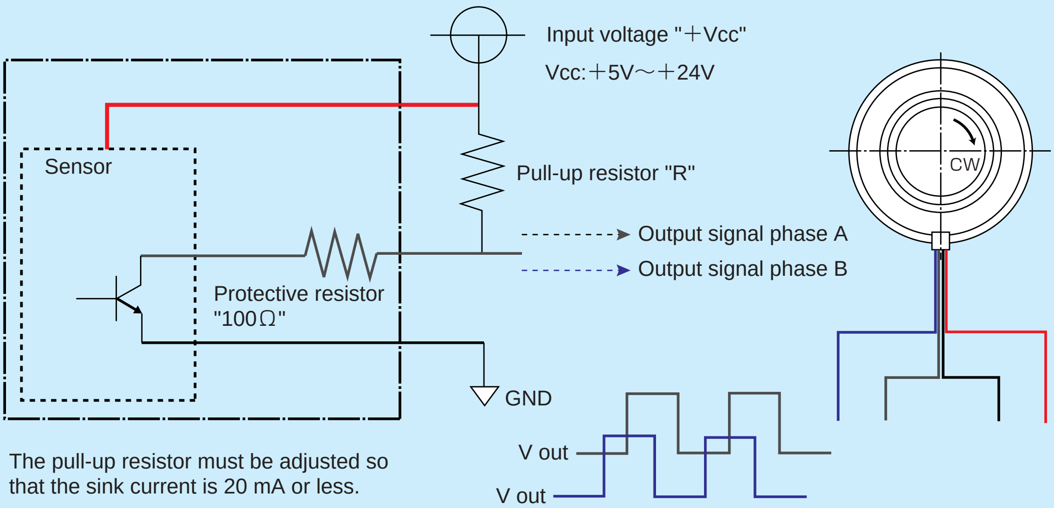
3. Phase shift between phase A and phase B (degrees)

$$=(T_{ab}/T_n)\times 360$$



As viewed from the sensor unit side, when the inner ring is rotated clockwise (CW), the phase B waveform rises before the rise of the phase A waveform.

5 Electrical Circuit



The pull-up resistor must be adjusted so that the sink current is 20 mA or less.

Pull-up Resistor Examples

Input voltage "+Vcc" (DC)	Value of "R"
+5V	270Ω
+9V	470Ω
+12V	680Ω
+24V	1.5kΩ

Caution:

V out (Low) is the voltage value when the sensor operates. (When the waveform is "Low.") This voltage value can be adjusted with the value of the pull-up resistor "R."

V out (Low) is calculated using the following equation:

V out (Low) =Vcc×100／(R+100)+Vce

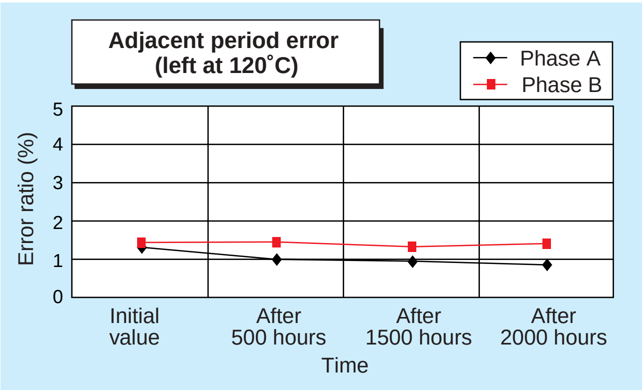
1. Internal protective resistance value: 100 Ω
2. Output saturation voltage for the sensor only. Vce (sat): 0.4 V (max)

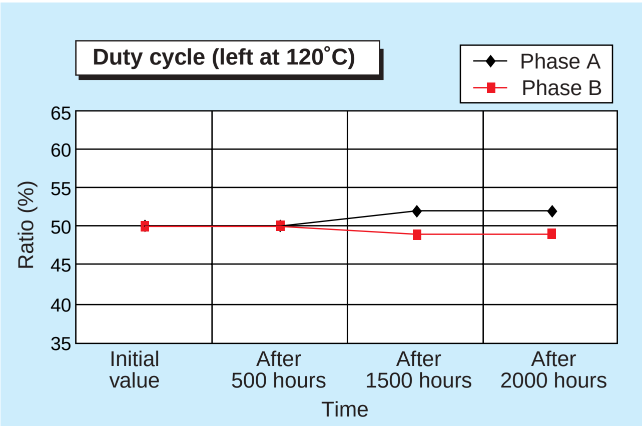
Maximum sink current: 20 mA (both phase A and phase B)

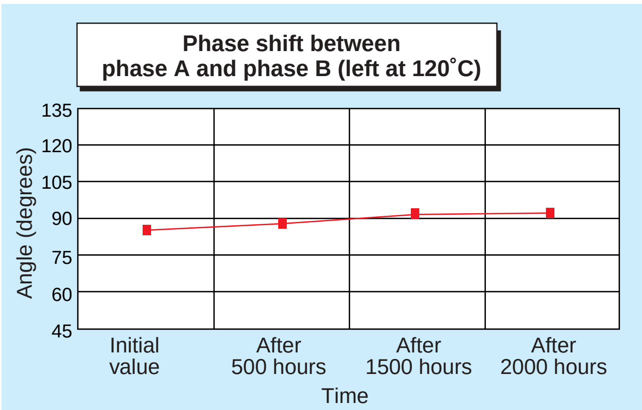
I sink=Vcc／(R+100)≦20mA

6 Reliability Test (Reference)

The signal accuracy measurement data for **NTN** integrated rotation sensor bearings is shown below. Even when kept static for 2,000 hours at 120˚C, the **NTN** integrated rotation sensor bearings have stable signal properties, contributing to improving the reliability of the units in which they are used.







Each measurement is made at room temperature at a speed of 60 min^{-1}.

7 EMC Standard Test (Reference)

Power supply frequency and magnetic field standard: EN61000-4-8

Handling Precautions

1. Do not let the ends of the wires come into contact with anything that has accumulated static electricity. It is possible that the static electricity could damage the bearings.
2. Do not build these bearings into machinery that produces electromagnetic waves. Also, do not use them in areas where electromagnetic waves are produced. It is possible that electromagnetic waves could damage the bearings.
3. Do not use these bearings in areas where they may have impact on human life.
4. In the unlikely event of a sensor signal error, be sure to take safety measures, such as a backup system, etc.
5. Do not apply any load to the sensor unit.
6. Do not subject the integrated sensor bearings to any shock.
7. Do not put any load to the wires. Also, do not carry the bearings by the wires.
8. Do not use the integrated sensor bearings in environments where they can come into contact with or be penetrated by water, oil or foreign matter (steel powder, dust).

Notes

1. These bearings are compatible with RoHS instructions (2002/95/EC).
2. **NTN has "high temperature application" models for use in locations where the ambient operating temperature exceeds 120˚C. Please contact your NTN branch office or sales office for details.**
3. **With respect to "Ferromagnetic Field Resistant application" models for use in areas with strong magnetic fields, such as near high output motors, please contact your NTN branch office or sales office for details.**
4. If you must use these bearings for purposes other than those specified in this catalog, please contact your nearest **NTN** sales office.

Warranty

NTN warrants, to the original purchaser only, that the delivered product which is the subject of this sale (a) will conform to drawings and specifications mutually established in writing as applicable to the contract, and (b) be free from defects in material or fabrication. The duration of this warranty is one year from date of delivery. If the buyer discovers within this period a failure of the product to conform to drawings or specifications, or a defect in material or fabrication, it must promptly notify **NTN** in writing. In no event shall such notification be received by **NTN** later than 13 months from the date of delivery. Within a reasonable time after such notification, **NTN** will, at its option, (a) correct any failure of the product to conform to drawings, specifications or any defect in material or workmanship, with either replacement or repair of the product, or (b) refund, in part or in whole, the purchase price. Such replacement and repair, excluding charges for labor, is at **NTN**'s expense. All warranty service will be performed at service centers designated by **NTN**. These remedies are the purchaser's exclusive remedies for breach of warranty.

NTN does not warrant (a) any product, components or parts not manufactured by **NTN**, (b) defects caused by failure to provide a suitable installation environment for the product, (c) damage caused by use of the product for purposes other than those for which it was designed, (d) damage caused by disasters such as fire, flood, wind, and lightning, (e) damage caused by unauthorized attachments or modification, (f) damage during shipment, or (g) any other abuse or misuse by the purchaser.

THE FOREGOING WARRANTIES ARE IN LIEU OF ALL OTHER WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE.

In no case shall **NTN** be liable for any special, incidental, or consequential damages based upon breach of warranty, breach of contract, negligence, strict tort, or any other legal theory,and in no case shall total liability of **NTN** exceed the purchase price of the part upon which such liability is based. Such damages include, but are not limited to, loss of profits, loss of savings or revenue, loss of use of the product or any associated equipment, cost of capital, cost of any substitute equipment, facilities or services, downtime, the claims of third parties including customers, and injury to property. Some states do not allow limits on warranties, or on remedies for breach in certain transactions. In such states, the limits in this paragraph and in paragraph (2) shall apply to the extent allowable under case law and statutes in such states.

Any action for breach of warranty or any other legal theory must be commenced within 15 months following delivery of the goods.

Unless modified in a writing signed by both parties, this agreement is understood to be the complete and exclusive agreement between the parties, superceding all prior agreements, oral or written, and all other communications between the parties relating to the subject matter of this agreement. No employee of **NTN** or any other party is authorized to make any warranty in addition to those made in this agreement.

This agreement allocates the risks of product failure between **NTN** and the purchaser. This allocation is recognized by both parties and is reflected in the price of the goods. The purchaser acknowledges that it has read this agreement, understands it, and is bound by its terms.

TECHNICAL DATA CONTENTS

1. Classification of Precision Rolling Bearings for Machine Tools

① Main spindle bearings

Table .1 Types of precision rolling bearings for machine tools

Bearing type		Cross section	Bearing type	Bearing bore mm	Contact angle	Remarks	Page
 Angular contact ball bearing	Standard		78C	φ25～φ170	15°	● A bearing type code containing a suffix U means an ULTAGE ULTAGE series bearing. Optimized interior structure and resin cage help positively inhibit temperature rise (applicable to 79 and 70 types with bore diameter of 10 to 130 mm). ● Bearings with prefix 5S have ceramic balls.	84 ～ 111
			79 (U), 5S-79 (U)	φ10～φ170	15°, 25°, 30°		
			70 (U), 5S-70 (U)	φ10～φ200	15°, 25°, 30°		
			72C	φ10～φ130	15°		
	High-speed		2LA-HSE9U 5S-2LA-HSE9	φ50～φ170	15°, 20°, 25°	● ULTAGE ULTAGE series ● Use of special material and introduction of surface modification contribute to much improved wear resistance and anti-seizure property. ● Optimized specifications for the interior structure lead to higher speed, rigidity and reliability. ● Bearings with prefix 5S have ceramic balls.	112 ～ 135
			2LA-HSE0 5S-2LA-HSE0				
	Super high-speed		5S-2LA-HSF0	φ50～φ100	25°	● ULTAGE ULTAGE series ● Maintaining the advantages of HSE type, this type has small diameter ceramic balls to achieve higher speed and limited heat buildup. ● Bearings with prefix 5S have ceramic balls.	136 ～ 137
	Eco-friendly		5S-2LA-HSL9U	φ50～φ170	20°, 25°	● ULTAGE ULTAGE series ● These bearings are identical to the HSE and HSF types except in that they are air-oil lubrication designs that have an eco-friendly nozzle. ● Featuring lower noise, reduced air and oil consumption, they positively improve operating environments and reduce energy consumption. ● Bearings with prefix 5S have ceramic balls.	138 ～ 147
			5S-2LA-HSL0				
			5S-2LA-HSFL0	φ50～φ100	25°		
	HSE with Lubrication hole		5S-2LA-HSEW9U	φ50～φ100	20°, 25°	● ULTAGE ULTAGE series ● High speed angular contact ball bearings with lubrication hole on outer ring, designed especially for air-oil lubrication based on HSE type. These bearings have an effect on compact design and high rigidity of spindle. Air flow rate and oil consumption can be reduced. ● Bearings with prefix 5S have ceramic balls.	148 ～ 155
			5S-2LA-HSEW0				
	Standard	 Non-contact sealed type	79 LLB 5S-79 LLB	φ10～φ50	15°, 25°	● ULTAGE ULTAGE series ● Featuring a two-side non-contact seal design and a special grease, these bearings are a dedicated grease lubricated type that has achieved limited heat buildup through optimization of the interior structure. ● Bearings with prefix 5S have ceramic balls.	156 ～ 171
			70 LLB 5S-70 LLB				
	High-speed	 Non-contact sealed type	2LA-BNS9 LLB 5S-2LA-BNS9 LLB	φ45～φ100	15°, 20°, 25°	● ULTAGE ULTAGE series ● Maintaining the advantages of HSE type, this dedicated grease lubricated type has an improved interior design (grease reservoir, both -side non-contact seal and special grease) to extend grease life. ● Bearings with prefix 5S have ceramic balls.	172 ～ 195
			2LA-BNS0 LLB 5S-2LA-BNS0 LLB				
			BNT9 5S-BNT9	φ10～φ65	15°	● Angular contact ball bearing series for grinding machines/motors. ● All variants are flush ground. ● Bearings with prefix 5S have ceramic balls.	196 ～ 207
			BNT0 5S-BNT0	φ10～φ70			
			BNT2 5S-BNT2	φ10～φ80			
 Double-row cylindrical roller bearing			NN49 (K)	φ100～φ320	――	● The bearing clearance can be either interchangeable radial clearance or non-interchangeable radial clearance. ● A variant (K) is available with a tapered bore to accommodate a tapered shaft. ● A bearing type code containing a suffix T6 means an ULTAGE ULTAGE series bearing. Optimized interior structure and resin cage help high speed and positively inhibit temperature rise (applicable to NN30 types with bore diameter of 65 to 130 mm).	224 ～ 229
			NN30 (K) NN30HS (K)	φ25～φ60 φ140～φ460			
			NN30HST6 (K) NN30HSRT6 (K)	φ65～φ130			
			NNU49 (K)	φ100～φ500	――		

Bearing type	Cross section	Bearing type	Bearing bore mm	Contact angle	Remarks	Page
 Single-row cylindrical roller bearing	Standard 	**N10HS (K)**	ϕ30〜ϕ160	———	● The boundary dimensions of the N10HS(K) high-speed single-row cylindrical roller bearing are the same as those of the N10(K). Only the bearing clearance is non-interchangeable. ● A ceramic-roller-type (5S-N10) is available on request.	230 〜 233
	High-speed 	**N10HSR (K)**	ϕ55〜ϕ100	———	● *ULTAGE* ULTAGE series ● Optimized internal design allows higher speed and results in lower temperature rise. ● The cage is made of a special resin to cope with a high-speed operation. ● The allowable maximum speed is higher than that of the conventional high-speed cylindrical roller bearing N10HS(K).	234 〜 235
	Eco-friendly 	**N10HSL (K)**	ϕ55〜ϕ100	———	● *ULTAGE* ULTAGE series ● This is a dedicated air-oil lubricated type identical to the N10HSR(K) type except in that it incorporates an eco-friendly nozzle. ● Still maintaining the high-speed performance of the N10HSR(K) type, this type boasts lower noise, reduced air and oil consumption, and positively improves operating environments and reduces energy consumption.	236 〜 237
 Plug gage Ring gage Taper gage		**Plug gage TA**	ϕ30〜ϕ160	———	● Taper gage for N10-HS(K) single-row cylindrical roller bearing and NN30(K) double-row cylindrical roller bearing.	238
		Ring gage TB	ϕ30〜ϕ160			
 Residual internal clearance adjustment gauge		**SB**	ϕ35〜ϕ160	———	● Clearance gage for N10-HSK(K), N10-HSR(K) single-row cylindrical roller bearing and NN30(K), NN30HS(K) double-row cylindrical roller bearing.	239
 Adjustable preload bearing unit		**Adjustable preload bearing unit**	———	———	● Fixed position adjustable preload bearing unit. ● Incorporation of an adjustable preload sleeve and a duplex angular ball bearing allows the user to adjust the preload of an angular ball bearing in a wider range from a light preload to a heavy preload. ● Fixed position preload leads to a greater rigidity.	—
 Double-direction angular contact thrust ball bearing		**5629 (M)**	Small-size ϕ100〜ϕ320 Large-size (M) ϕ104〜ϕ330	60°	● The small bearing is used on a cylinder bore or smaller-diameter side of a tapered bore of the NNU49, NN49 or NN30 double-row cylindrical roller bearing; the large bearing (suffix M) is used on the large hole side of a tapered bore.	250 〜 253
		5620 (M)	Small-size ϕ25〜ϕ320 Large-size (M) ϕ27〜ϕ330			
 Angular contact ball bearing for axial load		**HTA9U**	ϕ100〜ϕ320	30°, 40°	● *ULTAGE* ULTAGE series ● HTA9DB series bearings are fully compatible with 5629 series bearings.	254 〜 265
		HTA0U **5S-HTA0U**	ϕ25〜ϕ320 ϕ25〜ϕ130		● *ULTAGE* ULTAGE series ● HTA0DB series bearings are fully compatible with 5620 series bearings.	
 Tapered roller bearings		**329**	ϕ50〜ϕ190	Nominal contact angle of 10° or greater, 17° or smaller	● Thin-wall type, ISO-compatible metric series.	270 〜 273
		320	ϕ20〜ϕ170			

② Ball screw support bearings

Bearing type	Cross section	Bearing type	Bearing bore mm	Contact angle	Remarks	Page
 Angular contact thrust ball bearing for ball screws		**BST** **2A-BST** Open type **BST LXL/L588** **2A-BST LXL/L588** Light-contact sealed type	φ17～φ55	60°	● *ULTAGE* ULTAGE series ● Surface modification treatment on the bearing ring raceways has led to a longer bearing life and much improved fretting resistance. ● Owing to prelubrication with a special grease, the sealed type boasts a longer bearing life and simpler maintenance work. ● All variants are flush-ground and are provided with a standard preload.	290 ∫ 295
 Ball screw support double row thrust angular contact ball bearing unit		**BSTU LLX/L588** Light-contact sealed type	φ20～φ100	60°	● *ULTAGE* ULTAGE series. ● Greater high-load capacity with optimizations made to the internal bearing design. ● Use of newly developed light-contact seal to achieve both low torque and high dust resistance. ● Long operating life, and use of special grease with high fretting resistance. ● Outer ring mounting hole, and sealed grease lubrication groove for easier handling.	296 ∫ 299
 Angular contact ball bearing for ball screws		**HT**	φ6～φ40	30°	● The allowable axial load of this bearing type is greater owing to the improved interior design.	300 ∫ 301
 Needle roller bearings with double-direction thrust needle roller bearing		**AXN**	φ20～φ50	——	● A clearance remains between the inner ring of radial bearing and the inner rings of both thrust bearings, allowing the user to determine the preload by, for example, tightening a nut etc. ● The targeted preload is attained based on the starting torque. ● The bearing clearance on certain preloaded bearings is controlled in advance so that an intended preload is attained by fully tightening the inner rings on both thrust bearing with nuts, or equivalent means.	302 ∫ 303
 Cylindrical roller bearings with double-direction thrust needle roller bearing		**ARN**	φ20～φ70	——		304 ∫ 305

2. Bearing Selection and Shaft & Housing Design

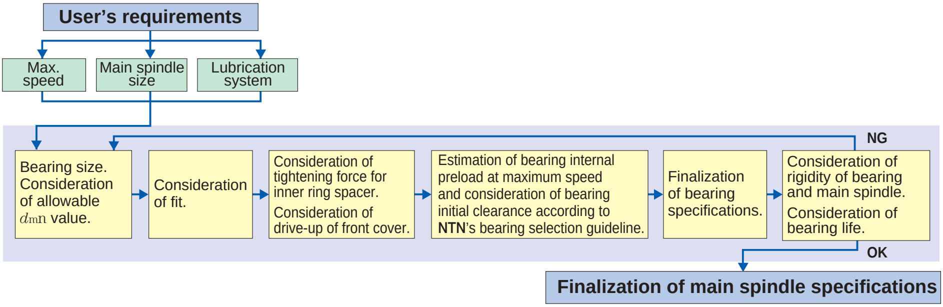
① Bearing selection

Generally, the optimal bearing must be selected to suit the nature of the machine, the area within the machine, the spindle specification, bearing type, lubrication system and drive system of the intended machine through considerations of the design life, precision, rigidity and critical speed, etc. of the bearing. **Table 2.1** summarizes a typical bearing selection procedure, and **Table 2.2** gives an example flowchart according to which considerations are made to select an optimal main spindle bearing for a machine tool.

Table 2.1 Bearing selection procedure

Step	Items being considered	Items being confirmed
Confirm operating conditions of bearing and consider bearing type.	● Function and construction of components to house bearings ● Bearing mounting location ● Dimensional limitations ● Magnitude and direction of bearing load ● Magnitude of vibration and shock load ● Shaft speed ● Bearing arrangement (fixed side, floating side) ● Noise and torque of the bearing ● Bearing operating temperature range ● Bearing rigidity ● Installation / disassembly requirements ● Maintenance and inspection ● Cost-effectiveness ● Allowable misalignment of inner/outer rings	Determine bearing type and arrangement.
Select bearing dimensions.	● Design life of components to house bearings ● Dynamic/static equivalent load conditions ● Safety factor So ● Allowable speed ● Allowable axial load	Determine bearing dimensions.
Select bearing tolerances.	● Shaft runout tolerances ● Torque fluctuation ● High-speed operation	Decide bearing grade.
Select bearing internal clearance.	● Material and shape of shaft and housing ● Fit ● Temperature difference between inner and outer rings ● Allowable misalignment of inner/outer rings ● Magnitude and nature of load ● Amount of preload	Decide bearing internal clearance.
Select cage.	● Rotational speed ● Noise level ● Vibration and shock load ● Lubrication	Cage type
Select lubrication method.	● Operating temperature ● Rotational speed ● Lubrication method ● Sealing method ● Maintenance and inspection	Decide lubrication method, lubricant, and sealing method.
Consider special specifications.	● Operating conditions (special environments: high or low temperature, chemical) ● Requirement for high reliability	Decide special bearing specifications.
Select installation and disassembly procedures.	● Mounting dimensions ● Installation and disassembly procedures	Decide installation and disassembly procedures.

Table 2.2 Bearing selection procedure



The articles necessary for basic considerations in selecting an optimal main spindle bearing for machine tool are summarized in **Table 2.3.**

Table 2.3 Selection procedure for bearings for main spindles of machine tools

(1) Type of Machine	NC Lathe, machining center, grinding machine, etc.
(2) Main spindle orientation	Vertical, horizontal, variable-direction, inclined, etc.
(3) Diameter and size of main spindle	#30, #40, #50, etc.
(4) Shape and mounting-related dimensions of main spindle	 **Fig. 2.1 Main spindle shape and mounting-related dimensions (example)**
(5) Intended bearing type, bearing size, and preloading method	Front (angular contact type, cylindrical roller type) or rear (angular contact type, cylindrical roller type) preloading system (fixed-position preloading, fixed-pressure preloading)
(6) Slide system free side	Cylindrical roller bearing, ball bushing (availability of cooling)

② Bearing accuracy

■Bearing accuracy

Accuracies of rolling bearings, that is, dimensional accuracy and running accuracy of rolling bearings are defined by applicable ISO standards and JIS B 1514 standard (Rolling bearings - Tolerances) (**Tables 2.4** and **2.5**). The dimensional accuracy governs the tolerances that must be satisfied when mounting a bearing to a shaft or housing, while the running accuracy defines a permissible run-out occurring when rotating a bearing by one revolution. Methods for measuring the accuracy of rolling bearings (optional methods) are described in JIS B 1515 (Measuring methods for rolling bearings). **Table 2.6** summarizes some typical methods for measuring running accuracy of rolling bearings.

Table 2.4 Bearing types and applicable tolerance

Bearing type		Applicable standard	Tolerance class				
Angular contact ball bearings		JIS B 1514 (ISO492)	Class 0	Class 6	Class 5	Class 4	Class 2
Cylindrical roller beargns			Class 0	class 6	Class 5	Class 4	Class 2
Needle roller bearings			Class 0	class 6	Class 5	Class 4	—
Tapered roller bearings	Metric	JIS B 1514	Class 0,6X	class 6	Class 5	Class 4	—
	Inch	ANSI/ABMA Std.19	Class 4	Class 2	Class 3	Class 0	Class 00
	J series	ANSI/ABMA Std.19.1	Class K	Class N	Class C	Class B	Class A
Double row angular contact thrust ball bearings		**NTN** standard	—	—	Class 5	Class 4	—

Table 2.5. Comparison of tolerance classifications of national standards

Standard	Applicable standerd	Tolerance Class					Bearing Types
Japanese industrial standard (JIS)	JIS B 1514	Class 0,6X	Class 6	Class 5	Class 4	Class 2	All type
International Organization for Standardization (ISO)	ISO 492	Normal class Class 6X	Class 6	Class 5	Class 4	Class 2	Radial bearings
	ISO 199	Normal Class	Class 6	Class 5	Class 4	—	Thrust ball bearings
	ISO 578	Class 4	—	Class 3	Class 0	Class 00	Tapered roller bearings (Inch series)
	ISO 1224	—	—	Class 5A	Class 4A	—	Precision instrument bearings
Deutsches Institut fur Normung(DIN)	DIN 620	P0	P6	P5	P4	P2	All type
American National Standards Institute (ANSI)	ANSI/ABMA Std.20 ❶	ABEC-1 RBEC-1	ABEC-3 RBEC-3	ABEC-5 RBEC-5	ABEC-7	ABEC-9	Radial bearings (Except tapered roller bearings)
American Bearing Manufacturer's Association (ABMA)	ANSI/ABMA Std.19.1	Class K	Class N	Class C	Class B	Class A	Tapered roller bearings (Metric series)
	ANSI/ABMA Std.19	Class 4	Class 2	Class 3	Class 0	Class 00	Tapered roller bearings (Inch series)

❶ "ABEC" is applied for ball bearings and "RBEC" for roller bearings.
Notes 1: JIS B 1514, ISO 492 and 199, and DIN 620 have the same specification level.
2: The tolerance and allowance of JIS B 1514 are slightly different from those of ABMA standards.

To attain a higher level of running accuracy required of a main spindle of machine tool, a high-precision bearing that satisfies the user's main spindle specifications must be chosen. Usually, a high-precision bearing per JIS accuracy class 5, 4 or 2 is selected according to an intended application. In particular, the radial run-out, axial run-out and non-repetitive run-out of a main spindle bearing greatly affect the running accuracy of the main spindle and therefore have to be strictly controlled. With the recent super high-precision machine tools, the control of N.R.R.O. (Non-Repetitive Run-Out) has increasing importance, and the main spindle on a turning machine or machining center incorporates an N.R.R.O. accuracy controlled bearing. For further information about N.R.R.O., refer to the following section. Note that to attain a higher accuracy with a main spindle, careful considerations need to be exercised for the accuracies (circularity, cylindricity, coaxiality) of machine components other than a bearing (shaft, housing) as well as machining method and finish accuracy of the shaft and housing. For the information about the accuracies of shaft and housing, refer to a section given later.

Table 2.6 Measuring methods for running accuracies

Characteristic tolerance	Measurement method		
Inner ring radial runout (K_{ia})			Radial runout of the inner ring is the difference between the maximum and minimum reading of the measuring device when the inner ring is turned one revolution.
Outer ring radial runout (K_{ea})			Radial runout of the outer ring is the difference between the maximum and minimum reading of the measuring device when the outer ring is turned one revolution.
Inner ring axial runout (S_{ia})			Axial runout of the inner ring is the difference between the maximum and minimum reading of the measuring device when the inner ring is turned one revolution.
Outer ring axial runout (S_{ea})			Axial runout of the outer ring is the difference between the maximum and minimum reading of the measuring device when the outer ring is turned one revolution.
Inner ring side runout with bore (S_d)			Inner ring side runout with bore is the difference between the maximum and minimum reading of the measuring device when the inner ring is turned one revolution together with the tapered mandrel.
Outer ring outside surface inclination (S_D)			Outer ring outside surface inclination is the difference between the maximum and minimum reading of the measuring device when the outside ring is turned one revolution along the reinforcing plate.

■N.R.R.O. (Non-Repetitive Run-Out) of bearing

Accuracies of rolling bearings are defined by applicable ISO standards and a JIS (Japanese Industrial Standard) standard, wherein the accuracies are discussed under the descriptions of radial run-out (K_{ia}), axial run-out (S_{ia}), etc. According to the methods for measuring running accuracies in **Table 2.6**, run-out is read by turning a bearing by only one revolution (each reading is synchronized with the revolution of the bearing being analyzed).

In fact, however, a rolling bearing for machine tool is used in a continuous revolving motion that involves more than one revolution. As a result, the actual run-out accuracy with a rolling bearing includes elements that are not synchronous with the revolution of the bearing (for example, a difference in diameter among rolling elements involved, as well as roundness on the raceway surfaces of inner ring and outer ring), causing the trajectory of plotting with running accuracies to vary with each revolution.

The run-out of an element not in synchronization with the revolutions of bearing is known as N.R.R.O. (Non-Repetitive Run-Out) and is equivalent to the amplitude in the Lissajous figure illustrated in **Fig. 2.3**.

The effect of N.R.R.O. on a rolling bearing onto the accuracies is illustrated in **Fig. 2.4** by taking a main spindle of turning machine as an example.

This diagram illustrates a machining process where the outside surface of a work piece mounted to the main spindle is shaved by a turning operation. If the outside surface is cut with a new trajectory with every revolution, the outside shape of work piece will be distorted. Furthermore, if the accuracies of shaft and housing are not high enough or bearings are assembled onto the shaft and/or housing improperly, the bearing ring can be deformed, possibly leading to a run-out that is not in synchronization with the revolutions of bearing.

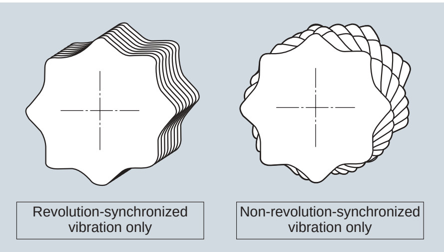

Fig. 2.2

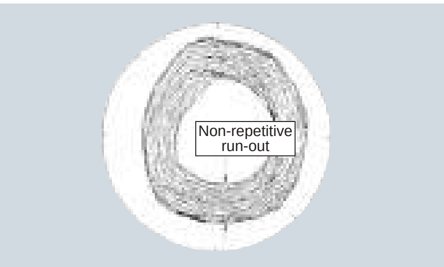

Fig. 2.3 Lissajous figure

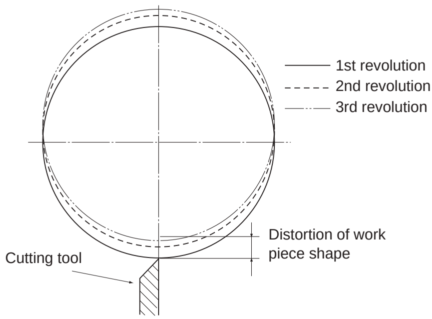

Fig. 2.4 Model of cutting operation

■Accuracies of shaft and housing

Depending on the fit of a bearing to a shaft and a housing, the bearing internal clearance can vary. For this reason, an adequate bearing fit has to be attained so that the bearing can perform as designed. (Refer to the recommended fit section.)

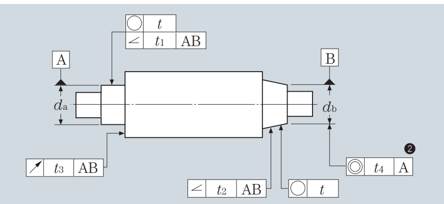
Also, the axial tightening torque on a bearing needs to be considered. To avoid deformation of bearing raceway surface owing to axial tightening of the bearing, it is necessary to carefully determine the dimensions of components associated with a tightening force the magnitude of tightening force and the number of tightening bolts.

The clearance on a tapered bore cylindrical roller bearing is adjusted by changing the drive-up to the taper. Because of this, the critical factors associated with an appropriate fit of a bearing to a shaft and/or a housing are the dimensional accuracies of the taper, contact surface on the taper, and the squareness of the end face of the inner ring relative to the shaft centerline during the drive-up process.

Typical accuracy values for a spindle and housing are summarized in **Tables 2.7** and **2.8**.

Typical accuracy for spindle

Table 2.7 Form accuracy of spindle ❶

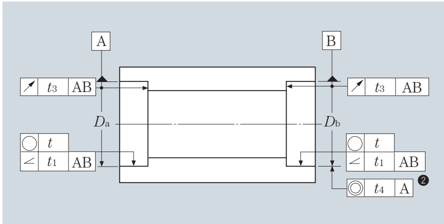


Accuracy	Symbol	Tolerance❸	Fundamental permissible tolerance IT		
			P5	P4	P2
Deviation from circular form	○	t	IT3/2	IT2/2	IT0❹/2
Angularity	∠	t_1	IT3/2	IT2/2	IT0❹/2
	∠	t_2	—	IT3/2	IT2/2
Run out	↗	t_3	IT3	IT3	IT2
Eccentricity	◎	t_4	IT5	IT4	IT3

❶ The form tolerance, symbol, and reference face of spindle are in accordance with ISO R1101.
❷ The length of the bearing fit surface is often too small to measure concentricity. Therefore, this criterion applies only when the fit surface has a width sufficient as a reference face.
❸ When determining a tolerance for permissible form accuracy, the reference dimensions used are shaft diameters d_a and d_b.
For example, when using a JIS class 5 bearing for a dia. 50 mm shaft, the tolerance of roundness is t = IT3/2 = 4/2=2 μm.
❹ IT0 is preferred if the diameter tolerance of the bearing fit surface is IT3.

Typical accuracy for housing

Table 2.8 Form accuracy of housing ❶



Accuracy	Symbol	Tolerance❸	Fundamental permissible tolerance IT		
			P5	P4	P2
Deviation from circular form	○	t	IT3/2	IT2/2	IT1/2
Angularity	∠	t_1	IT3/2	IT2/2	IT1/2
Run out	↗	t_3	IT3	IT3	IT2
Eccentricity	◎	t_4	IT5	IT4	IT3

❶ The form tolerance, symbol and reference face of the housing are in accordance with ISO R1101.
❷ The length of the bearing fit surface is often too small to measure concentricity. Therefore, this criterion applies only when the fit surface has a width sufficient as a reference face.
❸ Housing bore diameters D_a and D_b are the reference dimensions used when the tolerance for permissible form accuracy are determined.
For example, when a JIS class 5 bearing is used for a housing with a 50 mm inside bore, the tolerance of roundness is t = IT3/2 = 5/2 = 2.5 μm.

Fundamental tolerance IT

Table 2.9 Fundamental tolerance IT

Classification of nominal dimension mm		Fundamental tolerance IT value μm					
over	incl.	IT0	IT1	IT2	IT3	IT4	IT5
6	10	0.6	1	1.5	2.5	4	6
10	18	0.8	1.2	2	3	5	8
18	30	1	1.5	2.5	4	6	9
30	50	1	1.5	2.5	4	7	11
50	80	1.2	2	3	5	8	13
80	120	1.5	2.5	4	6	10	15
120	180	2	3.5	5	8	12	18
180	250	3	4.5	7	10	14	20
250	315	4	6	8	12	16	23
315	400	5	7	9	13	18	25
400	500	6	8	10	15	20	27

Note) For machine tool spindles, the shaft hardness is recommended to be at least HRC50 and the housing is recommended to be at least HRC30 to assist bearing replacement during repairs.

③ Bearings and rigidity

The rigidity of the main spindle of a machine tool is associated with both bearing rigidity and shaft rigidity. Bearing rigidity is typically governed by the elastic deformation between the rolling elements and raceway surface under load. Usually, bearings are preloaded in order to increase the rigidity.

Under same loading conditions, a roller bearing has a higher rigidity than a ball bearing of the same size. However, having sliding portions, a roller bearing is disadvantageous in supporting a high-speed shaft.

Shaft rigidity is greater with a larger shaft diameter. However, the supporting bearing must have a sufficient size and its $d_m n$ value (pitch center diameter across rolling elements d_m [mm] multiplied by speed [min^{-1}]) must be accordingly greater. Of course, a larger bearing is disadvantageous for high-speed applications.

To sum up, the rigidity required of the shaft arrangement must be considered before the bearing rigidity (bearing type and preload) and shaft rigidity are determined.

■Bearings rigidity

The rigidity of a bearing built into a spindle directly affects the rigidity of the spindle.

In particular, a high degree of rigidity is required of the main spindle of a machine tool to ensure adequate productivity and accurate finish of workpieces.

Bearing rigidity is governed by factors such as the following:

(1) Types of rolling elements
(2) Size and quantity of rolling elements
(3) Material of rolling elements
(4) Bearing contact angle
(5) Preload on bearing

■Type of rolling elements (roller or ball)

The surface contact pattern of the rolling element and raceway is line contact with a roller bearing, while a ball bearing is point contact. As a result, the dynamic deformation of a bearing relative to a given load is smaller with a roller bearing.

■Size and number of rolling elements

The size and number of rolling elements of a bearing are determined based on the targeted performance of the bearing.

Larger rolling elements lead to a greater bearing rigidity. However, a bearing having larger rolling elements tends to be affected by gyratory sliding centrifugal force, and, as a result, its high-speed performance will be degraded. Incidentally, a greater number of rolling elements helps increase bearing rigidity, but at the same time creates an increased number of heat generation sources, possibly leading to greater temperature rise.

For this reason, smaller size of rolling elements are used for high-speed applications.

To achieve both "high speed" and "high rigidity", each type of the **NTN** angular contact ball bearing for a machine tool is manufactured according to optimized specifications for interior structure.

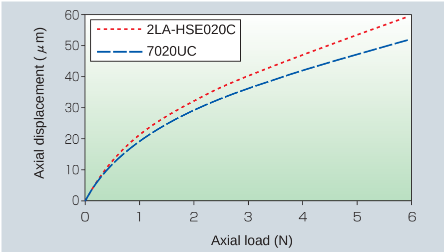


Fig. 2.5

■Material of rolling element (ceramic and steel)

Certain **NTN** bearings incorporate ceramic rolling elements. As Young's modulus of silicon nitride (315 GPa) is greater than that of bearing steel (210 GPa), the rigidity with this type of bearing is accordingly greater.

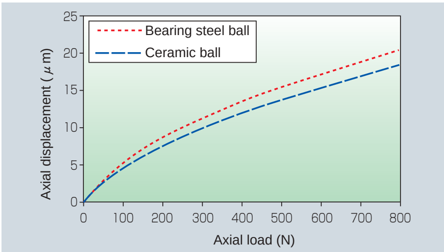

Fig. 2.6

■Bearing contact angle

A smaller contact angle on an angular contact ball bearing results in greater radial rigidity. When used as a thrust bearing, this type of bearing should have a greater contact angle to enable greater axial rigidity.

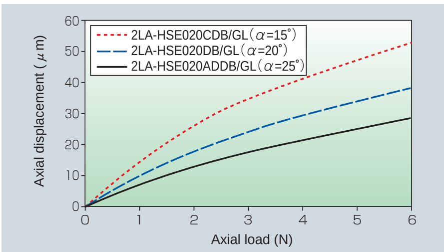

Fig. 2.7

■Preload on bearing

A greater preload on a given bearing results in greater rigidity (**Fig. 2.8**). However, too great of a preload on a bearing can lead to overheating, seizure, and/or premature wear of the bearing. It is possible to use bearings in three- or four-row configurations in order to achieve increased axial rigidity (**Fig. 2.9**).

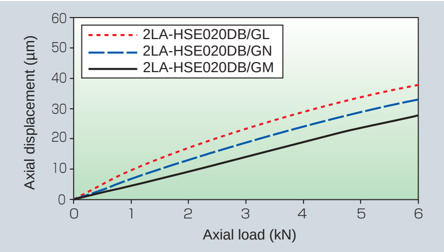

Fig. 2.8

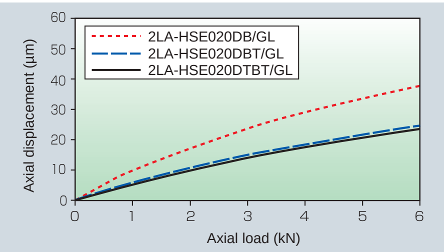

Fig. 2.9

■Preloading technique and preload

Bearing preloading techniques can be categorized as definite position preloading and constant pressure preloading (**Fig. 2.10**).

Definite position preloading is useful in enhancing the rigidity of a bearing unit, as the positional relationship across individual bearings can be maintained. On the other hand, as preloading is achieved with spring force, the constant pressure preloading technique can maintain a preload constant even when the bearing-to-bearing distance varies due to heat generation on the spindle or a change in load.

The basic preload for a duplex bearing is given in the relevant section for each bearing.

If an angular contact ball bearing is to be used for a high-speed application, such as for the main spindle of a machine tool, determine the optimal preload by considering the increase in contact surface pressure between rolling elements and the raceway surface that results from gyratory sliding and centrifugal force. When considering such an application, consult **NTN** Engineering.

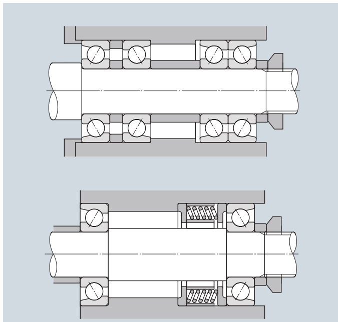

Fig. 2.10

■Preload and rigidity

The effect of preloading for an increase in bearing rigidity is summarized in **Fig. 2.11**.

When the inner rings in the diagram are tightened to bring them together, bearings Ⅰ and Ⅱ are each axially displaced by dimension δ_o, thereby attaining a preload F_o. In this situation, if an axial load F_a is further exerted from outside, the displacement on bearing Ⅰ increases by δ_a, while the displacement on bearing Ⅱ decreases.

At this point, the loads on bearings Ⅰ and Ⅱ are F_{I} and F_{II}, respectively. When compared with δ_b (the displacement occurring when an axial load F_a is exerted onto a non-preloaded bearing Ⅰ), displacement δ_a is small. Thus, a preloaded bearing has higher rigidity.

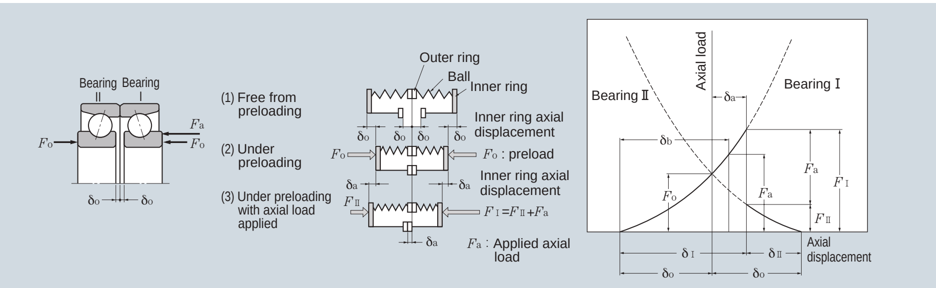

Fig. 2.11 Preload graph

■ Gyratory sliding

Every rolling element (ball) in an angular contact ball bearing revolves on the axis of rotation A-A' as illustrated in **Fig. 2.12**. A revolving object tends to force the axis of rotation to a vertical or horizontal attitude. As a result, the rolling element develops a force to alter the orientation of the axis of rotation. This force is known as a gyratory moment (M).

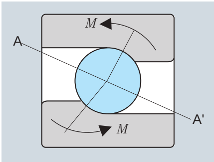

Fig. 2.12 Gyratory sliding

When the force due to the gyratory moment is greater than the resistance force (rolling element load multiplied by the coefficient of friction between the raceway and rolling element) , gyratory sliding occurs on the raceway surface. This leads to heat generation, wear and seizure. Therefore, it is necessary to provide a sufficient resistance force to inhibit gyratory sliding. **NTN**'s recommended preload is based on this theory.

The gyratory moment that will occur can be calculated by the formula below.

$$M = k \times \omega_b \times \omega_c \times \sin\beta$$

$$k = \frac{1}{10} \times m \times d_w^2$$

$$= 0.45 \times \rho \times d_w^5$$

$$M \propto d_w^5 \times n^2 \times \sin\beta$$

M : Gyratory moment
ω_b : Autorotation angular velocity of rolling element
ω_c : Angular velocity of revolution
m : Mass of rolling element
ρ : Density of rolling element
d_w : Diameter of rolling element
β : Angle of axis of rotation of rolling element
n : Speed of inner ring

■ Spin sliding

Every rolling element (ball) in an angular contact ball bearing develops spin sliding that is unavoidable owing to the structure of the bearing, relative to the raceway surface of either the inner ring or outer ring (**Fig. 2.13**).

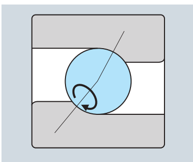

Fig. 2.13 Spin sliding

Usually, at a lower speed range, pure rolling motion occurs between an inner ring raceway and rolling elements and spin sliding develops between an outer ring raceway and rolling elements (this state is known as inner ring control). At a higher speed range, pure rolling motion occurs between an outer ring raceway and rolling elements and spin sliding develops between an inner ring raceway and rolling elements (this state is known as outer ring control). A point where transfer from inner ring control to outer ring control occurs is known as control transfer point. An amount of spin sliding and control transfer point can vary depending on the bearing type and bearing data. Generally, the amount of spin sliding will be greater with an outer ring control state.

According to J. H. Rumbarger and J. D. Dunfee, when the amount of spin sliding exceeds 4.20×10^6 (N/m m^2-mm/s), increase of heat generation and wear start.

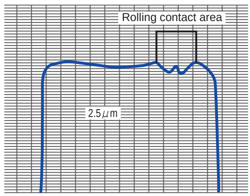
Generally, it is necessary for a bearing of a high-speed main spindle to have a preload that can prevent spin sliding.

The example of wear on a bearing owing to spin sliding is given in **Fig. 2.14**.

The magnitude of spin-derived wear is governed by a PV value (amount of spin sliding) during operation of the main spindle. Therefore, the optimum bearing for main spindle must be selected. Though the possibility of spin-derived wear occurrence varies depending on the bearing type, model number and specifications, we carefully determined a control transfer point in an operating arrangement for **NTN** angular contract ball bearings for main spindles of machine tools. Thus, we believe that the amount of spin sliding with this bearing category is not very large.

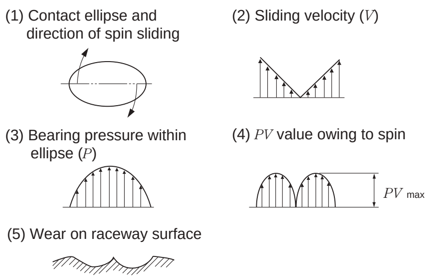
Additionally, the magnitude of spin-derived wear is significantly affected by how well the raceway surface is lubricated. Regardless of the type of sliding, even minor sliding can lead to wear if oil film is not formed well. For this reason, a reliable lubrication arrangement needs to be incorporated.

The form of wear on the bearing raceway derived from spin sliding appears as  . The wear on the raceway surface on inner ring that resulted from spin sliding is given below.



Bearing: 7026T1
Thrust load: 2 kN
Speed: 5000 min^{-1}
Lubrication: Grease
Run time: 50 h

Possible causes for  type wear



2.14 Mechanism of wear on bearing owing to spin sliding

④ Designing shaft and housing

In designing a bearing and housing, it is very important to provide a sufficient shoulder height for the bearing and housing so as to maintain bearing and housing accuracies and to avoid interference with the bearing related corner radius.

The chamfer dimensions are shown in **Table 2.10** and the recommended shoulder height and corner radii on the shaft and housing are listed in **Table 2.11**.

■Bearing corner radius dimensions

15	21
19	25

❹ These are the allowable minimum dimensions of the chamfer dimension "r" or "r_1" and are described in the dimensional table.

■Abutment height and fillet radius

The shaft and housing abutment height (h) should be larger than the bearing's maximum allowable chamfer dimensions ($r_{s\ max}$), and the abutment should be designed so that it directly contacts the flat part of the bearing end face. The fillet radius (r_a) must be smaller than the bearing's minimum allowable chamfer dimension ($r_{s\ min}$) so that it does not interfere with bearing seating. **Table 2.11** lists abutment height (h) and fillet radius (r_a).

For bearings that support very large axial loads, shaft abutments (h) should be higher than the values in the table.

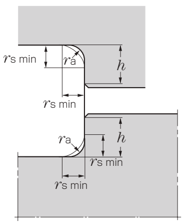

Table 2.11 Fillet radius and abutment height

Unit mm

Chamfer length $r_{s\ min}$ or $r_{s1\ min}$	Fillet radius (radius) $r_{as\ max}$	Shoulder height h (min) Normal use❶

3. Load Rating and Life

① Bearing life

Even in bearings operating under normal conditions, the surfaces of the raceway and rolling elements are constantly being subjected to repeated compressive stresses which causes flaking of these surfaces to occur. This flaking is due to material fatigue and will eventually cause the bearings to fail. The effective life of a bearing is usually defined in terms of the total number of revolutions a bearing can undergo before flaking of either the raceway surface or the rolling element surfaces occurs.

Other causes of bearing failure are often attributed to problems such as seizure, abrasions, cracking, chipping, scuffing, rust, etc. However, these so called "causes" of bearing failure are usually caused by improper installation, insufficient or improper lubrication, faulty sealing or improper bearing selection. Since the above mentioned "causes" of bearing failure can be avoided by taking the proper precautions, and are not simply caused by material fatigue, they are considered separately from the flaking aspect.

Usually, the load exerted on the main spindle of a machine tool is relatively small compared to the dynamic rated load on the bearing. Therefore, the fatigue life of a bearing seldom poses a problem.

The following operating conditions, rather than a bearing's rating life, can significantly affect the bearing functions (running accuracy, rigidity, heat generation, etc.) and require special consideration.

(1) High speed operation.
(2) Heavy preload.
(3) Large bending of the shaft.
(4) Large temperature difference between the inner and outer rings.

For further information, please consult **NTN** Engineering.

■Basic rating life and basic dynamic load rating

A group of seemingly identical bearings when subjected to identical load and operating conditions will exhibit a wide diversity in their durability.

This "life" disparity can be accounted for by the difference in the fatigue of the bearing material itself. This disparity is considered statistically when calculating bearing life, and the basic rating life is defined as follows.

The basic rating life is based on a 90% statistical model which is expressed as the total number of revolutions 90% of the bearings in an identical group of bearings subjected to identical operating conditions will attain or surpass before flaking due to material fatigue occurs. For bearings operating at fixed constant speeds, the basic rating life (90% reliability) is expressed in the total number of hours of operation.

Basic dynamic load rating expresses a rolling bearing's capacity to support a dynamic load. The basic dynamic load rating is the load under which the basic rating life of the bearing is 1 million revolutions. This is expressed as pure radial load for radial bearings and pure axial load for thrust bearings. These are referred to as "basic dynamic load rating (C_r)" and "basic dynamic axial load rating (C_a)." The basic dynamic load ratings given in the bearing tables of this catalog are for bearings constructed of **NTN** standard bearing materials, using standard manufacturing techniques.

The relationship between the basic rating life, the basic dynamic load rating and the bearing load is given in the formula below.

For ball bearings: $$L_{10} = \left(\frac{C}{P}\right)^3 \quad \cdots\cdots (3.1)$$

$$L_{10h} = \frac{10^6}{60n}\left(\frac{C}{P}\right)^3 \quad \cdots\cdots (3.2)$$

For roller bearings: $$L_{10} = \left(\frac{C}{P}\right)^{10/3} \quad \cdots\cdots (3.3)$$

$$L_{10h} = \frac{10^6}{60n}\left(\frac{C}{P}\right)^{10/3} \quad \cdots\cdots (3.4)$$

where,

L_{10} : Basic rating life, 10^6 revolutions
L_{10h} : Basic rating life, h
C : Basic dynamic load rating, N {kgf}
(C_r: radial bearings, C_a: thrust bearings)
P : Equivalent dynamic load, N {kgf}
(P_r: radial bearings, P_a: thrust bearings)
n : Rotational speed, min^{-1}

When several bearings are incorporated in machines or equipment as complete units, all the bearings in the unit are considered as a whole when computing bearing life (see formula 3.5).

$$L = \frac{1}{\left(\frac{1}{L_1^e} + \frac{1}{L_2^e} + \cdots \frac{1}{L_n^e}\right)^{1/e}} \quad \cdots\cdots (3.5)$$

where,

L : Total basic rating life of entire unit, h
L_1 , L_2 ⋯L_n: Basic rating life of individual bearings, 1, 2, ⋯n, h
e = 10/9..........For ball bearings
e = 9/8............For roller bearings

When the load conditions vary at regular intervals, the life can be given by formula (3.6).

$$L_m = \left(\frac{\Phi_1}{L_1} + \frac{\Phi_2}{L_2} + \cdots \frac{\Phi_j}{L_j}\right)^{-1} \cdots\cdots (3.6)$$

where,

L_m : Total life of bearing

Φ_j : Frequency of individual load conditions ($\Sigma\Phi_j = 1$)

L_j : Life under individual conditions

■Adjusted rating life

The basic bearing rating life (90% reliability factor) can be calculated by the formula (3.2) mentioned. However, in some applications a bearing life factor of over 90% reliability may be required. To meet these requirements, bearing life can be lengthened by the use of specially improved bearing materials or manufacturing process. Bearing life is also sometimes affected by operating conditions such as lubrication, temperature and rotational speed.

Basic rating life adjusted to compensate for this is called "adjusted rating life," and is determined by using the formula (3.7).

$$L_{na} = a_1 \cdot a_2 \cdot a_3 \cdot L_{10} \cdots\cdots\cdots (3.7)$$

where,

L_{na} : Adjusted rating life in millions of revolutions (10^6)

a_1 : Reliability factor

a_2 : Bearing characteristics factor

a_3 : Operating conditions factor

●Life adjustment factor for reliability a_1

The value of reliability factor a_1 is provided in **Table 3.1** for reliability of 90% or greater.

Table 3.1 Reliability factor a_1

Reliability %	L_n	Reliability factor a_1
90	L_{10}	1.00
95	L_5	0.62
96	L_4	0.53
97	L_3	0.44
98	L_2	0.33
99	L_1	0.21

●Life adjustment factor for material a_2

Bearing characteristics concerning life vary according to bearing material, quality of material and use of special manufacturing processes. In this case, life is adjusted by the bearing characteristics factor a_2.

The basic dynamic load ratings listed in the catalog are based on **NTN**'s standard material and process, therefore, the adjustment factor $a_2 = 1$. $a_2 > 1$ may be used for specially enhanced materials and manufacturing methods. If this applies, consult **NTN** Engineering.

●Life adjustment factor for operating conditions a_3

Operating conditions factor a_3 is used to compensate for when the lubrication condition worsens due to rise in temperature or rotational speed, lubricant deteriorates, or becomes contaminated with foreign matters.

Generally speaking, when lubricating conditions are satisfactory, the a_3 factor has a value of one. And when lubricating conditions are exceptionally favorable and all other operating conditions are normal, a_3 can have a value greater than one. a_3 is however less than 1 in the following cases:

- Dynamic viscosity of lubricating oil is too low for bearing operating temperature (13 mm^2/s or less for ball bearings, 20 mm^2/s for roller bearings)
- Rotational speed is particularly low (If multiplication of rotational speed n min^{-1} and pitch circle diameter across rolling elements d_m mm is $d_m n < 10{,}000$)
- Bearing operating temperature is too high
- Lubricant is contaminated with foreign matter or moisture

■New bearing life formula

By dramatic improvement in bearing materials and bearing manufacturing techniques, bearings can offer a life several times as long as that calculated from the formula (3.7) as long as they are mounted with minimal mounting errors are fully free from foreign matter and adequately lubricated. This finding was obtained by a series of experiments performed by **NTN**. **NTN**'s new bearing life calculation theory is based on a fatigue limit theory according to which under clean and efficient lubrication conditions, bearing life can be indefinite at a particular contact surface pressure. For this purpose, **NTN** performs calculations based on the contact surface pressure at a fatigue limit of 1.5 GPa that is defined in ISO281: 1990/Amd2: 2000. Incidentally, if foreign matter enters into a bearing, depending on the size and amount of foreign matter, the actual life of that bearing can be much shorter than the rating life that is calculated by formula (3.7). Also, poor lubricating conditions can cause the actual bearing life to be shorter than the rating life. **NTN**'s new bearing life calculation is designed to determine a new life correction factor a_{NTN} by the following formula.

$$L_{nm} = a_1 \cdot a_{NTN} \cdot \left(\frac{C}{P}\right)^p \quad \cdots\cdots (3.8)$$

■Bearing life theory

(1) Conventional Lundberg-Palmgren (L-P) theory

According to this theory, a stress that governs rolling fatigue is considered, that is, a maximum dynamic shear stress τ_o that is exerted, at a depth of Z_o from the rolling contact surface, in a plane parallel with the rolling contact surface. Referring to a theory of Neuber, et. al. which claims that the durability of a material deteriorates as the volume being subjected to a stress application decreases, the L-P theory assumes that a fissure occurring at a weak point of material at around the depth Z_o reaches the surface and leads to develop flaking. The probability of survival S of a volume V that is subjected to N times of stress application is determined by the formula below according to the Weibull theory.

$$\ln \frac{1}{S} \propto \frac{N^e \tau_0^c V}{z_0^h} \quad \cdots\cdots (3.9)$$

where,

- S : Probability of survival of stress volume V
- N : Number of repeated stress applications
- e : Weibull slope (index to represent variation in life)
- τ_o : Maximum shear stress
- Z_o : Depth from surface at which maximum shear stress occurs
- c, h : Indexes

From the basic formula for the bearing life relative to rolling fatigue (3.9), a generic life formula below is obtained:

$$L_{10} = \left(\frac{C}{P}\right)^p \quad \cdots\cdots (3.10)$$

where,

- L_{10} : Basic rating life
- C : Basic dynamic load rating
- P : Dynamic equivalent load
- p : $(c-h+2)/3e$ (point contact)
  $(c-h+1)/2e$ (line contact)

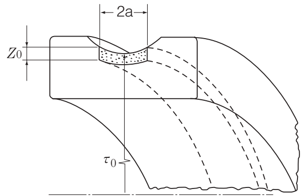

Fig. 3.1 Stress volume resulting from rolling contact according to L-P theory

(2) NTN's new bearing life theory

While the L-P theory intends to define internally occurring flaking owing to the shear stress within a material that results from hertzian contact, **NTN**'s new bearing life theory is designed not only to evaluate surface-initiated flaking but also to determine life of each small segment (ΔL_1) based on a local stress (σ_1). This is done by dividing an area from the interior to the contact surface of the material into small segments as illustrated in **Fig. 3.2**, and finally obtaining the overall bearing life L by the formula (3.13).

$$\ln \frac{1}{\Delta S_i} \propto \frac{\Delta N_i^e \sigma_i^c \Delta V_i}{z_i^h} \quad \cdots\cdots (3.11)$$

$$\Delta L_i = \Delta N_i \propto \left(\sigma_i^{-c} \Delta V_i^{-1} z_i^h\right)^{1/e} \quad \cdots\cdots (3.12)$$

$$L = \left\{\sum_{i=1}^{n} \Delta L_i^{-e}\right\}^{-1/e} \quad \cdots\cdots (3.13)$$

where,

- ΔS_i : probability of survival of stress volume ΔV_i of divided segment
- L : Overall bearing life
- Z_i : Depth of divided small stress volume ΔV_i from the surface
- n : Number of segments
- σ_u : Fatigue limit stress
  - A stress below which a bearing does not develop failure (flaking) under ideal lubrication conditions.
  - ISO 281: 1990/Amd2: 2000 specifies 1.5 GPa as a the maximum contact surface pressure at a fatigue limit. **NTN** uses it as a Von Misses stress equivalent to the maximum contact surface pressure 1.5 GPa.
  - When σ_i is smaller than σ_u (fatigue limit), the life of a region in question (ΔL_1) will be infinitely long.

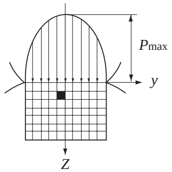

Fig. 3.2 Calculation model

■NTN's new bearing life formula

The correlation between the **NTN**'s life correction factor a_{NTN} and corrected rating life L_{nm} is defined by the formula (3.14) below.

$$L_{nm}=a_1\cdot a_{NTN}\cdot\left(\frac{C}{P}\right)^{p} \quad (3.14)$$

where,

- L_{nm} : Corrected rating life
- a_1 : Reliability coefficient
- a_{NTN} : Life correction factor that reflects material properties, fatigue limit stress, contamination with foreign matter and oil film parameter (Λ) ($0.1 \leqq a_{NTN} \leqq 50$)
- C : Basic dynamic load rating
- P : Dynamic equivalent load
- p : Index 3 (ball bearing) 10/3 (roller bearing)

(1) Effect of fatigue limit

NTN's new bearing life formula introduces a concept of fatigue life according to which the bearing life is infinitely long at a particular contact surface pressure as illustrated in **Fig. 3.3** assuming no foreign matter is trapped in the bearing and the bearing is reliably lubricated.

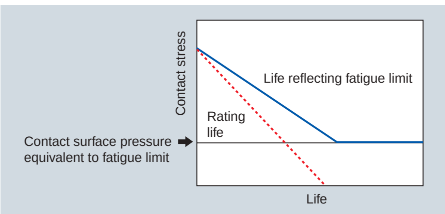

Fig. 3.3 Basic concept of fatigue limit

(2) Effect of foreign matter

The effect of foreign matter is treated as surface-initiated flaking that starts from a dent resulting from trapped foreign matter. **NTN** performs a bearing life calculation, assuming that the size of foreign matter and the stress concentration area in the middle portion (the size of this area corresponds with that of the foreign matter) in the surface layer as well as the amount of foreign matter significantly affect the bearing life.

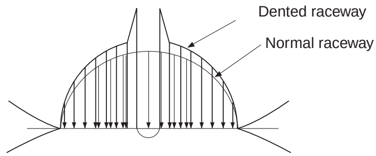

Fig. 3.4 Contact surface pressure distribution resulting from dent

(3) Effect of oil film parameter (Λ)

The oil film parameter can be used to calculate bearing life. The oil film parameter, designated by Λ, is the ratio of the oil film thickness to the roughness of the surface. It can be used to calculate the average stress across the surface layer of two contacting surfaces, such as a rolling element and raceway. From this surface layer stress, the contact surface pressure can be determined. Bearing life is then calculated from the contact surface pressure.

Conditions of two objects on surface layer
Calculation model

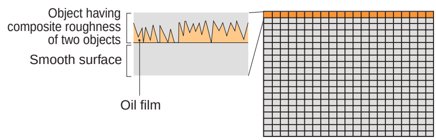

Fig. 3.5 Model of stress load onto the surface layer

■New life calculation formula chart

Various statuses of contamination with foreign matter are defined in **Table 3.2**. The values of ISO codes and NAS classes are those for ball bearings that are subjected to more severe operating conditions.

Table 3.2 Status of contamination

Condition of contamination	Extremely clean	Clean	Normal	Lightly contaminated	Moderately contaminated	Highly contaminated	Severely contaminated
Contamination coefficient	1	0.8	0.5	0.4	0.3	0.2	0.1
Guideline for application	Filtered						No filter
	Less than 10 m	10～30 μm	30～50 μm	50～70 μm	70～100 μm	100 m or more	Ingress of much dust
ISO cleanliness code (ISO 4406)	13/10	15/12	17/14	19/16	21/18	23/20	25/22
NAS class	0	3	6	8	9	10	12

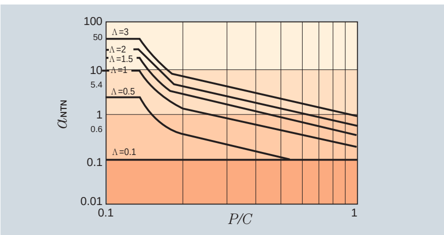

Fig. 3.9 Correlation between P/C and a_{NTN} (effect of Λ with roller bearing)

② Static load rating and allowable axial load

■Basic static load rating

When stationary rolling bearings are subjected to static loads, they suffer from partial permanent deformation of the contact surfaces at the contact point between the rolling elements and the raceway. The amount of deformity increases as the load increases, and if this increase in load exceeds certain limits, the subsequent smooth operation of the bearings is impaired.

It has been found through experience that a permanent deformity of 0.0001 times the diameter of the rolling element, occurring at the most heavily stressed contact point between the raceway and the rolling elements, can be tolerated without any impairment in running efficiency.

The basic static load rating refers to a fixed static load limit at which a specified amount of permanent deformation occurs. It applies to pure radial loads for radial bearings and to pure axial loads for thrust bearings. The maximum applied load values for contact stress occurring at the rolling element and raceway contact points are given below.

For ball bearings	4 200MPa	{428kgf/mm²}
For self-aligning ball bearings	4 600MPa	{469kgf/mm²}
For roller bearings	4 000MPa	{408kgf/mm²}

Referred to as "basic static radial load rating" for radial bearings and "basic static axial load rating" for thrust bearings, basic static load rating is expressed as C_{or} or C_{oa} respectively and is provided in the bearing dimensions table.

■Allowable static equivalent load

Generally the static equivalent load which can be permitted is limited by the basic static rating load as stated above. However, depending on requirements regarding friction and smooth operation, these limits may be greater or lesser than the basic static rating load.

This is generally determined by taking the safety factor S_o given in **Table 3.3** and formula (3.13) into account.

$$S_o = C_o / P_o \qquad (3.13)$$

where,

S_o : Safety factor
C_o : Basic static load rating, N {kgf}
radial bearings: C_{or},
thrust bearings: C_{oa}
P_o : Static equivalent load, N {kgf}
radial bearings: P_{or},
thrust bearings: P_{oa}

Table 3.3 Minimum safety factor values S_0

Operating conditions	Ball bearings	Roller bearings
High rotational accuracy necessary	2	3
Normal rotating accuracy necessary (Universal application)	1	1.5
Slight rotational accuracy deterioration permitted (Low speed, heavy loading, etc.)	0.5	1

Note: When vibration and/or shock loads are present, a load factor based on the shock load needs to be included in the P_0 max value.

■Allowable axial load

A greater axial load can be exerted on a main spindle bearing on a machine tool allowing for tool changes while the machine is stationary. When an angular contact ball bearing is subjected to a larger axial load, the contact ellipse between its rolling elements and raceway surface can overflow the raceway surface (**Fig. 3.10**). Furthermore, even if the contact ellipse remains within the raceway surface, overstressing can cause problems such as denting.

The maximum allowable load that does not cause such problems is defined as the "allowable axial load."

The allowable axial load is reached when either of the following conditions occurs.

- **The end of contact ellipse on the raceway surface reaches the shoulder of either an inner or outer ring.**
- **The contact surface pressure on the raceway surface reaches 3650 MPa in either the inner or outer ring raceway.**

Note that the contact surface pressure of 3650 MPa on the raceway surface is a value that leads to a permanent deformation of 0.00002 to 0.00005 times as much as the rolling element diameter and has been determined through many years of experience.

The allowable axial load for each bearing is found in the associated dimensions table.

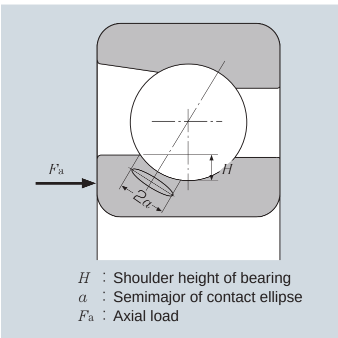

Fig. 3.10

4. Allowable Speed

High bearing speed leads to high temperature rise on the bearing owing to frictional heating within the bearing. When the temperature of the bearing exceeds a particular limit, the lubricant performance deteriorates significantly, possibly leading to bearing overheating or seizure.

The factors that can affect the maximum allowable bearing speed include:

(1) Bearing type
(2) Bearing size
(3) Lubrication system (grease lubrication, air-oil lubrication, jet lubrication, etc.)
(4) Internal clearance or preload on the bearing
(5) Bearing arrangement (2-row, 3-row, 4-row)
(6) Bearing load
(7) Accuracies of shaft, housing, etc.

The maximum allowable speeds listed in the bearing dimensions tables are reference values and are applicable only to individual bearings that are adequately lubricated and correctly preloaded under a condition where the heat is reliably removed from the bearing arrangement.

In the case of grease lubrication, these speeds are attainable only when the bearing is filled with an adequate amount of high-quality grease as given in **Table 7.3**, the bearing is sufficiently run in, and heat is removed by an arrangement such as a cooling jacket. In the case of oil lubrication, these speeds are attained only by an air-oil lubrication system if an adequate amount of VG10 or 32 spindle oil is supplied and the heat is removed by an arrangement such as a cooling jacket. When using a large amount of lubricant, a jet lubrication system excels in lubrication and cooling performance, and can permit operation at the maximum allowable speed. However, this lubrication system involves a high power loss and should be employed carefully.

■Speed factor

The maximum allowable speed of a particular bearing can vary depending on the relation between heat generation and heat dissipation in the bearing as well as how well the bearing is lubricated. The bearing arrangements (2-row to 4-row) and speed reduction ratios (speed factors) for maximum allowable speed due to post-assembly preloads are summarized in **Table 4.1**.

Table 4.1 Speed factor by bearing arrangement and preload

Bearing arrangement	Matching	GL	GN	GM
	DB	0.85	0.8	0.65
	DBT	0.7	0.6	0.5
	DTBT	0.8	0.75	0.6

5. Bearing Arrangements and Structures of Bearings for Main Spindles

① Bearing Arrangement for Main Spindles

Typical examples of bearing arrangements for main spindles of machine tools are summarized in **Table 5.1**.

An optimal bearing arrangement must be determined through considerations about the properties required of the main spindle in question (maximum speed, radial and axial rigidities, main spindle size, required accuracies, lubrication system, etc.). Recently, an increasing number of new machine tool models incorporate built-in motor type main spindles. However, heat generation on a built-in motor can affect the accuracy of the main spindle and performance of lubricant, so a main spindle bearing should be selected very carefully.

Table 5.1 Typical examples of bearing arrangements for main spindles

Bearing arrangement for main spindle	Bearing type	Typical applications
 Gear-driven configuration	[Type Ⅰ] Tapered roller bearing + Tapered roller bearing + Double-row cylindrical roller bearing	Large turning machine Oil country lathe General-purpose turning machine Typical lubrication ● Grease lubrication

② Bearing selection based on bearing arrangement for main spindle

An optimal bearing product that best suits the application is selected by referring to the bearing selection table in **Table 5.2**, which contains the possible bearing arrangements for main spindles.

- Designate the free side and fixed side.
- Select the bearing arrangement type (I to XII) on the free or fixed side.
- Select a set of bearing specifications applicable to the selected arrangement type.
- Choose a lubrication system suitable for the selected bearing specifications.
- Select a product group that satisfies the above-mentioned considerations.

Table 5 2 Bearing selection table

Fix side	Free side	Bearing specifications	Lubrication system		Applicable product groups/ULTAGE Steel balls/ceramic balls	Considerations for selection procedure
Duplex angular contact ball bearing or adjustable preload bearing mechanism + Duplex angular contact ball bearing Bearing arrangement [Type IV, VI, VII, IX, XI, or XII]	Single-row angular contact ball bearing or duplex angular contact ball bearing (w/ ball bush) Bearing arrangement [Type VII, VIII, XI, or XII]	Angular contact ball bearing for radial load Contact angle 30° or smaller		Grease lubrication	Sealed: 【15°, 25°】 79 LLB/5S-79 LLB 70 LLB/5S-70 LLB 【15°, 20°, 25°】 2LA-BNS9 LLB/5S-2LA-BNS9 LLB 2LA-BNS0 LLB/5S-2LA-BNS0 LLB	Bearing selection ① High-speed performance (general) High ⇔ Low Contact angle 15°, 20°, 25°, 30° ② Rigidity · Radial rigidity High ⇔ Low Contact angle 15°, 20°, 25°, 30° · Axial rigidity Low ⇔ High Contact angle 15°, 20°, 25°, 30°, 40°, 60° · Complex rigidity (radial and axial) High (4-row) Medium (3-row) Low (2-row) ③ Recommended arrangement 4-row (DTBT) or 2-row (DB) ④ Recommended lubrication specifications Standard main spindle : Grease High-speed main spindle : Air-oil Low-noise : Grease or eco-friendly air-oil ⑤ Presence of cooling jacket around the bearing. ③ Adjustable preload bearing unit

A recent trend in the machine tool industry is a steady increase of operating speeds. The maximum d_mn value (pitch circle diameter across rolling elements d_m [mm] multiplied by speed n [min^{-1}]) reached by main spindles with air-oil lubricated lubrication can be as high as 2.5 to 3.8 $\times 10^6$. At the same time, main spindles are requiring increased rigidity. Therefore, main spindle bearings must be capable of both high-speed operation and high rigidity. This can be achieved through optimal preloading.

A fixed preload (spring preload) system is usually employed to satisfy both these high speed and high rigidity requirements. A spindle unit with fixed-position preload that is adjustable for different speed conditions is advantageous for optimizing the rigidity of the unit.

The **NTN** Adjustable Preload Bearing Unit is a high-speed, high-rigidity unit that features fixed position preload that can be adjusted for different speed conditions.

The **NTN** Adjustable Preload Bearing Unit is illustrated in **Fig. 5.1**. Hydraulic pressure is used to shift the position of the adjustable preload sleeve situated in the rear bearing section of the unit. This changes the preload on the bearings.

A spindle incorporating a 3-step adjustable preload bearing unit is illustrated in **Fig. 5.2**. The sleeve in the adjustable preload section is comprised of two hydraulic pressure chambers, A and B, as well as a spiral groove for sliding motion. The preload can be adjusted to one of three settings by changing the hydraulic pressure in each of the chambers. To achieve instantaneous and reliable adjustment, high-pressure oil (at the same pressure as in the hydraulic chambers) is supplied to the spiral groove on the outside of the sleeve. This oil provides lubrication so that the sleeve can move smoothly.

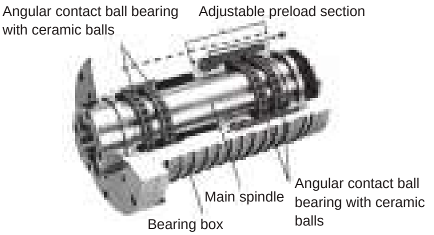

Fig. 5.1 Adjustable preload bearing unit

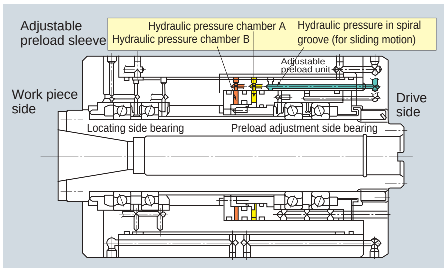

Fig. 5.2 Typical spindle configuration incorporating 3-step Adjustable Preload Type Bearing Unit

■ Operating mechanism

Fig. 5.3 shows the hydraulic operation of the unit for three preloading conditions as well as the associated motion of the adjustable preload sleeve.

- **Low speed operation(high preload): Chamber A is pressurized.**
  Component ① moves to the right by a preset clearance L_1 and contacts component ③. The axial clearance is δ_1.
- **Medium speed operation(medium preload):Chamber B is pressurized**.
- Components ① and ② move to the right by a preset clearance L_2, causing Component ② to contact Component ④. The axial clearance is δ_2.
- **High speed operation(low preload):Chambers A and B are not pressurized.**
  Components ① and ② return to the left due to the reaction force on the bearing. This causes Component ② to contact Component ⑤, thereby returning the axial clearance to the initial setting of δ_3.

NOTE: The return motion of the components ① and ② is achieved by the reaction force of bearing or a separately provided spring.

④ Bearing jacket cooling system

With a built-in motor drive system, the main spindle is directly driven by a motor and is therefore suitable for rapid acceleration or deceleration. However, this system can be adversely affected by temperature rise. A cooling jacket with a spiral groove around the housing allows cooling oil to flow through the unit.

If heat generated by the motor affects the bearing, overheating of the bearing as well as degradation of the grease can occur. This situation must be strictly avoided. When designing a cooling system with jacket cooling, the following should be considered.

■Considerations about cooling of jacket

A typical bearing arrangement is shown in **Fig. 5.4** and **5.5**, comprising a double-row cylindrical roller bearing and an angular contact ball bearing set. The cooling groove on the jacket in **Fig. 5.4** starts at around an area above the angular contact ball bearings and does not cool the double-row cylindrical roller bearing effectively.

(Note that the fit of the angular contact ball bearings with the bore of the housing is a clearance fit-the bearings are not in direct contact with the housing) In the configuration in **Fig. 5.5**, the cooling groove extends to the region above the double-row cylindrical roller bearing, and cools both the angular contact ball bearings and the double-row cylindrical roller bearing effectively.

6. Handling of Bearings

① Cleaning and filling with grease

To achieve maximum speed and limited temperature rise with a precision rolling bearing, it is vital to handle the bearing correctly.

The handling of bearings involves cleaning, drying, filling with grease (if necessary), and the running-in operation. For each step, follow the precautions and instructions.

A sealed bearing contains prefilled grease. Do not clean (rinse) and dry this type of bearing. Only wipe away rust-preventive oil with a clean cloth before assembling the bearing.

■Cleaning (removal of rust-preventive oil)

- Immerse the bearing in kerosene or a highly volatile solvent such as naphthesol and wash it by hand. Then remove the kerosene using benzene or alcohol. Use clean compressed air to blow away the rinsing fluid.
  (The bearing may be used as delivered for the air-oil lubrication. However, we recommend that after cleaning, the bearing either be coated with the lubricant to be used or a less viscous oil, or be immersed in the lubricant or other low-viscosity oil.)

■Drying

If the bearing is to be used with grease lubrication, it is necessary to thoroughly dry the bearing to avoid leakage of grease. After drying, be sure to immediately fill the bearing with grease.

Drying can be performed by blowing hot air onto the bearing or placing the bearing in a chamber at constant temperature. When drying by hot air, be sure to consider the cleanliness of the air.

■Filling with grease

The procedures for greasing ball and roller bearings can be found below.

After filling with grease, turn the bearing by hand to uniformly distribute the grease to the whole rolling surface.

<Ball bearings> See Photo 6.1

- By using an injector or small plastic bag, fill grease between balls in equal amounts, aiming at the inner ring rolling surface.
- For a bearing with a ring-guided cage, also apply grease to the guide surface of the cage using a spatula or similar tool.
- If grease cannot be filled into the inner ring rolling surface because of a small gap between the cage and the inner ring add grease to the outer ring rolling surface. In this case, carefully turn the bearing so that the grease is fully spread on the inner ring side.

<Roller bearings> See Photo 6.2

- Apply grease to the outer (inner) side of rollers, and while turning the rollers with fingers, spread the grease to the inner ring (outer ring) side.

By using an injector or small plastic bag, fill grease between balls in equal amounts, aiming at the rolling surface of the inner ring.

After completion of filling

Turn the bearing by hand while applying an appropriate load in the contact angle direction so that the any area in the interior of bearing is sufficiently lubricated with grease.

Photo. 6.1 Filling grease into angular contact ball bearing

Apply grease to the outer circumference of cage.

Apply grease to the outer side of the rollers, and while turning the rollers with fingers, spread the grease to the inner ring (outer ring) side.

(After applying grease)
If a lump of grease remains on the outer face of cage rib, the running-in operation can take a longer time. With fingers, spread the grease deposited on the outer surface of the rib on the cage.

Photo. 6.2 Filling grease into cylindrical roller bearing

■Running-in operation

(1) Air-oil or oil-mist lubrication

The running-in operation is relatively simple with oil lubrication because no peak temperature occurs and the bearing temperature stabilizes within a relatively short time. **NTN** recommends that the speed of bearing is to be increased in steps of 2000 to 3000 min^{-1} until the maximum speed is reached.

Every speed setting should be maintained for about 30 minutes. However, for the speed range where the $d_m n$ (pitch circle diameter across rolling elements multiplied by speed) exceeds 1.0×10^6, increase the bearing speed in steps of 1000 to 2000 min^{-1} to ensure the stable running.

(2) Grease lubrication

For a grease-lubricated bearing, a running-in operation is very important in attaining stable temperature rise. During a running-in operation, a large temperature rise (peak) occurs while the bearing speed is increased, and then the bearing temperature eventually stabilizes. Before temperature stabilization, a certain lead time will be needed.

Ball bearing

NTN recommends that the bearing speed be increased in steps of 1000 to 2000 min^{-1} and be further increased only after the temperature has stabilized at the current speed setting.

However, for the speed range where the $d_m n$ exceeds 0.4×10^6, increase the bearing speed in steps of 500 to 1000 min^{-1} to ensure the stable running.

Roller bearing

Compared with contact ball bearings, the time to peak temperature or saturation in running-in operation of roller bearings tends to be longer. Also, there will be temperature rise due to whipping of the grease and the temperature rise may be unstable. To cope with this problem, run the roller bearing in the maximum speed range for a prolonged period.

Increase the bearing speed in steps of 500 to 1000 min^{-1} only after the bearing temperature has stabilized at the current speed setting.

For the speed range where the $d_m n$ exceeds 0.3×10^6, increase the bearing speed in steps of 500 min^{-1} to ensure safety.

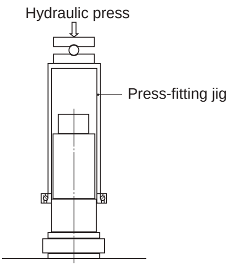

Fig. 6.1 Press-fitting pressure

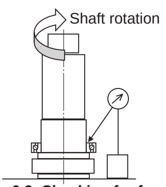

Fig. 6.2 Checking for face runout of inner ring

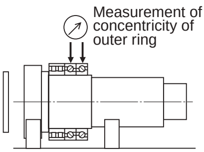

Fig. 6.3 Checking for concentricity of outer ring

② Mounting

When mounting a bearing to a main spindle, follow either of the mounting techniques described below

(1) Press-fitting with hydraulic press

(2) Mounting by heating bearings

With either technique, it is important to minimize the adverse effects of the mounting process to maintain bearing accuracy.

(1) Press-fitting with hydraulic press

Before press-fitting a bearing with a hydraulic press or hand press, the press-fitting force due to the interference between the shaft and inner ring must be calculated. A hydraulic press having a capacity greater than the required press-fitting force must used. Next, using an inner ring press-fitting jig, the inner ring is correctly press-fitted to the shoulder of shaft. Please be careful not to exert a force on the outer ring.

After the press-fitting operation, it is important to measure the accuracies of various portions of the bearing to verify that the bearing has been correctly mounted to the shaft. When using a multi row bearings, measure the runout after assembly and correct misalignment across the outer rings as necessary.

■Calculation of press-fitting force

The press-fitting force occurring from the interference between the shaft and inner ring can be determined by the formula given below.

According to the calculated press-fitting force, a hydraulic press having a sufficiently large capacity must be used to mount the bearing. The variations in dimensional errors among the bearings should be considered. The force needed to press the inner ring to the shaft can be obtained with the following formula (6.1).

Force to press-fit inner ring to shaft

$$K_d = \mu \cdot P \cdot \pi \cdot d \cdot B \quad \cdots\cdots (6.1)$$

where,

K_d: Force for press-fitting or extracting an inner ring N
P : Surface pressure on fitting surface MPa (see **Table 6.1**)
d : Shaft diameter, inner ring bore diameter mm
D : Outer ring outside diameter mm
B : Inner ring width
μ : Sliding friction coefficient (when press-fitting inner ring over cylindrical shaft: 0.12)

Table 6.1

	Fitting conditions and calculation formulas	Symbol (unit N [kgf]-mm)
Fitting surface pressure MPa [kgf/mm²]	Fits between solid steel shaft and inner ring $P=\frac{E}{2}\frac{\Delta deff}{d}\left[1-\left(\frac{d}{D_i}\right)^2\right]$ ·············· (6.2)	d : Shaft diameter, inner ring bore diameter do : Hollow shaft bore diameter D_i :Inner ring average raceway groove diameter
	Fits between hollow steel shaft and inner ring $P=\frac{E}{2}\frac{\Delta deff}{d}\frac{[1-(do/D_i)^2]\,[1-(do/d)^2]}{[1-(do/D_i)^2]}$ ·············· (6.3)	$\Delta deff$: Effective interference E : Modulus of longitudinal elasticity = 210 GPa

$$\Delta deff=\frac{d}{d+2}\Delta d \quad\cdots\cdots\quad (6.4)$$

(In the case of a ground shaft)

Δd : Theoretical interference fitting

$$D_i=1.05\frac{4d+D}{5} \quad\cdots\cdots\quad (6.5)$$

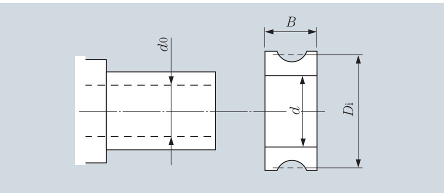

Fig. 6.4

Example of calculation for press-fitting force

The calculation for press-fitting force for tight fit of 2 μm interference between the shaft and inner ring for the standard angular contact ball bearing is as summarized below:

- 7020UC (ϕ100×ϕ150× 24)
- Interference fit of 2μm (solid shaft)

$$\Delta deff=\frac{100}{102}\times 0.002=0.00196$$

$$D_i=1.05\times\frac{4\times 100+150}{5}=115.5$$

$$P=\frac{210000}{2}\times\frac{0.00196}{100}\left[1-\left(\frac{100}{115.5}\right)^2\right]=0.52\ \text{MPa}$$

$$=0.12\times 0.52\times\pi\times 100\times 24=470\ \text{N}$$

To accommodate for variation in the lubrication conditions, incorporate a safety factor of 2 to 3. As a result, the required press-fitting force is:

470×(2 to 3) = 940 to 1410 N

(2) Mounting by heating bearings

When mounting a bearing to a shaft using a constant temperature chamber, bearing heater or the like, follow the instructions below.

Heat the bearing at a temperature that reflects the interference between the shaft and inner ring (see **Fig. 6.5**).

Assuming linear expansion coefficient 12.5×10⁻⁶, heating temperature Δ , inner ring bore diameter ϕd, and interference fit

δ =12.5×10⁻⁶×d×Δ

Ex.) If ϕd = 100 mm, and δ = 0.030 (30 μm, tight fit), then the required heating temperature Δ = 23.8˚C.

Therefore, the bearing should be heated to approximately room temperature + 30˚C. Note that in practice , the lower-temperature shaft will cool the bearing, causing it to shrink. Consequently the bearing may need to be heated by more than 30˚C for assembly.

NOTE

- If a resin material is used for the cage of angular contact ball bearing, do not excessively heat the bearing (approx. 80˚C max.).
- As a result of heating bearings after cooling, the inner ring will axially shrink, and there will be clearance between the bearing side face and shaft shoulder (**Fig. 6.6**). For this reason, keep the bearing and shaft forced together with a press or the like after the unit returns to normal temperature. After cooling, check that the bearing is mounted to the shaft correctly.
- When using a bearing heater, be sure to avoid overheating. To prevent bearing from being magnetized, use equipment that has a demagnetizing feature.

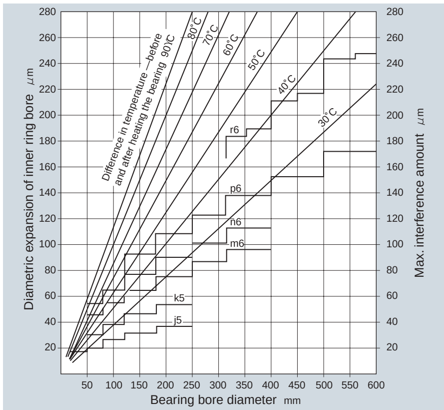

Fig. 6.5 Required heating temperature for mounting by heating inner ring

Remarks: The maximum interference amounts are interference values associated with class 0 bearings.

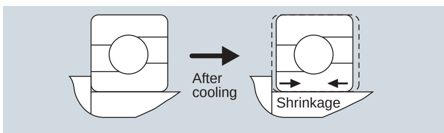

Fig. 6.6 Cooling after mounting by heating bearings

③ Tightening of inner ring

When mounting and securing a bearing to a main spindle, the inner ring side face is usually clamped with a stepped sleeve or precision bearing nut, and the front cover situated on the outer ring side face is bolted down. When utilizing a stepped sleeve or precision bearing nut to clamp the inner ring, the following precautions must be followed.

■Tightening with stepped sleeve

The stepped sleeve is designed that the hydraulically expanded sleeve is inserted over the shaft, and a predetermined drive-up force (tightening force) is applied to the shaft. Then the hydraulic pressure is released in order to secure the sleeve onto shaft and provide a tightening force to the bearing. This technique is a relatively simple locking method (**Fig. 6.7**).

Note however after being locked in position by interference with the shaft, the sleeve can come loose because of deflection of the shaft or a moment load applied to the shaft.

For this reason, in many cases, a stepped sleeve is used together with a bearing nut as illustrated in **Fig. 6.8**.

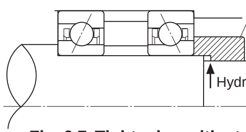

Fig. 6.7 Tightening with stepped sleeve

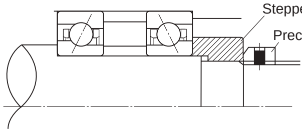

Fig. 6.8 Tightening with stepped sleeve + precision bearing nut

■Tightening with precision bearing nut

Required tightening force is achieved with the precision bearing nut (precision locknut) by correctly controlling the tightening torque.

Note that when a bearing has been locked with a precision bearing nut (lock nut), the nut can develop inclination owing to the clearance on the threaded portions. If this problem occurs, fine adjustment will be necessary to obtain necessary running accuracy for the shaft.

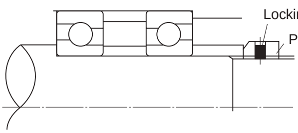

Fig. 6.9 Tightening with precision bearing nut

■Correlation between tightening torque and tightening force with precision bearing nut

The correlation between tightening torque and tightening force with a precision bearing nut can be defined with the formula given below.

Because the thread face of the precision bearing nut, the thread face of the shaft and the bearing surface and nut constitute sliding surfaces, the correlation between tightening torque and tightening force will vary depending on the friction coefficient. Therefore, the nut needs to be thoroughly run on the shaft thread in advance to ensure smooth and uniform tightening.

It is also necessary to determine the correlation between tightening torque and tightening force by using a load washer or the like in advance.

$$F = \frac{M}{(d/2)\tan(\beta+\rho)+r_n\mu_n} \quad \cdots\cdots (6.6)$$

F : Thread tightening force N
M : Nut tightening torque N-mm
d : Effective diameter of thread mm
ρ : Friction angle of thread face

$$\tan\rho = \frac{\mu}{\cos\alpha} \quad \cdots\cdots (6.7)$$

β : Lead angle of thread
$\tan\beta$ = number of threads × pitch/πd ⋯ (6.8)
r_n : Average radius of bearing nut surface mm
μ_n : Friction coefficient of bearing nut surface
$\mu_n \cong 0.15$
μ : Friction coefficient of thread face $\mu \cong 0.15$
α : Half angle of thread

Example calculation

・Bearing nut
AN20 (**Fig. 6.10**)
・Thread data
M100×2 (class 2 thread)
Effective diameter
$d = \phi 98.701$ mm
Half angle of thread $\alpha = 30°$

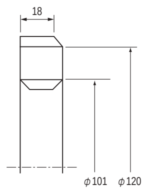

Fig. 6.10

The correlation between a tightening torque and tightening force with the precision bearing nut can be calculated as follows:

$$\tan\rho = \frac{0.15}{\cos 30°} \qquad \rho = 9.826°$$

$$\tan\beta = \frac{1\times 2}{\pi \times 98.701} \qquad \beta = 0.370°$$

$$r_n = \frac{(101+120)/2}{2} = 55.25$$

$$F = \frac{M}{\frac{98.701}{2}\tan(0.370+9.826)+55.25\times 0.15} = \frac{M}{17.163}$$

④ Elastic deformation of spacer by tightening force

When incorporating a bearing into a main spindle, the bearing must be correctly forced into a predetermined position and maintained with a predetermined bearing pressure in order to maintain appropriate accuracies, clearances and rigidities of the bearing and main spindle.

When axially locating a duplex angular contact ball bearing by using a bearing spacer the cross-sectional area of spacer as well as (depending on the tightening force) the bearing pressure and elastic deformation by tightening of the spacer must be considered.

■Correlation between inner ring spacer tightening force and amount of elastic deformation

When securing an angular contact ball bearing onto a main spindle, the bearing inner ring is tightened and locked by the shoulder of main spindle and a bearing nut and/or stepped sleeve. This inner ring tightening force causes the spacer to develop elastic deformation in the axial direction, varying the axial clearance on the bearing. In the case of a back-to-back duplex bearing (DB, DTBT or DBT) for a main spindle in particular, the inner ring tightening force will decrease the bearing clearance, possibly leading to an increased post-assembly preload and operating preload. A possible inner ring tightening force-derived axial deformation can develop in the form of deformation of both the inner ring and inner ring spacer. However, **NTN**'s experience has shown that only the elastic deformation on inner ring spacers needs to be considered.

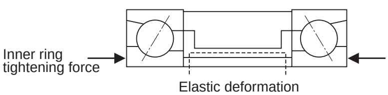

Fig. 6.11 Elastic deformation of inner ring spacer

The amount of deformation of a spacer is calculated using the following formula:

$$\delta = \frac{P \times L}{A \times E} \quad (6.9)$$

δ : Elastic deformation mm
P : Inner ring tightening force N
L : Inner ring spacer width mm
A : Inner ring cross-sectional area mm²
E : Young's modulus 210,000 MPa

The require tightening force exerted onto inner ring spacers varies depending on the bearing manufacturer. From its experience, **NTN** adopts the typical values listed in **Table 6.2**.

Table 6.2 Nut tightening force

Bearing bore diameter (mm)	Nut tightening force (N)	Nut tightening torque <reference value> (N·m)	Front cover drive-up (mm)
6	1470	2	0.01～0.02

220	<reference value> (34300～44100)	—	
240		—	
260		—	
280		—	
300		—	

Note 1) **NTN** has specified the nut tightening forces in this table based on experiences from reviewing and assessing the drawings from users. However, **NTN** has no production record for bore diameter of 220 mm or larger. Thus, the nut tightening forces in parentheses are estimated values.
Note 2) The nut tightening torque is calculated with a friction coefficient of 0.15 between the nut seating face and screw thread surface.
Note 3) When tightening nuts, it is recommended to tighten them to twice the set value, then loosen them, and finally re-tighten them to the recommended set value.
Note 4) For ball screw support bearings (BST), a tightening torque approximately 3 times as large as the preload is recommended.

⑤ Front cover drive-up

When mounting and securing a bearing onto a main spindle, the inner ring is usually tightened with a stepped sleeve or precision bearing nut and the outer ring side is bolted down. When locking the outer ring with a front cover, the following points need to be considered.

■Front cover pressing amount

The bearing outer ring is tightened and locked between the shoulder of the housing and front cover at the main spindle front section. The front cover is installed by utilizing bolt holes (6 to 8 positions) on its flange. The usual pressing allowance on the outer ring and the front cover, which **NTN** has adopted through experience, falls in a range of 0.01 to 0.02 mm. Too large a pressing amount on the outer ring or a smaller number of fastening bolts may lead to poor roundness of the bearing ring.

Typical fit and deterioration in roundness of a raceway surface resulting from a pressing amount of 0.05 mm on the outer ring are shown in **Fig. 6.14**. Also, typical outer ring pressing amount and deterioration of a raceway surface with a fit of 5 μm loose are provided in **Fig. 6.15**.

To avoid deformation of the outer ring raceway surface, **NTN** recommends that the outer ring be installed to a highly accurate housing in transition fit with a large number of bolts.

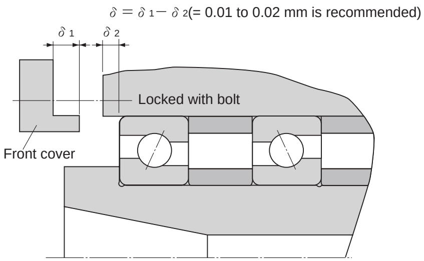

Fig. 6.12 Front cover pressing allowance

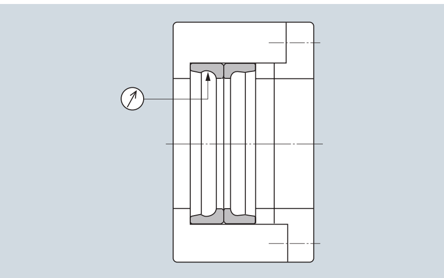

Fig. 6.13 Measuring position for roundness on outer ring raceway surface

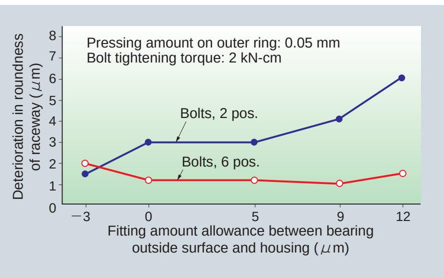

Fig. 6.14 Effect of fit of outer ring on roundness of raceway surface

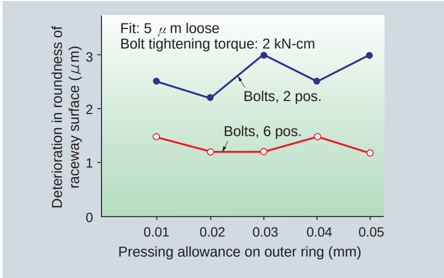

Fig. 6.15 Pressing allowance on outer ring vs. deterioration in roundness of raceway surface

⑥ Checking axial rigidity

In the typical method for checking for the axial rigidity of a bearing installed to a machine tool, the main spindle itself is pushed with a push-pull gage to measure the resultant axial displacement. A method using a dial indicator is described below.

Two dial indicator are placed on two locations (axisymmetric locations separated by 180˚) at the leading end of the main spindle. Use magnetic stands to secure the dial indicator to the end face of housing. Then, apply the load onto the main spindle and the resultant axial displacement is measured.

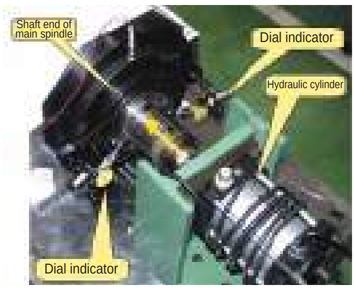

Photo 6.3

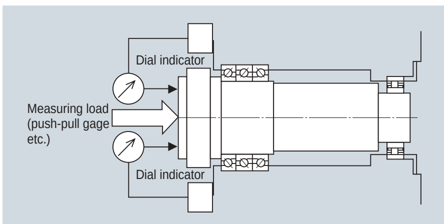

Fig. 6.16 Checking for axial rigidity

⑦ Clearance adjustment for cylindrical roller bearing

When incorporating a cylindrical roller bearing into a main spindle of a machine tool such as an NC turning machine or machining center, and setting the internal clearance to zero or to a negative clearance, the inner ring of the bearing usually has a tapered bore.

The internal clearance is adjusted by fitting the tapered bore bearing onto the tapered portion of the main spindle and driving the bearing in the axial direction to expand the inner ring.

For adjusting the internal clearance, two methods are available: a method consisting of clearance measurement for each bearing and adjustment with a spacer(s), and a method with a post-mounting internal clearance adjustment gage.

■Method with clearance measurement and adjustment with spacer (s)

Adjust the bearing internal clearance by following the procedure described below:

(1) Calculation of outer ring shrinkage (see Fig. 6.17)

- Calculate the interference at the fitting area Δd_{eff} between the outer ring and housing.

  Measure the housing bore diameter first, and then calculate the interference Δd_{eff} from the outer ring outside diameter listed on the bearing inspection sheet.

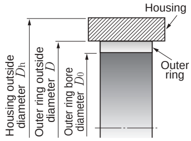

Fig. 6.17 Fit between outer ring and housing

EX. 1

Bearing outer ring outside diameter

ϕ150 mm (Inspection sheet = -0.005)

Housing bore diameter D

ϕ150 mm (measurement data = -0.007)

Interference at fitting area

Δd_{eff} = 0.002 (2 μm tight)

- Calculate the outer ring shrinkage ΔG with the formula (6.10).

$$\Delta G = \Delta d_{eff} \cdot \frac{D_0}{D} \cdot \frac{1-(D/D_h)^2}{1-(D_0/D)^2 \cdot (D/D_h)^2} \cdots\cdots\cdots\cdots \quad (6.10)$$

EX. 2

Housing outside diameter $D_h=\phi 200$, outer ring outside diameter $D=\phi 150$, outer ring bore diameter D_0 = $\phi 137$

$$\Delta G = 0.002 \cdot \frac{137}{150} \cdot \frac{1-(150/200)^2}{1-(137/150)^2 \cdot (150/200)^2} = 0.0015 \cdots\cdots \quad (6.11)$$

(2) Measurement of bearing position and bearing radial clearance on a temporarily mounted bearing

- Mount the bearing inner ring with the cage and rollers onto the tapered shaft (see **Fig. 6.18**).

  In this process, force the inner ring until its tapered bore face is fully seated, and then measure the distance between the shaft shoulder and inner ring side face (L_1).

NOTE: After mounting the inner ring, check that the bearing side face is square to the main spindle centerline.

- At this point, mount the outer ring, move the outer ring up and down by hand and then measure the internal clearance after mounting (Δr_1)(see **Fig. 6.19**).
- Calculate the estimated bearing clearance Δ_1 after press-fitting the outer ring into the housing with the formula (6.12). The result of the calculation reflects the outer ring shrinkage ΔG.

$$\Delta_1 = \Delta r_1 - \Delta G \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots \quad (6.12)$$

EX. 3

Internal clearance after mounting Δr_1= 0.030

Outer ring shrinkage ΔG= 0.0015

Estimated bearing clearance

Δ_1 = 0.030 - 0.0015 = 0.0285

(3) Adjustment of spacer width between shaft shoulder and inner ring

To adjust the bearing clearance to a predetermined target value (δ) after mounting, determine the spacer width L_n with the formula (6.13) (refer to **Figs. 6.20** and **6.21**).

$$L_n = L_1 + f\,(\delta - \Delta_1) \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots \quad (6.13)$$

$$(n=2,\ 3,\ 4 \cdots)$$

The value f in the formula (6.13) is found in the table below.

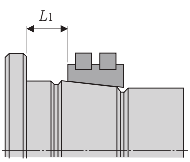

Fig. 6.18 Measurement of bearing position

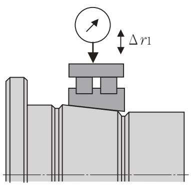

Fig. 6.19 Measurement of bearing radial clearance

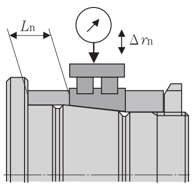

Fig. 6.20 Clearance measurement after insertion of spacer

Table 6.3 Value f

Value d_m/d_i	Value f
0 ~0.2	13
0.2~0.3	14
0.3~0.4	15
0.4~0.5	16
0.5~0.6	17
0.6~0.7	18

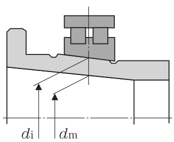

Fig. 6.21 Explanation of d_m/d_i

EX. 4

In the case of NN3020K, if d = dia. ϕ100, width B = 37, and $d_i = d$ + 1/12 · B/2,

then d_i = dia. ϕ101.54717.

If the targeted post-mounting clearance value δ = 0.015, L_1 = 15, d_m = dia. ϕ60, Δ_1 = 0.0285, then d_m/d_i= 60/101.5417 = 0.5909, and, therefore, f = 17.

Thus, the spacer width L_n between the shoulder and inner ring equivalent to δ = 0.015 will be the value shown by the formula below:

$$L_n = 15 + 17 \times (0.015 - 0.0285) = 14.7705$$

(4) Bearing clearance measurement after insertion of spacer (see Fig. 6.20)

Insert a spacer that satisfies the spacer width L_n between the shoulder and inner ring determined in the previous step, and tighten the inner ring until the spacer does not move. Next, move the bearing outer ring up and down by hand and measure the internal clearance after mounting (post-mounting internal clearance) Δr_n. The estimated bearing clearance Δ_n after press-fitting of the outer ring into the housing is determined with the formula below:

$$(n = 2, 3, 4 \cdots)$$
$$\Delta_n = \Delta r_n - \Delta_G \cdots\cdots \quad (6.14)$$

(5) Final adjustment for spacer width

- Repeat the steps (3) and (4) above to gradually decrease the spacer width L_n so as to adjust the post-mounting bearing clearance to the targeted clearance.
- By plotting the correlation between the spacer width and post-mounting clearance as illustrated in **Fig. 6.22**, the spacer width for the final targeted clearance will be more readily obtained.

  Positive clearance:
  All rollers are sliding rather than rolling.

  Clearance = 0:
  About half of the rollers are rolling but the rest are sliding.

  Negative clearance:
  All rollers are rolling.

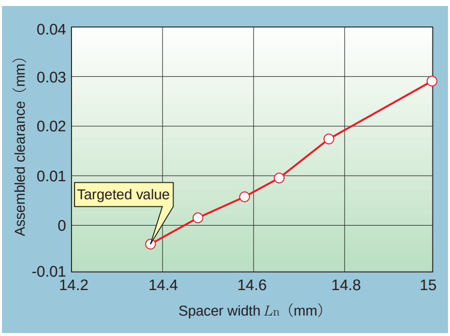

Fig. 6.22 Correlation between spacer width L_n and post-mounting clearance Δ_n

■Measurement with mounted internal clearance gage

The mounted internal clearance gage has a cylindrical ring, which has a cut-out so that the ring can be opened and closed. The bore surface of the ring is used as a location for measurement. The clearance at the location for measurement is proportional to the reading on the dial indicator. As illustrated in **Fig. 6.23**, the clearance gage consists of a ring gage, dial indicator, and attachment components. Its fixture protects the interference gage against possible deformation when not in use. For the measuring operation, detach the fixture.

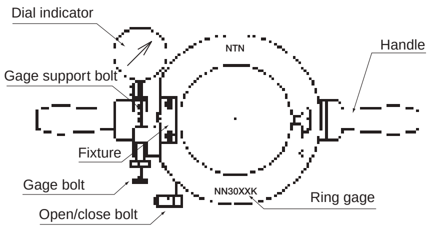

Fig. 6.23 Descriptions of various components on mounted internal clearance measurement gage

●Usage of mounted internal clearance gage

(1) Measurement of outer ring raceway diameter (bore diameter)

- Mount the outer ring into the housing.
  (For easy mounting, heat the housing.)
- Wait until the temperature of the outer ring is same as that of the inner ring, and then measure the outer ring raceway diameter (bore diameter). Take measurements at several points and calculate the average, and then zero the gage at this average value.

Photo 6.4

(2) Setup of mounted internal clearance gage

- Place the cylinder gage, onto the bore surface of clearance adjustment gage as shown in **Photo 6.5**, and adjust it with the open/close bolt so that its dial 1 is set to zero (see **Photo 6.6**).
- When the reading of dial 1 of the cylinder gage is zero, adjust the gage bolt so that the pointer of dial 2 points at the red mark (correction amount of the gage). (**Photo 6.6**)
  With the gage bolt, adjust the gage so that the short pointer is situated at the scale 2 position. (With the large size, insert the pin into the hole of the open/close bolt and make fine-adjustment.)

NOTE 1) **Photo 6.6** shows the inner ring and rollers. When the correction amount of the gage is adjusted, adjust it only with the thickness gage.
NOTE 2) The pointer of dial 2 is directed to the red mark. The purpose of this is to compensate clearance error caused due to the structure of mounted internal clearance gage. The correction amount can vary from gage to gage.
NOTE 3) When the pointer of dial 2 is in line with the red mark, the zero reading on dial 2 coincides with the zero bearing clearance.

(3) Setting up the mounted internal clearance gage on the main spindle

- Mount the inner ring onto the main spindle, and lightly tighten the bearing nut.
- Tightening the open/close bolt (see **Fig. 6.23**) on the clearance adjustment gage will cause the gage bore to expand.
  With the gage bore expanded by about 0.15 mm, insert the gage into the outside diameter portion of the roller set in the inner ring. Be careful not to damage the rollers (**Photo 6.7**).
- Loosening the open/close bolt will cause the gage bore to shrink.
  Loosen the open/close bolt to bring the gage bore into contact with the outside diameter of the ball set in the inner ring.
- Lightly swing the clearance adjustment gage in the circumferential direction to stabilize the pointer on the dial indicator.

(4) Setup of inner ring clearance

- Tighten the shaft nut of the main spindle. This should be done gradually to prevent shock loading.
- Tightening the nut further until the reading on the dial of the clearance adjustment gage becomes zero in case the clearance is aimed at 0 μm.
- Once the reading on gage gets zero, carefully swing the adjustment gage again to check that the measurement value is correct.
- Loosen the open/close bolt on the clearance adjustment gage to expand the gage bore and remove the gage from the inner ring.

(5) Determination of spacer width

- The inner ring should now be in the position where the reading on the dial of clearance adjustment gage was zero in step (4). By using a block gage, measure the distance between the inner ring side face and shaft shoulder (dimension ℓ in **Fig. 6.24**).
- Measure this dimension in at least three locations, and finally adjust the spacer width ℓ to the average of three measurements.
- Loosen and remove the shaft nut, inner ring spacer and inner ring from the main spindle.

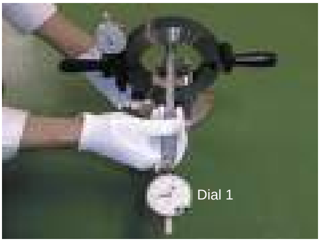

Photo 6.5

Photo 6.6

Photo 6.7

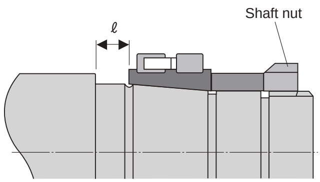

Fig. 6.24 Spacer width dimension

(6) Assembly and check of the mounted roller outside diameter

- Insert a spacer of width ℓ. Then insert the inner ring and mounting spacer and tighten the shaft nut.
- According to a procedure similar to that in steps (3) "Setting up the mounted internal clearance gage on the main spindle" and (4) "Setup of inner ring clearance", check the mounted roller outside diameter and the clearance setting. Note this process is only a re-check procedure, and may be omitted once the clearance measurements fall in a smaller range.

●Clearance correction factor and mounted internal clearance reading

(1) Clearance correction factor

Because of the structure of the **NTN** mounted internal clearance adjustment gage, the ratio of the clearance reading on location for measurement to the reading on dial indicator is 1:2.5 (clearance indication factor). The clearance reading on the dial indicator is 2.5 times as large as the remaining internal clearance. For reference, a clearance reading conversion table is given in **Table 6.4**.

NOTE: Note that the clearance correction factor of certain bearing numbers is not 1:2.5. Correction factor is given on the table of inspection results.

(2) Remaining internal clearance (where clearance indication value 1:2.5)

The reading on the dial indicator is converted into a mounted internal clearance in the following manner:

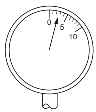

Fig.6.25

- CASE 1: The reading relative to the zero point is in the clockwise direction (CW) (**Fig. 6.25**). The value of the mounted internal clearance (+) is 1/2.5 times as large as the reading on dial gage.
  Reading on dial gage in **Fig. 6.25** = 2.5
  Remaining internal clearance = 2.5/2.5 = (+)1 μm
- CASE 2: The reading relative to the zero point is in the counterclockwise direction (CCW) (**Fig. 6.26**). The value of the mounted internal clearance (-) is 1/2.5 times as large as the reading on dial gage.
  Reading on dial gage in **Fig. 6.26** = 5.0
  Remaining internal clearance = 5.0/2.5 = (-)2 μm

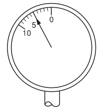

Fig.6.26

Table 6.4 Clearance reading conversion table

Reading on dial gage (μm)	Remaining internal clearance on location for measurement (μm)	Reading on dial gage (μm)	Remaining internal clearance on location for measurement (μm)
0.5	0.2	5.5	2.2
1.0	0.4	6.0	2.4
1.5	0.6	6.5	2.6
2.0	0.8	7.0	2.8
2.5	1.0	7.5	3.0
3.0	1.2	8.0	3.2
3.5	1.4	8.5	3.4
4.0	1.6	9.0	3.6
4.5	1.8	9.5	3.8
5.0	2.0	10.0	4.0

●Setup of mounted internal clearance

When setting the mounted internal clearance to a specific negative or positive value, the zero point on dial indicator by a value [targeted clearance multiplied by 2.5] may be shifted prior to the setup of the clearance adjustment gage. (In case that the mounted clearance value is divided by the correction factor, it is not necessary to the value [targeted clearance multiplied by 2.5])

(2.5: clearance correction factor)

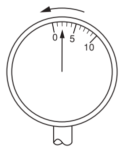

Fig. 6.27 Adjustment for negative clearance (remaining internal clearance: -0.8 μm)

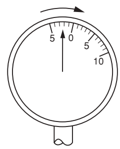

Fig. 6.28 Adjustment for positive clearance (remaining internal clearance: +1.0 μm)

Precautions for using and storing the mounted internal clearance adjustment gage

When using the mounted internal clearance adjustment gage, follow the precautions described below:

- When transferring the outer ring raceway diameter measured with the cylinder gage to the mounted internal clearance adjustment gage, use the adjustment gage in a vertical attitude (**Photo 6.8**).
- When not using the mounted internal clearance adjustment gage, place it in a horizontal attitude (**Photo 6.9**). Also, after completion of clearance measuring operation, apply rust-preventive oil to the internal clearance adjustment gage and store in a dry location.

Photo 6.8 Vertical storage attitude

Photo 6.9 Horizontal storage attitude

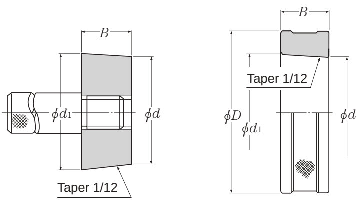
⑧ Tapered bore cylindrical roller bearing and main spindle taper angle

In order for a precision bearing to perform as designed, it must be correctly mounted to a shaft and housing. In particular, when employing a tapered bore cylindrical roller bearing, accurate finish for the tapered main spindle and appropriate fit between the bearing bore and the main spindle are very important to ensure high accuracy of the main spindle. **NTN** recommends that the customer use the **NTN** tapered shaft ring gage, which that is finished to same accuracies as the bearing, so that the customer can achieve higher precision. **NTN** also offers a plug gage so that the customer can check the accuracy of the ring gage.

■Taper gage for precision roller bearings

Each **NTN** precision cylindrical roller bearing taper gage consists of a female gage and a male gage (plug gage) (**Fig. 6.29**).

Using blue paste or an equivalent as well as a ring gage, check the fit of the bearing bore with the main spindle taper. The correct fit between the main spindle and the bearing leads to higher accuracy of the main spindle. The plug gage is intended to check the accuracy of the associated ring gage. Use the plug gage to verify the taper accuracies of the associated ring gage (**Fig. 6.30**).



Plug gage (TA)　　Ring gage (TB)

Fig. 6.29 Taper gage

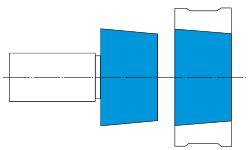


Fig. 6.30 Blue paste on taper gage

■Taper angle

NTN machines the tapered bore of its cylindrical roller bearings and the taper angle of its taper gages according to the tolerances below:

- Nominal taper angle 1/12 (4° 46' 18.8")
- Tolerance for precision roller bearing with 1/12 taper angle is +12"±12" (JIS class 4 and 2)
- Targeted tolerance for taper gage 1/12 is +9".

Usually, Using blue paste between the tapered bore of a cylindrical roller bearing and a plug gage exhibits a strong contact mark on the small diameter side as show in **Fig. 6.31**. This is because **NTN** has slightly adjusted the taper angle of the bearing bore to accommodate for the difference in thickness of the inner ring below each row of rollers.

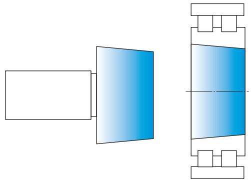

Fig. 6.31

■Checking main spindle taper with ring gage

When checking the main spindle taper angle with a ring gage, perform the following steps.

- Thoroughly clean the surface of the ring gage, and apply a thin layer of blue paste to four equally-spaced points.
- Clean the tapered surface of the shaft, and gently insert into the ring gage.
- The ring gage to be lightly turning it.
- Check the patterns of blue paste deposited on the shaft surface.
- At this point, attach a strip of clear adhesive tape onto each blue paste spot, and peel off each strip.
  Attach strips of adhesive tape onto white paper and check how much blue paste was deposited onto each point. Check that more than 80% of the applied blue paste was deposited on the tapered surface.

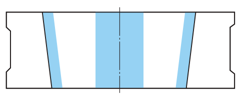

Fig. 6.32 Application of blue paste to ring gage

⑨ Running-in operation for main spindle bearings

Run-in is important for ensuring smooth operation of grease-lubricated main spindle bearings.

The following two modes of running-in are recommended:

(1) The bearing speed is gradually increased in steps. After the temperature is saturated at each speed setting, the speed is increased to the next step (**Fig. 6.34**).

(2) The bearing is run for one minute at around the maximum operating speed of the spindle. This cycle is repeated two or three times (**Fig. 6.35**) as needed.

(1) is the ordinary method used, however it takes slightly longer to reach the maximum operating speed of the spindel. In contrast, (2) can shorten the running-in time, however higher risk of sudden bearing temperature increase is considerable, so that running speed and its holding time must be set carefully.

Generally, the temperature of a main spindle bearing is measured on the front cover. The temperature difference across the bearing outer ring and front cover reaches 2 to 3˚C, and at the same time, the temperature difference between the hottest rolling element and the inner ring raceway surface seems to reach 50 to 10˚C. For this reason, **NTN** recommends that the machine is stopped if the temperature on front cover reaches approximately 60˚C. The machine should be allowed to cool off before the running-in operation is restarted.

7. Lubrication of Bearings

In a bearing, lubrication forms a thin oil film on both rolling and sliding surfaces to prevent metal-to-metal contact. The benefits of lubrication can be summarized as follows:

(1) Alleviation of friction and wear
(2) Removal of heat due to friction
(3) Longer bearing life
(4) Rust prevention
(5) Protection against contamination by foreign material

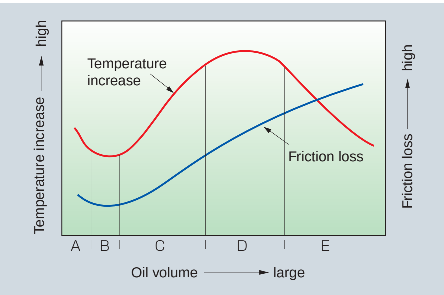

Fig. 7.1

Table 7.1 Oil volume, friction loss and bearing temperature (Fig. 7.1)

Zone	Features	Typical lubrication method
A	With an extremely low volume of oil, partial metal-to-metal contact occurs between the rolling elements and raceway surface, possibly leading to abnormal wear and bearing seizure.	——
B	A uniform, uninterrupted oil film is formed. Friction is minimal and bearing temperature is kept low.	Grease lubrication Oil mist lubrication Air-oil lubrication
C	Even with a greater oil volume, heat generation and cooling are in balance.	Circulating lubrication
D	Temperature increase is constant regardless of oil volume.	Circulating lubrication
E	A further increase in oil volume contributes to a significant cooling effect, and the bearing temperature drops.	Forced circulating lubrication Jet lubrication

To achieve the full lubricating effect, it is necessary to use a lubricating system suited to the operating conditions, select a quality lubricant, remove dust from the lubricant, and design an appropriate sealing structure to prevent contamination as well as lubricant leakage.

The main spindle of a machine tool usually uses an extremely low volume of lubricant so heat generation from stirring of the lubricant is minimal.

Fig. 7.1 summarizes the relationships between oil volume, friction loss, and bearing temperature.

The lubrication methods available for bearings in a machine tool include grease lubrication, oil mist lubrication, air-oil lubrication, and jet lubrication. Each method has unique advantages. Therefore, the lubricating system that best suits the lubrication requirements should be used.

Tables 7.1 and **7.2** summarize the features of various lubrication methods.

Table 7.2 Evaluation of various lubricating systems

Lubrication method / Criterion	Grease lubrication	Oil mist lubrication	Air-oil lubrication	Jet lubrication
Handling	☆☆☆☆☆	☆☆☆	☆☆☆	☆☆
Reliability	☆☆☆	☆☆	☆☆☆	☆☆☆☆☆
Temperature increase	☆☆	☆☆	☆☆☆	☆☆☆☆☆
Cooling effect	☆	☆☆	☆☆☆	☆☆☆☆☆
Sealing structure	☆☆	☆☆☆	☆☆☆	☆
Power loss	☆☆☆	☆☆☆	☆☆☆	☆
Environmental contamination	☆☆☆	☆	☆☆	☆☆☆
Allowable $d_m n$ value ❶	1.4×10^6	2.2×10^6	2.5×10^6	4.0×10^6

Legend ☆☆☆☆ : Excellent ☆☆☆ : Good ☆☆ : Fair ☆ : Poor

❶ The permissible $d_m n$ values are approximate values:
$d_m n$: pitch circle diameter across rolling elements [mm] multiplied by speed [min^{-1}]

① Grease lubrication

Grease lubrication is the most common, as it simplifies the main spindle structure more than other lubricating systems. With an adequate amount of quality grease prefilled, this system can be used over a wide range of speed. The allowable maximum speed varies with the type and size of bearing: for a high-speed angular contact ball bearing, the $d_m n$ value should be 1.4×10^6 as a guideline. For applications exceeding this range, consult **NTN** Engineering.

■Grease types

A lithium-based grease, with a mineral oil base, is commonly used as a lubricant for rolling bearings. Its operating temperature range is -30˚C to 130˚C.

When the temperature increase must be limited, as with the main spindle of a machine tool, **NTN** recommends the use of a synthetic-oil-based grease (diester, diester+mineral oil) which penetration is NLGI grade 1 or 2.

Table 7.3 lists technical data for greases commonly used for machine tool main spindles.

■Amount of grease required

Usually, a bearing for the main spindle of a machine tool requires that grease volume be low so heat generated by the stirring of the grease during high-speed operation is minimal. A guideline for the amount of grease used for a main spindle bearing is given below.

- Angular contact ball bearing
  ($d_m n$ value $\leqq 0.65 \times 10^6$); 15% of bearing free space
  ($d_m n$ value $> 0.65 \times 10^6$); 12% of bearing free space
- Cylindrical roller bearing; 10% of bearing free space
- Tapered roller bearing; 15% of bearing free space

The space in the bearing typically used for main spindles are listed in dimension tables. Determine a fill amount by referring to the relevant dimension table.

Before filling a bearing with grease, remove the rustproof coating from the bearing with clean wash oil and allow the bearing to dry completely. Then fill and uniformly distribute an appropriate amount of grease in the bearing with an syringe, plastic bag, etc.

Table 7.3 Typical greases for machine tool main spindle bearings

Grease brand	SE-1	MP-1	ISOFLEX NBU15	Stabllugs NBU 8EP	Multemp LRL3	Multemp PS2	ISOFLEX LDS18

NTN grease code	L749	L448	15K	L135	12K	1K	6K

② Air-oil lubrication

Air-oil lubrication (also known as oil-air lubrication or oil and air lubrication) is widely adopted for main spindle bearings in order to cope with the higher speed and precision of machine tools and to ensure more reliable lubrication.

Air-oil lubrication employs a method by which compressed air is used to provide lubricating oil in precisely controlled amounts. Generally, an air-oil lubrication unit a volumetric piston-type distributor that accurately meters the required minimum amount of lubricating oil and provides it at optimal intervals controlled by a timer.

■Special features of air-oil lubrication

Air-oil lubrication has the following advantages over conventional oil mist lubrication:

- Accurately supplies a minimal amount of oil.
- Can be adjusted to provide the proper amount of lubricant for individual bearings.
- No limitations exist regarding lubricant viscosity and extreme pressure additives.
- Compressed air helps cool the bearing.
- Variations in the distance and height of lubrication points do not affect lubrication efficiency.
- Health hazards of oil mist are minimized.
- Low oil consumption.
- Use of compressed air can prevent contamination of the bearing by other coolants.
- The recommended oil viscosity is 10 to 32 mm^2/s.

■Example of an air-oil lubrication unit

Fig. 7.2 shows the structure of an air-oil lubrication unit.

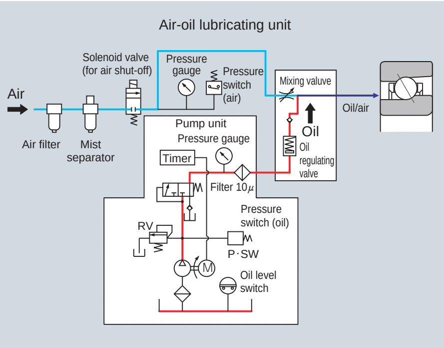

Fig. 7.2 Air-oil lubricating system

■Air-oil lubrication nozzle spacer

Air-oil lubrication requires a specialized nozzle because it supplies the lubricating oil to the inside of the bearing by means of compressed air. (**Fig. 7.3**)

A nozzle with a hole diameter of 1.0 to 1.5 mm and a length 4 to 6 times the hole diameter is recommended.

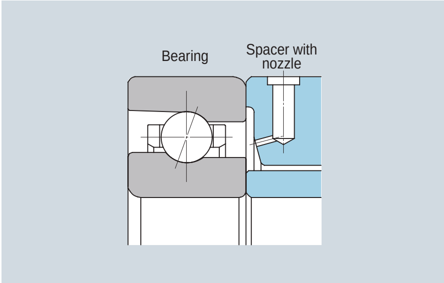

Fig. 7.3 Feed system for air-oil lubrication

■Exhaust method for air-oil lubrication

Air-oil lubrication uses a large volume of air to feed lubricating oil to the bearing. Therefore, it is essential that the air fed into the bearing be allowed to escape. If the air is not smoothly exhausted, the lubricating oil will remain in the bearing and possibly contribute to bearing seizure. In the design stage, remember to allow ample space on the exhaust side of the bearing in order to increase exhaust efficiency and provide a larger oil drain hole to ensure smooth airflow. In addition, for types that allow for repositioning of the spindle, it is recommended that the shoulder dimensions of all parts is designed to prevent lubricating oil from flowing back into the bearing after a change in the attitude of the main spindle. Unnecessary dimensional differences can also contribute to stagnancy of the lubricating oil.

■Recommended targeted position with nozzle

③ Jet lubrication

With this lubricating system, a high-speed jet of lubricant is injected into the bearing from the side. This is the most reliable lubricating technique and is typically used on the main spindle bearings of jet engines and gas turbines. It is currently capable of a $d_{m}n$ value of up to approximately 4.0×10^6.

When used as a lubricating system for the main spindle of a machine tool, it can minimize the temperature increase of the bearing. However, the resultant torque loss is great, as a large amount of oil is supplied to each bearing. Therefore, this arrangement requires a powerful motor to drive the main spindle. Low viscosity oil (2-3 mm^2/s) is used.

Fig. 7.9 shows examples of the temperature increase with air-oil lubrication and jet lubrication, while **Fig. 7.10** graphically plots test results of power loss.

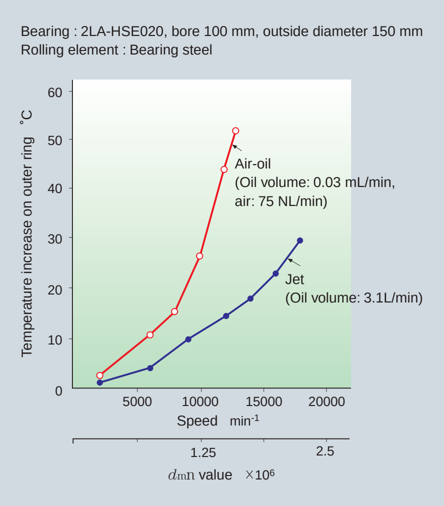

Fig. 7.9 Comparison of temperature increase of outer ring with air-oil lubrication and jet lubrication

(The temperature increase with air-oil lubrication is relative to room temperature; the temperature with jet lubrication is relative to lubricant temperature.)

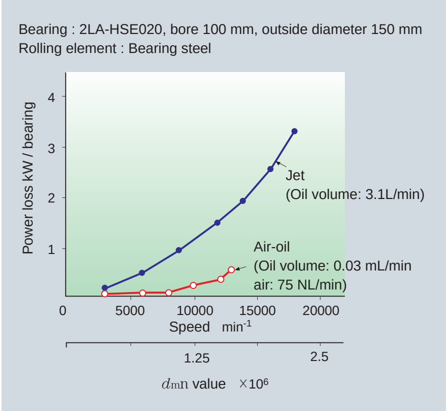

Fig. 7.10 Comparison of power loss with air-oil lubrication and with jet lubrication

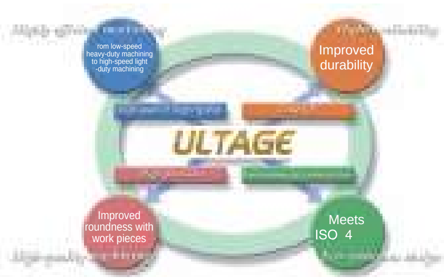
8. New Technologies

① The new ULTAGE Series of super-high-speed precision bearings for machine tool main spindles

NTN has responded to need for improved efficiency, reliability, quality and environmental responsibility for machine tools by developing the ULTAGE Series of super-high-speed precision bearings. This new line of bearings demonstrates excellent performance thanks to the optimal internal design; a new approach to surface quality; and the use of special materials, special grease, and seals on both sides.

ULTAGE is the name for **NTN**'s goal of achieving the ultimate performance with precision bearings, and expresses the "ULTIMATE" performance on any type of "STAGE."



■Concept

Our ideal is to offer a super high-speed precision bearing that offers excellent reliability while remaining eco-friendly.

【 Design 】

The internal bearing design has been optimized to cope with varying applications and operating conditions in order to realize high speed and high rigidity, limited temperature increase, high precision, energy saving and low noise emission. It performs optimally in a variety of situations.

【 Material 】

Adoption of special material and a special surface modification technique has resulted in greatly enhanced reliability.

【 Lubrication 】

Use of unique eco-conscious technology and special grease contributes to decreased pollution and enhanced energy savings.

【 Precision 】

Our super high-precision technology, in conjunction with our proven precision bearing technology, will help attain further improved precision.

② New material and new surface modification technology

The ULTAGE super high-speed precision bearing series for machine tool main spindles employs a special material that boasts excellent anti-seizure properties and wear resistance, as well as a unique surface modification technique.

■Life under normal temperatures

The test results obtained from point contact test pieces under greater loading are graphically plotted in **Fig. 8.1**.

【Test conditions】

Test piece	φ12×22 mm cylindrical roller
Ball	φ19.05 (3/4")
Max. contact stress	5.88 GPa
Loading frequency	46,240 cycles/min
Lubricant	Turbine VG56 (oil bath)

【Schematic of test rig】

	L_{10} (×10^7cycles)	Life ratio
SUJ2	6.3	1
Special material	79.8	12.7

The rolling fatigue life of the special material is approximately 13 times as long as that of SUJ2.

Fig. 8.1 Life test results with point contact test pieces

■Life under high temperature

The test results obtained from thrust-type test pieces at 200˚C are graphically plotted in **Fig. 8.2**.

【Test conditions】

Test piece	φ47×φ29×t7 flat plate
Ball	φ6.35（1/4"）Ceramic ball
Max. contact stress	5.5 GPa
Loading frequency	3,000 cycles/min
Oil temperature	200˚C
Lubricant	Ether-based oil

【Schematic of test rig】

	L_{10} (×10⁵cycles)	Life ratio
SUJ2	9.1	1
Special material	No flaking	>30

The rolling fatigue life of the special material at a high temperature of 200˚C is more than 30 times as long as that of SUJ2.

Fig. 8.2 High temperature life test results with thrust-type test pieces

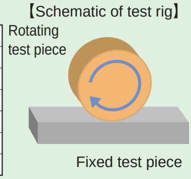
■ Improved wear resistance

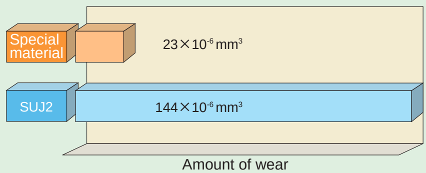
Test results with a Sawin type friction and wear test machine are illustrated in **Fig. 8.3**.

【Test conditions】

Speed	4775 min^{-1}
Peripheral speed	10 m/s
Test duration	10 min
Max. contact stress	2.0 GPa
Lubricant	VG2
Rotating test piece	Material being tested
Fixed test piece	Si_3N_4

【Schematic of test rig】





The wear resistance of the special material is 6 times better than that with SUJ2.

Fig. 8.3 Test results with Sawin type friction and wear test machine

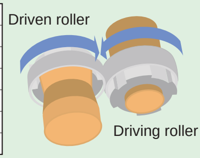
■ Improved anti-seizure property

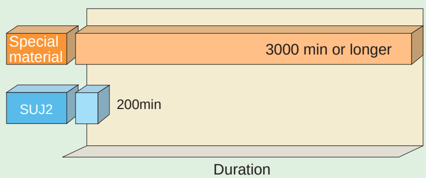
Test results with a two roller testing machine are illustrated in **Fig. 8.4**.

【Test conditions】

Driving side speed	200 min^{-1}
Driven side speed	120 min^{-1}
Sliding velocity	10.1 m/s
Max. contact stress	2.9 GPa
Lubricant	VG2
Driving roller	Material being tested
Driven roller	Material being tested

【Schematic of test rig】





The anti-seizure property of the special material is more than 15 times better than as that with SUJ2.

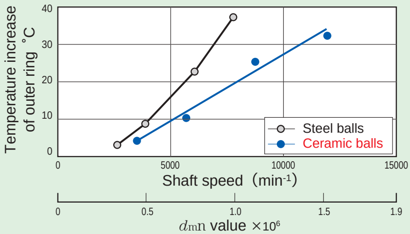
Fig. 8.4 Test results with a two roller testing machine

■Adoption of ceramic balls

A comparison of temperature increase, which can vary depending on the material of rolling element, is illustrated in **Fig. 8.5.**

【Test conditions】

Test bearing	Basic bearing number HSE020 (φ100×φ150×24×2 rows)
Preload	2.5 kN (constant pressure preloading)
Lubrication	Grease
Outer casing cooling	None



The ULTAGE series bearings employ well-proven ceramic balls to efficiently limit temperature increase.

Fig. 8.5 Comparison of temperature increase with steel and ceramic rolling elements

③ Environmentally conscious technology

The eco-friendly ULTAGE Series is available in two specifications: an eco-friendly air-oil lubrication design that offers energy savings by reducing air and oil consumptions; and a grease-lubricated, sealed design that reduces environmental impact by employing a grease lubrication system that is capable of higher-speed operation.

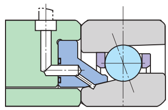
Required functions for the main spindle bearing

Speed | Rigidity | Durability | Precision | Eco-friendly design

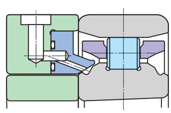
For main spindles

Eco-friendly air-oil lubrication

HSL type



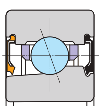
N10HSL type



Reduced air/oil consumption contributes to energy savings.

Grease lubrication

High-speed BNS LLB type



Sealed

Sealed

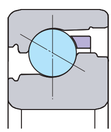
Combines durability with ease of handling.

2A-BST type



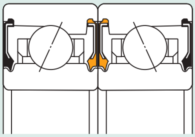
Durability

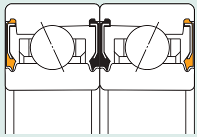
■ Grease-lubricated sealed angular contact ball bearings

(1) Ease of handling

ULTAGE angular contact ball bearings with seals are grease-prefilled bearings. No grease filling is necessary; you need only wipe off the rust-preventive oil before assembly. Seals of different colors are employed to differentiate the front and back. The black front face and orange back face are easily identified, which also makes it easy to orient the bearings in combinations (**Table 8.1**).

Table 8.1 Bearing combinations and seal colors

DB set (back-to-back)		DF set (face-to-face)	
Orange seal + Orange seal		Black seal + Black seal	
			




(2) Suggestions for simplified spindle structure

The ULTAGE Series sealed angular contact ball bearing makes possible high-speed operation with grease lubrication thanks to optimized internal design. Grease lubrication with minimal mist splash simplifies main spindle structure and contributes to lower environmental impact as well as cost reduction (**Fig. 8.6**).

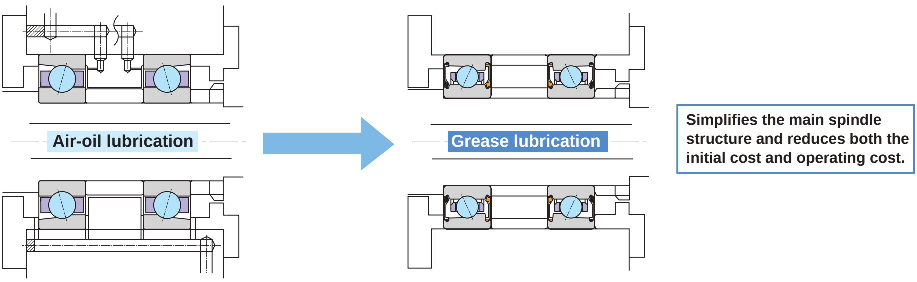


Fig. 8.6 Alteration to lubrication system (air-oil lubrication to grease lubrication)

■Eco-friendly air-oil lubricated angular contact ball bearings and cylindrical roller bearings

When combined with the eco-friendly nozzle, the eco-friendly air-oil lubricated angular contact ball bearing (HSL/HSFL Series) or cylindrical roller bearing (N10HSL[K] Series) can reduce the emissions of oil mist and noise.

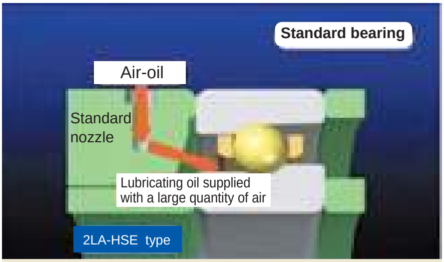
(1) Reduction of oil mist

The eco-friendly air-oil lubricated bearing does not spray compressed air from the nozzle; instead, it uses the centrifugal force of the rotating inner ring to supply lubricating oil into the bearing. For this reason, this type of bearing conserves both air and oil. In addition, it reduces the amount of oil mist emitted from the labyrinth seal of the spindle. The following photographs reveal the difference between the amount of oil mist emitted from the conventional standard bearing and that emitted from the eco-friendly bearing.

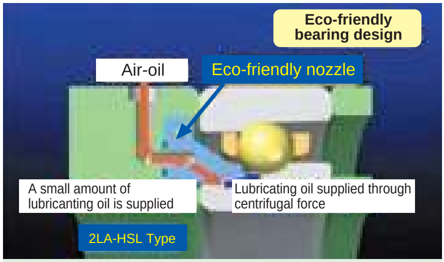
The lubricating oil discharged with air passes through the inside of the bearing and is then exhausted as a large volume of mist.

The lubricating oil exhausted from the bearing in the mist state is collected through the discharge port of the main spindle housing, but some of the oil mist leaks from the main spindle labyrinth seal and contaminates the immediate environment around the machine.

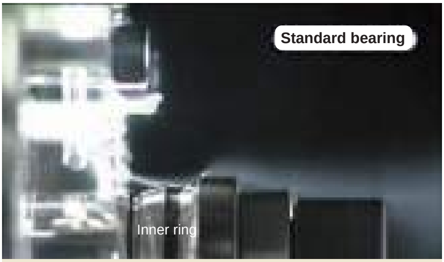
Adoption of the eco-friendly bearing therefore improves the working environment.



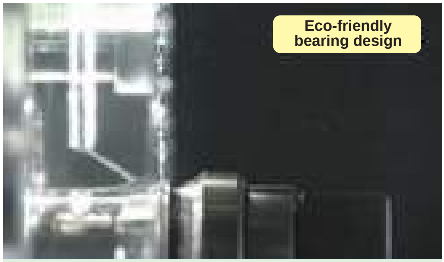
Conventional bearings consume a great deal of air when supplying lubricating oil to the bearing.



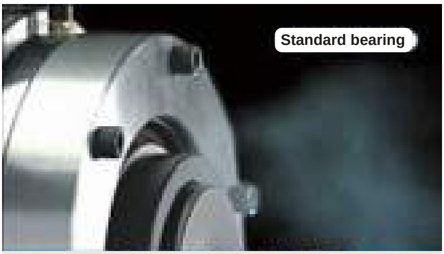
The eco-friendly type uses centrifugal force to supply lubricating oil into the bearing.



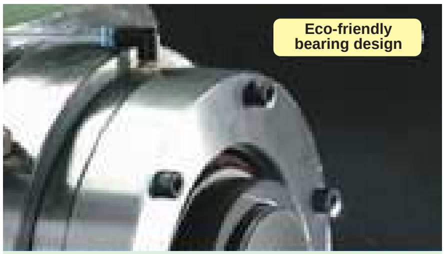
Atomized when emitted from the nozzle



The oil emitted from the nozzle is in a liquid state.



A large amount of oil mist passes through the bearing, contaminating the working environment.



The amount of oil mist is reduced, minimizing environmental contamination in work areas.

(2) Noise Reduction

The standard air-oil lubrication method uses air to supply a slight amount of oil. It also uses a special nozzle spacer, as shown in **Figs. 8.7** and **8.9**.

In addition, this method uses a nozzle measuring 1 to 1.5 mm in diameter to supply oil to the raceway surface of the bearing at the rate of 30 to 40 NL/min/bearing. To supply this oil, the nozzle emits compressed air as a jet to break the air barrier of the bearing, which is created when running at high speed. In this way, the air is used as a tool for supplying oil. The eco-friendly bearing developed by **NTN** reduces the amount of air consumed, thus reducing the whistling noise of the flowing air. The mechanism used in this type of bearing is as follows: the centrifugal force of the bearing inner ring feeds a small amount of oil from the nozzle to the raceway surface of the bearing along the tapered surface. (**Figs. 8.8** and **8.10**).

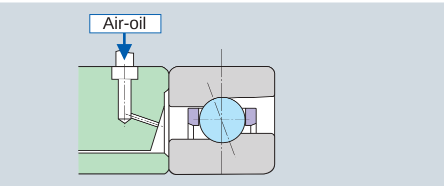


Fig. 8.7 Standard nozzle

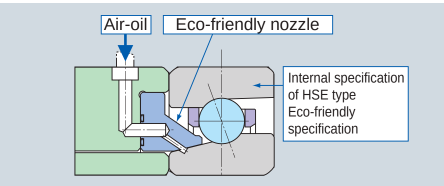

Fig. 8.8 Eco-friendly type nozzle

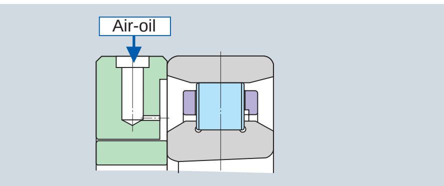

Fig. 8.9 Current bearing N10HS type

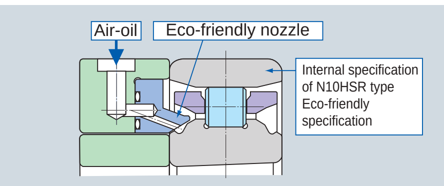

Fig. 8.10 ULTAGE N10HSL type

Since the function of the compressed air is only to deliver lubricating oil to the cavity of the inner ring, a large quantity of air is not required. In addition, since the air used to supply the oil is released between the tapered surfaces, the whistling noise of air is also reduced.

When the eco-friendly bearing is employed, the noise is reduced by 6 to 8 dBA.

Example:

In the high-speed region in excess of 10,000 min^{-1}, noise is reduced by 6 to 8 dBA (**Fig. 8.11**).

【Test conditions】

Test bearing	**5S-2LA-HSFL020 (eco-friendly bearing)** 5S-2LA-HSF020 (φ100×φ150×24, 2 rows)
Shaft speed	20,000 min^{-1}
Preload	2.5 kN (constant pressure preloading)

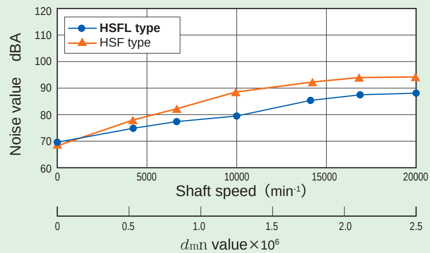

Fig. 8.11 Comparison of noise values

The eco-friendly bearing is particularly good for reducing “screeching” noise. The high-frequency component of the noise generated at high speeds is well attenuated. The reason for this is as follows: when the air jet emitted from the standard nozzle hits the rolling elements, a high-pitched noise is generated; in contrast, the eco-friendly nozzle does not emit air on the rolling elements, which reduces screeching noise.

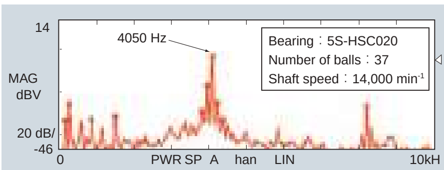

Fig. 8.12 Frequency characteristics of bearing noise (standard nozzle)

Main Spindle Bearings

9. Angular Contact Ball Bearings for Radial Loads CONTENTS

9. Angular Contact Ball Bearings for Radial Loads

Angular contact ball bearings for radial loads used in machine tools are bearings which inner and outer rings cannot be separated. This type of bearing includes series 78, 79U, 70U, 72, HSE9, HSE0, BNS9, BNS0, BNT9, BNT0 and BNT2. For angular contact ball bearings, an imaginary straight line connecting the contact points between the balls and inner and outer rings forms an angle with the radial axis. The optimal contact angle can be selected to meet functional requirements such as high speed or high rigidity. The available contact angles are 15° (contact angle symbol "C"), 20° (no symbol), 25° ("AD"), and 30° (no symbol). (**Fig. 9.1**)

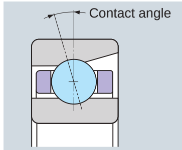

Fig. 9.1 Contact angle

① Features of various types

Open bearings

■Standard angular contact ball bearings (78, 79, 70 and 72 Types)

Standard angular contact ball bearings are available in four types: 78, 79, 70 and 72. Types 79 and 70 include the 79U and 70U ULTAGE Series, which accommodate high speed and low temperature rise with optimized specifications of the internal design. For these types, three contact angles are available: 15° (contact angle symbol "C"), 25° ("AD"), and 30° (no symbol). The contact angle of 25°, however, is also available with 79U and 70U types. This bearing series has an accuracy of JIS class 5 or better. The features include high speed, high rigidity, and high load capacity. Some models incorporate ceramic balls.

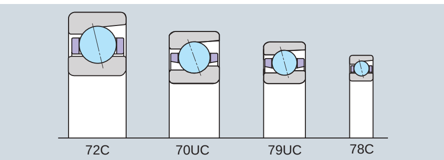

Fig. 9 2. Standard angular contact ball bearings

■High-speed angular contact ball bearings (HSE type)

High-speed angular contact bearings are available in two types: HSE9 and HSE0. The boundary dimensions of this bearing series are determined according to the JIS dimension series (9, 0), and three types of contact angles are available: 15° (contact angle symbol "C"), 20° (no symbol), and 25° ("D"). The accuracy of this ball bearing series is JIS class 5 or better, and the ball diameter is smaller than that of the standard angular contact ball bearing in order to accommodate high speeds. The outer surface of the inner ring and the bore of the outer ring are relieved on one side, and this bearing series employs an air-oil lubrication system to ensure smooth oil flow. In addition, it employs special materials, and its surface is modified to protect the bearing from wear and seizure more positively. The HSE type bearing is available with either steel balls or ceramic balls.

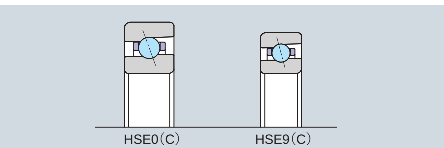

Fig. 9.3 High-speed angular contact ball bearings

■Ultra-high-speed angular ceramic ball bearings (HSF type)

The HSF0 type ultra-high-speed angular contact ceramic ball bearing employs smaller balls than the HSE0C type to ensure rigidity and prevent temperature rise. In addition, it employs a contact angle of 25° to accommodate the reduction in contact angle caused by centrifugal force during operation.

These features allow the use of an air-oil lubrication system ($d_m n$ value $< 2.6 \times 10^6$) in a speed region that was previously possible only with a conventional jet lubrication system.

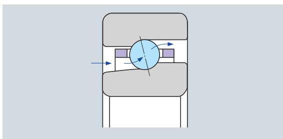

Fig. 9.4 Ultra-high-speed angular contact ball bearings

■Eco-friendly air-oil lubricated angular ball bearings (HSL and HSFL types)

For eco-friendly air-oil lubricated angular contact ball bearings (HSL and HSFL types), the angle of the inner ring outer surface (counterbore area) is optimized compared with that of HSE and HSF types. In addition, these angular contact ball bearings are dedicated to air-oil lubrication by adopting a circumferential groove and an eco-friendly nozzle. They accommodate the same high speed as HSE and HSF types while being more eco-friendly. They generate less noise and conserve energy since they consume less air and oil. The accuracies of these bearing types are JIS class 5 or better. For the HSL type, three contact angles [20˚ (no symbol), and 25˚ ("AD")] are available. For the HSFL type, however, only one contact angle (25˚) is available. The HSFL type utilizes a specially designed eco-friendly nozzle.

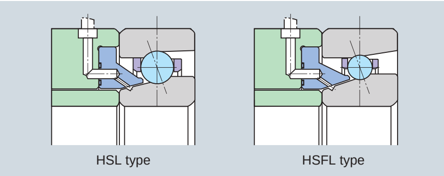

Fig. 9.5 Eco-friendly angular contact ball bearings

■Air-oil lubricated high-speed angular ball bearings with re-lubricating hole on the outer ring (HSEW type)

HSEW type is designed based on HSE type as high speed angular contact ball bearing for air-oil lubrication with lubrication hole on outer ring.

Spacers next to these bearings don't need length for nozzle to be mounted, and can be short. These short spacers have an effect on compact design and rigidity of spindle as a result of shortened distance between bearing and tool.

In addition, direct air-oil supply through the hole on outer ring achieves improved lubricating reliability with low air flow rate and small oil consumption.

JIS Class 5 or higher bearing accuracy is applied on this type. Two kind of contact angles are available, 20˚ (no suffix) and 25˚ (AD).

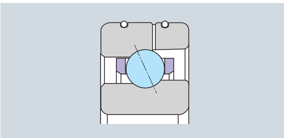

Fig. 9.6 Ultra-high-speed angular contact ball bearings

■High-speed angular contact ball bearings for grinding machines/motors (BNT type)

The boundary dimensions of high-speed angular ball bearings for grinding machines/motors (BNT type) are determined according to the JIS dimension series (9, 0, 2). For this bearing type, only one contact angle (15˚, no symbol) is available, and the bearing accuracies are JIS class 5 or better. This bearing uses mainly air-oil lubrication and oil mist lubrication. The features of this bearing are high speed capability and high load capacity. This type of bearing is available with either steel balls or ceramic balls.

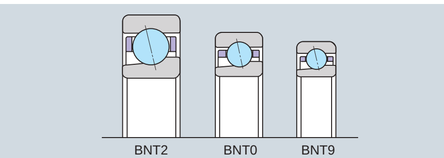

Fig. 9.7 High-speed angular contact ball bearings for grinding machines/motors

Sealed bearings

■Standard grease-lubricated sealed angular contact ball bearings (79LLB/70LLB types)

The standard grease-lubricated sealed angular contact ball bearings are available in 79 and 70 series. Non-contact rubber seals are mounted on both sides and special grease is used. As a result, these bearings accommodate high speed, offer prolonged service life, and help to maintain a comfortable working environment. These bearings are available in contact angles of 15˚ (contact angle symbol "CD") and 25˚ ("AD") and with a special accuracy of P42 (JIS class 4 dimensional accuracy and JIS class 2 running accuracy). Since they are prefilled with grease, these bearings require no cleaning before use and are therefore easy to handle. They are available with either steel balls or ceramic balls.

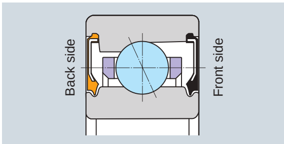

Fig. 9.8 Standard grease-lubricated sealed angular contact ball bearings

■High-speed grease-lubricated sealed angular contact ball bearings (BNS type)

High-speed grease-lubricated sealed angular contact ball bearings (BNS type) are available with the boundary dimensions of HSE type. Non-contact rubber seals are incorporated on both sides and its inner structure is optimized. It is also prefilled with a special grease to achieve high speed capability, inhibit temperature rise, extend service life and create a comfortable working environment. This bearing type is available in contact angles of 15˚ (contact angle symbol "CD"), 20˚ (no symbol), and 25˚ ("AD"). Bearing accuracy is JIS class 4 or better. The bearing ring is made of a special material, and the surface is modified to protect the bearing from wear and seizure. Since this type is prefilled with grease, it requires no cleaning before use and is therefore easy to handle. It is available with either steel balls or ceramic balls.

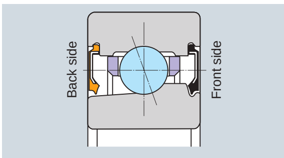

Fig. 9.9 High-speed grease-lubricated sealed angular contact ball bearings

Note 1) Cage design is subject to change without notice. For detailed information, contact **NTN** Engineering.
Note 2) The polyamide plastic cage can be used up to the following rotating speeds depending on the material of the rolling element. The $d_m n$ value 0.9×10^6 for bearing steel and $d_m n$ value 1.0×10^6 for ceramics. Machined phenol resin cages must be used if the allowable rotational speed of the dimensions listed exceeds the figures above. For detailed information, contact **NTN** Engineering.

⑤ Internal clearance and standard preload of duplex angular contact ball bearings

The initial internal clearance or preload for duplex angular contact ball bearings is determined with consideration for two factors: temperature rise during operation and the rigidity and accuracy required after assembly or during operation.

The internal clearance of the bearing may be significantly affected during operation due to three factors: the reduction in clearance caused by fits, the temperature difference between the inner and outer rings during operation, and the effects of centrifugal force. Depending on the initial internal clearance, a significantly reduced clearance may result in extreme temperature rise, vibration, noise, and short service life. In addition, seizure may result in some cases. For this reason, it is important to determine the optimal initial internal clearance and initial preload required for operation. When using a duplex angular contact ball bearing on the main spindle of a machine tool, the preload is determined by considering the type, main spindle configuration, lubrication system, drive system, intended functions, and other factors. However, preload can also be generalized by the $d_m n$ value ($d_m n$: pitch circle diameter across rolling elements [mm] multiplied by speed [min^{-1}]), as shown below:

$d_m n \leqq 0.5\times10^6$ ……………..Normal preload (GN)
$0.5\times10^6 < d_m n \leqq 0.65\times10^6$ …Light preload (GL)
$d_m n > 0.65\times10^6$ ……………..0 to positive clearance

For detailed information, contact **NTN** Engineering.

Table 9.4 Radial internal clearance of duplex angular contact ball bearings

Unit: μm

Nominal bore diameter *d* mm		C1		C2		CN (normal)	
over	incl.	min	max	min	max	min	max
–	10	3	8	6	12	8	15
10	18	3	8	6	12	8	15
18	30	3	10	6	12	10	20
30	50	3	10	8	14	14	25
50	80	3	11	11	17	17	32
80	100	3	13	13	22	22	40
100	120	3	15	15	30	30	50
120	150	3	16	16	33	35	55
150	180	3	18	18	35	35	60
180	200	3	20	20	40	40	65

For duplex angular contact ball bearings, **NTN** recommends the initial radial clearances and standard preloads shown in **Tables 9.4** through **9.21**. Select the optimal radial internal clearance and initial preload for your application. When ordering a duplex angular ball bearing, please specify the desired preload and clearance. If these are not specified in the order, we will ship a bearing with standard clearance. However, some product types do not have a standard clearance. In this case, we will inform you of the available clearances.

■Standard preloads of angular contact ball bearings (DB and DF arrangements)

⑥ Recommended fit for angular contact ball bearings

If the $d_m n$ value is in the range of $d_m n \leqq 0.75 \times 10^6$ (d_m : pitch circle diameter across rolling elements [mm], n: speed [min^{-1}]), the fit values shown in **Tables 9.22** and **9.23** are recommended to ensure high accuracies of precision bearings.

If the $d_m n$ value is in the range of $d_m n > 0.75 \times 10^6$, it is necessary to consider expansion of inner ring caused by centrifugal force. In this case, contact **NTN** Engineering for the recommended fit. As for the fit of the outer ring with the housing, consider the influence of the ambient temperature (such as heat buildup on a built-in motor or the cooling effect of jacket). For technical assistance, contact **NTN** Engineering.

Table 9.22 Shaft fit

Unit: μm

Nominal bore diameter *d* mm Over	Incl.	Fit of inner ring with shaft
2.5	10	0~2T
10	18	0~2T
18	30	0~2T
30	50	0~3T
50	80	1T~4T
80	120	1T~5T
120	180	2T~7T
180	250	2T~8T

Notes:
1. The mean value should be the target value.
2. If the dmn value of the high-speed machine is in the range of $d_m n > 0.75 \times 10^6$, it is necessary to increase the amount of interference In this case, contact **NTN** Engineering for technical assistance.

T: Tight (Interference) Fit

Table 9.23 Housing fit

Unit: μm

Nominal outside diameter *D* mm		Fit of outer ring with housing	
Over	Incl.	Bearing on fixed side	Bearing on free side
10	50	2L~ 5L	6L~10L
50	80	3L~ 7L	6L~12L
80	120	4L~ 9L	8L~13L
120	150	5L~11L	10L~16L
150	180	6L~13L	11L~17L
180	250	7L~15L	13L~20L
250	315	8L~17L	15L~23L

Notes:
1. The mean value should be the target value.
2. If the $d_m n$ value is in the range of $d_m n > 1.0 \times 10^6$, spacer width and bearing arrangement, it is necessary to increase the amount of interference.
   In this case, contact **NTN** Engineering for technical assistance.

L: Loose fit

⑦ Duplex angular contact ball bearings

Duplex angular contact ball bearings can be combined in rows of two, three or four bearings to accommodate required specifications.

The back-to-back duplex (DB) arrangement and the face-to-face duplex (DF) arrangement allow for the application of both radial loads and axial loads in both directions. The DB arrangement has a wide space between load points and can handle large moment loads. For this reason, this type of duplex arrangement is preferable for use on the main spindles of machine tools.

The DF arrangement cannot handle large moment loads, but its allowable inclination angle is greater than that of the DB arrangement. The tandem duplex (DT) arrangement can handle both a radial load and large axial load, but this bearing can take the axial load in one direction only. The 4-row duplex (type DTBT) arrangement ensures high rigidity in the radial and axial directions and accommodates high-speed operation. For this reason, this type of duplex bearing is commonly used for the main spindles of machining centers.

Each duplex angular contact ball bearing is manufactured as a set to enable adjustment of the preload and clearance. For this reason, combine only duplex bearings of the same product number.

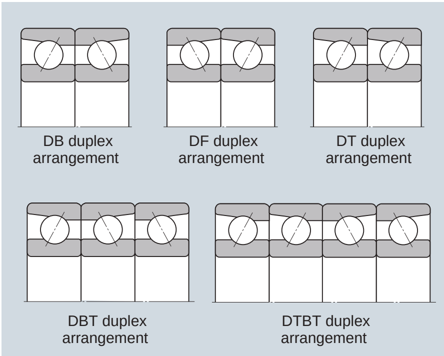

Fig. 9.10

⑧ Duplex arrangement codes for angular contact ball bearings

Each duplex ball bearing has a product number and duplex arrangement code etched on its side face. On angular contact ball bearing sets of three or more, each matching bearing has a "<" mark on its outside surface. Be sure to align the "<" mark when assembling the bearings.

Note that duplex angular contact ball bearing types DB and DF do not have the "<" mark. To match them, align the duplex arrangement codes.

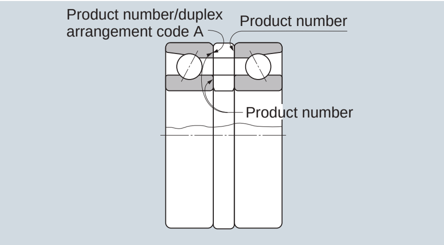

Fig. 9.11

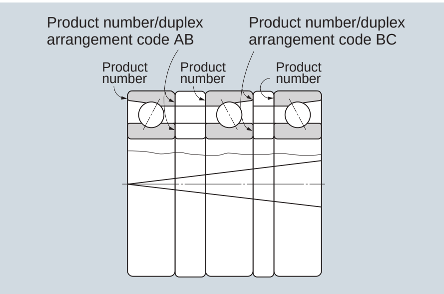

Fig. 9.12

⑨ Flush grinding and universal matching

Angular contact ball bearings are often combined for a special purpose. Face-to-face duplex (DF) arrangement, back-to-back duplex (DB) arrangement and tandem duplex (DT) arrangement may be combined in rows of two or more. When combining many bearings, it is important to control the accuracies of the bearings and to align their face heights in a common plane.

■Flush grinding

"Flush grinding" is a finishing technique in which the front and back faces of the inner and outer rings are aligned with each other to eliminate differences in face height (**Fig. 9.13**). Such alignment can ensure the specified clearance and preload for DF, DB, and DT sets, but it is possible only if the combined bearings have the same clearance/preload symbols. The flush grinding technique is employed for standard BNT series, 0 series, and 2 series bearings designed for main spindles of machine tools, and for 2A-BST thrust angular contact ball bearings designed to support ballscrews.

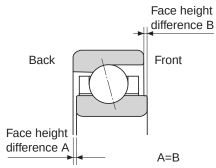

Fig. 9.13 Flush grinding

Note: The flush grinding technique is also adopted for other types of angular contact ball bearings. When ordering a bearing, append "G" to the product number to specify the flush ground type. **Example: 7010UC G/GNP4**

■Universal Matching

In addition to the flush grinding technique, universal matching is employed for duplex angular contact ball bearings. Universal matching controls the bearing-to-bearing dimensional differences in the bore and outside diameters.

NTN can control the bearing-to-bearing difference in the bore and outside diameters to no more than one-third the tolerance (a minimum of 2 μm). Universal matching is adopted for duplex angular contact ball bearings of JIS class 5 or better. When ordering a bearing, specify the desired number of duplex bearings to be used in combination ("D2" for DB, DF or DT; and "D3" for DBT, DFT or DTT). Alternately, indicate the basic combination and specify universal matching.

If two duplex bearings are combined, "D2" is appended to the product number.

Example: 7010UC G D2/GNP4

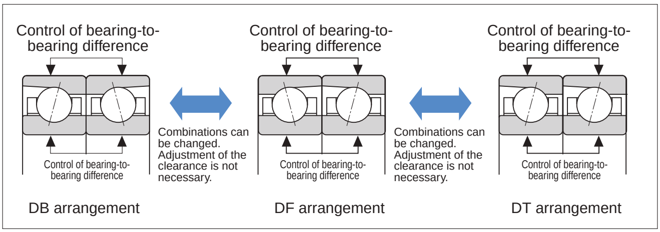

Fig. 9.14 Universal matching

⑩ Angular contact ball bearings with ceramic balls

Recently, the main spindles of machining centers, NC machines and other machine tools have been required to operate at much higher speeds. Bearings for main spindles therefore must meet the requirements of high speed and rigidity as well as accuracy. To meet such requirements, many of our customers want the rolling element made of ceramic material. The features of angular contact ball bearings with ceramic balls are described below.

■Limited temperature rise and ultra-high speeds

The specific gravity of ceramic material is one-half that of bearing steel. In addition, the ball diameter of 5S-HSE type is smaller than that of the standard 70 type. For this reason, use of ceramic balls greatly reduces the influence of centrifugal force (ball sliding and spinning caused by gyratory moment).

As a result, these angular contact ball bearings inhibit temperature buildup and ensure ultra-high speed.

■High bearing rigidity for high accuracy of manufactured products

The Young's modulus of ceramic material is approximately 1.5 times that of bearing steel. The rigidity of these angular contact ball bearings is therefore greatly increased.

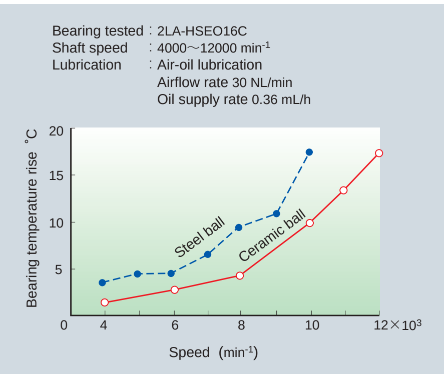

Fig. 9.15 Comparison of temperature rise between bearings with ceramic balls and those with steel balls

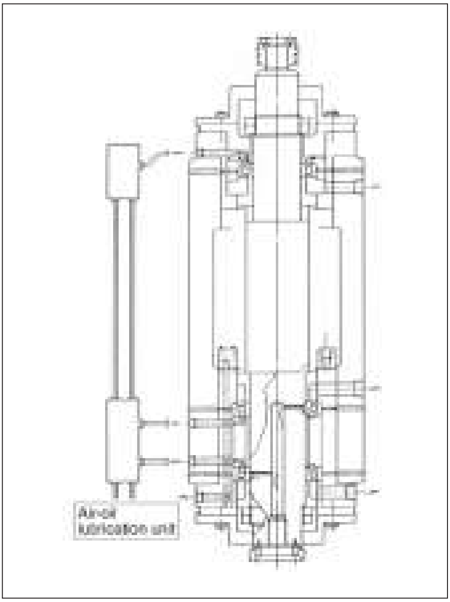

Fig. 9.16 Test rig for measuring temperature rise

Table 9.24 Comparison of physical properties between ceramic and steel balls

Item	Ceramic (Si_3N_4)	Bearing steel (SUJ2)
Density (g/cm³)	3.304	7.8
Young's modulus (GPa)	315	210
Poisson's ratio	0.25	0.3
Thermal expansion ($\times 10^{-6}$/°C)	3.2	12.5
Thermal conductivity ratio (Cal/cm·s·°C)	0.07	0.1～0.12

⑪ Operating life of bearings with ceramic balls

Shaft speed : 2000 min^{-1}
Lubrication : Class 1 turbine oil (VG56), circulating lubrication

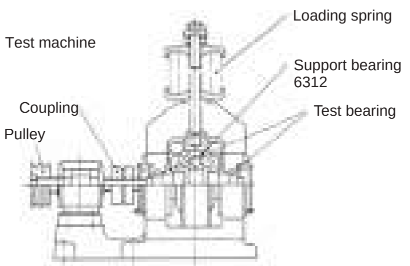

Fig. 9.17 Radial load-type bearing life test machine

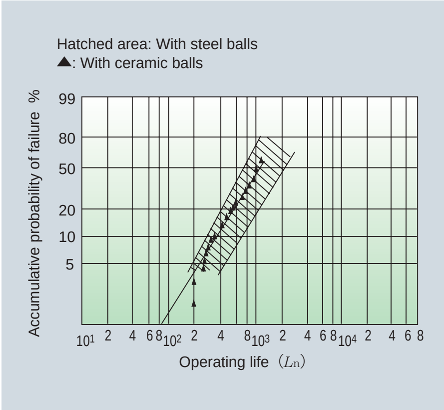

Fig. 9.18 Operating life of ball bearing with ceramic balls

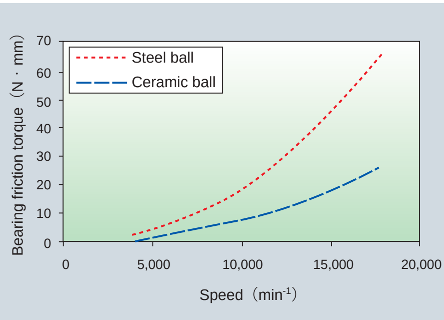

Fig. 9.19 Frictional torque

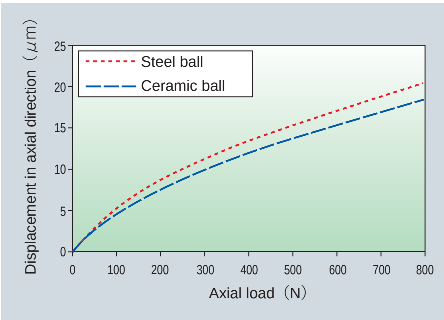

Fig. 9.20 Displacement in axial direction

⑫ Recommended lubrication

Angular contact ball bearings are usually used with grease lubrication or air-oil lubrication. Recommended lubrication specifications are described below.

■Grease lubrication

● **Recommended brand of grease**

Refer to 7. Lubrication of Bearings, 7-1 Grease lubrication in the Technical Data section.

● **Recommended grease fill**

$d_m n$ value≦0.65×10^6

15% of the capacity shown in the dimension tables

$d_m n$ value＞0.65×10^6

12% of the capacity shown in the dimension tables

● **Recommended grease filling method**

Refer to 6. Handling of Bearings, 6-1 Cleaning of bearings and filling with grease in the Technical Data section.

● **Notes**

Grease-lubricated sealed angular contact ball bearings (79 LLB/70 LLB type, and BNS type bearings) are prefilled with long-life SE-1 grease. Wipe rust preventive oil from the outside of the bearing with a clean cloth.

■Air-oil lubrication

● **Recommended location of nozzle**

Refer to 7. Lubrication of Bearings, 7-2 Air-oil lubrication in the Technical Data section.

● Recommended specifications of nozzle

Nozzle bore dia.: 1 to 1.5 mm

Number of nozzles: One nozzle per bearing, depth of nozzle bore should be four to six times as large as the bore diameter.

● Recommended specifications of air-oil

Oil type: Spindle oil

Viscosity grade: ISO VG from 10 to 32 (32 is preferable)

Table. 9.25 Air and oil amount

Bearing type	$d_m n$ value ($\times10^6$)		Oil valume per shot	Lubrication intervals	Oil consumption	Recommended air consumption
	Over	Incl.	mL	min	mL/h	*NL/min
78C,79U,70U, 72C		～ 1.0	0.03	8	0.23	20～40
HSE9, HSE0	1.0	～ 1.5		5	0.36	
HSF	1.5	～ 2.6		2	0.90	
HSL		～ 2.6		10	0.18	
HSFL						
HSEW		～ 2.2				

*N ℓ /min (Normal liter/minute) ... N ℓ means the volume of air at 0˚C and 1 atmosphere.

Note) The amount of oil and air needs to be adjusted to suit the spindle structure or the differences in discharge channels.
Set the amounts after checking with actual machine tests.

⑬ ULTAGE Standard angular contact ball bearings 79U and 70U types

ULTAGE 79U and 70U series bearings were developed from standard angular contact ball bearings (79 and 70). Optimized internal design and adoption of a new resin cage allows high-speed operation and ensures high rigidity.

■Features

1. Optimized internal design enables high-speed operation and high rigidity.
2. A new resin cage enables improvement in grease retention for grease lubrication and enhanced performance in feeding and discharge of oil for air-oil lubrication.
3. Bearings are available with either steel or ceramic balls.
4. Three contact angles (15˚, 20˚, and 30˚) are available to handle a wide range of applications.

■Bearing specifications

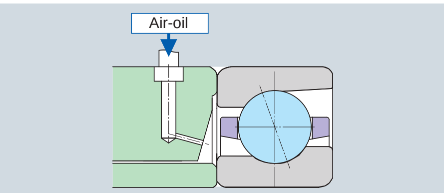

Fig. 9.21 79U and 70U types

Photo 9.1 New resin cage

■High-speed operation

Optimized internal design and adoption of a new resin cage enable stable operation at $d_m n$ value 0.95×10⁶, with grease lubrication.

【Test conditions】

Test Bearing	7010UCDB (φ50×φ80×16)
Shaft speed	0~15000 min⁻¹
Preload after assembled	200 N (Fixed position preloading)
Grease lubrication	NBU15

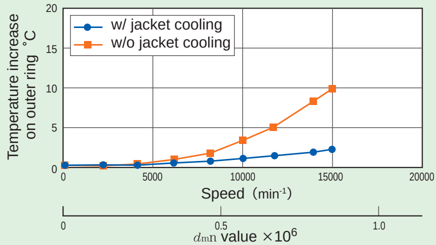

Fig. 9.22 High-speed test with grease lubrication

Stable operation is possible with $d_m n$ value 1.5×10⁶, with air-oil lubrication.

【Test conditions】

Tested Bearing	7010UCDB (φ50×φ80×16)
Speed	0~23000 min⁻¹
Preload after assembled	200 N (Fixed position preloading)
Air-oil lubrication	0.03 mL/shot (oil injection intervals: 5 min, air consumption: 40 NL/min)

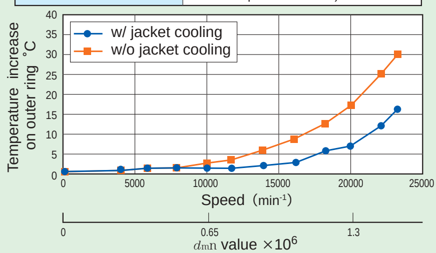

Fig. 9.23 High-speed test with air-oil lubrication

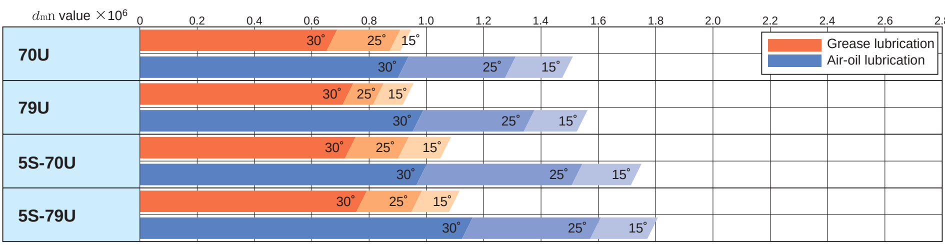
■Permissible speed range



Notes) Permissible speed of each bearing ($d_m n$ value) varies depending on the specifications of the machine on which the bearing is used (motor drive system, cooling system, and construction around the bearing). Consider the optimal choice referring to the above guideline (for two-row arrangement), and then, contact **NTN** Engineering for technical assistance.

⑭ ULTAGE High-speed angular contact ball bearings HSE type

The HSE type employs a special material featuring greatly improved wear resistance and anti-seizure properties as well as a special surface modification technique. Furthermore, thanks to an optimized internal design, this type achieves high speed, high rigidity and high reliability.

■Features

1. Adoption of special materials and a unique internal design improve anti-seizure properties (15 times better than the conventional type) and wear resistance (6 times better than of the conventional type).
2. Optimized internal design enables high-speed operation and high rigidity.
3. Bearings are available with either steel or ceramic balls.
4. Three contact angles (15˚, 20˚, and 25˚) are available to handle a wide range of applications.

■Bearing specification

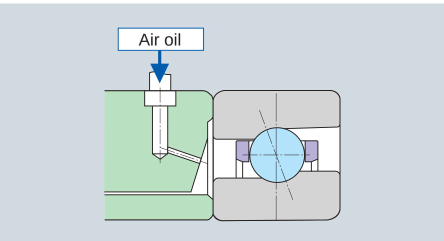


Fig. 9.24 HSE type

Preload and low temperature rise

The 5S-HSE type features high speed and limited temperature increase. Even if its preload is increased after assembly into the spindle, it maintains stable performance at high speeds (**Fig. 9.25**).

【Test condition】

Test bearing	5S-2LA-HSE020 (contact angle 20˚) (φ100×φ150×24×2 rows)
Shaft speed	0～15000 min^{-1}
ubricatio n	Air-oil lubrication
Oil consumption	0.03 mL/shot (Oil shot intervals 5 min)
Air consumption	40NL/min
Outer casing cooling	Provided

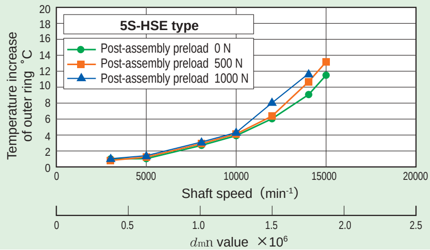

Fig. 9.25 elationship bet een preload and te perature increase

Improved main spindle rigidity

When built into a high-speed main spindle, the preload of the 5S-HSE standard type is maintained, allowing high rigidity (1.9 times greater than a conventional bearing) (**Fig. 9.26**).

【Test condition】

Test bearing	5S-HSB020 (contact angles 15˚and 20˚) 5S-2LA-HSE020 (contact angle 20˚) (φ100×φ150×24×2 rows)	
Post-assembly preload	5S-HSB020	0 N
	5S-HSE020	500 N

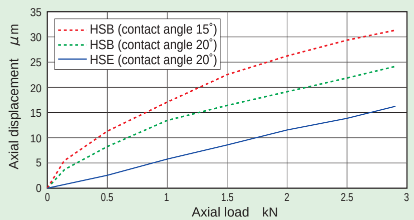

Fig. 9.26 Comparison of rigidity relative to conventional bearing (HSB type) in terms of post-assembly preload

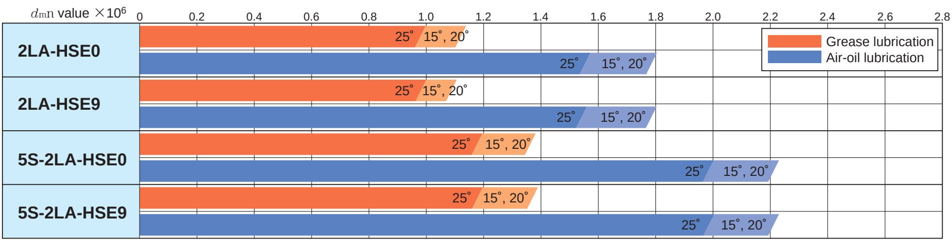
■Permissible speed range



Notes) Permissible speed of each bearing (dmn value) varies depending on the specifications of the machine on which the bearing is used (motor drive system, cooling system, and construction around the bearing). Consider the optimal choice referring to the above guideline (for two-row arrangement) and then contact **NTN** Engineering for technical assistance.

⑮ ULTAGE Super high-speed angular contact ball bearings HSF type

The HSF type realizes further improvement in high-speed running and inhibited temperature rise by adoption of smaller diameter ceramic balls, while retaining features of the HSE type. This type attains d_mn values as high as 2.6×10^6 with fixed pressure preloading.

■Features

1. Adoption of special materials and a unique internal design improve anti-seizure property (15 times better than the conventional type) and wear resistance (6 time better than the conventional type).
2. Optimized internal design enables high-speed operation and high rigidity.
3. Ceramic balls are used.
4. Initial contact angle is set to 25° to accommodate the change in contact angle during super high-speed operation.

■Bearing specification

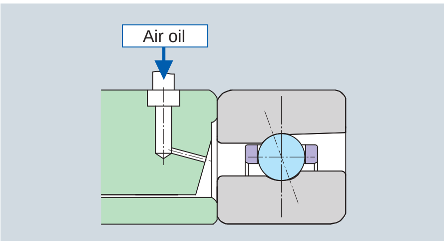


Fig. 9.27 HSF type

■Low temperature rise

Super high-speed 5S-HSF series angular contact ball bearings utilize smaller balls than those of the high-speed HSE series. This reduces heating due to centrifugal force and ensures lower temperature rise. Thus, the 5S-HSF type boasts an approximately 10% reduction in temperature rise as compared to the 5S-HSE type. (**Fig. 9.28**)

【Test condition】

Test bearing	5S-2LA-HSE020 (contact angle 20°) 5S-2LA-HSF020 (contact angle 25°) (φ100×φ150×24×2 rows)
Shaft speed	0～14000 min⁻¹
Lubrication	Air-oil lubrication
Oil consumption	0.03 mL/shot (Oil shot intervals 5 min)
Air consumption	40NL/min
Outer casing cooling	None

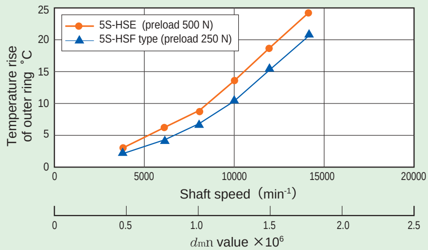

Fig. 9.28 o parison o te perature rise

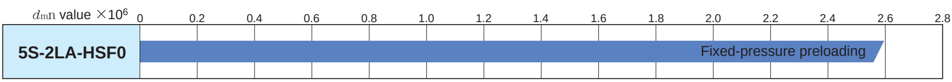
■Permissible speed range



Notes) Permissible speed of each bearing (d_mn value) varies depending on the specifications of the machine on which the bearing is used (motor drive system, cooling system, and construction around the bearing). Consider the optimal choice referring to the above guideline (for two-row arrangement) and contact **NTN** Engineering for technical assistance.

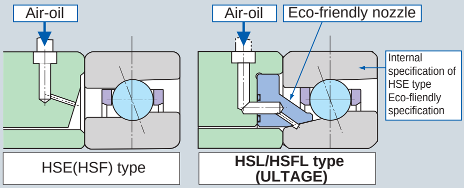
⑯ ULTAGE Eco-friendly air-oil lubricated angular contact ball bearings HSL type HSFL type

The HSL/HSFL type is an advanced variation of the HSE/HSF type, characterized by incorporation of **NTN**'s unique eco-conscious lubrication technology. The HSL type helps decrease oil mist emissions and consumption of air and oil, improving the working environment for machine tool operators and reducing energy consumption.

■Features

1. Adoption of special materials and a unique internal design improve anti-seizure properties (15 times better compared with the conventional type) and wear resistance (6 times better than the conventional type).
2. Bearings are available with either steel or ceramic balls (HSFL is available with ceramic balls only).
3. Adoption of eco-friendly nozzle reduces noise (reduction of 2 to 8 dBA), air consumption (reduction of 50 to 75%) and oil consumption (reduction of 20 to 90%)

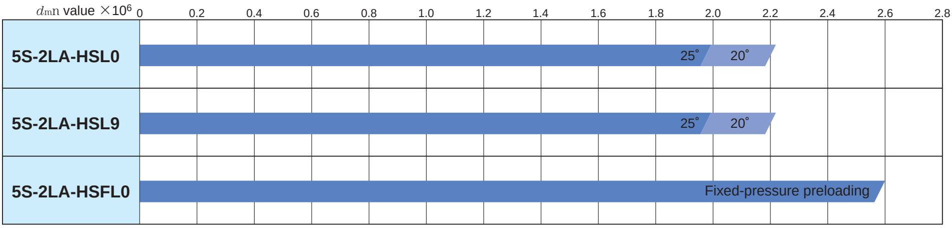
■Bearing specification



NOTE) The HSL/HSFL type is packed together with the spacer with the eco-fliendly nozzle. The bearing type code HSL represents the bearing proper, while a spacer code stands for an eco-conscious nozzle proper or a spacer having a built-in nozzle.
For more details, see "3. Bearing Designation".

Fig. 9.29 HSL and HSFL types

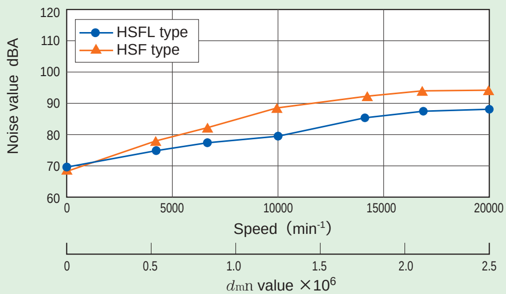
■Permissible speed range



Notes) Permissible speed of each bearing (d_mn value) varies depending on the specifications of the machine on which the bearing is used (motor drive system, cooling system, and construction around the bearing). Consider the optimal choice referring to the above guideline (for two-row arrangement) and contact **NTN** Engineering for technical assistance.

Data 1

In the high-speed region of 10000 min^{-1}, the noise level of the HSL type is 6 dBA to 8 dBA lower than that of the conventional type (HSC type) (**Fig. 9.30**).



【Test conditions】

Test bearing	5S-2LA-HSFL020DB 5S-2LA-HSF020DB (φ100×φ150×24×2 rows)
Shaft speed	20000 min^{-1}
Preload	2.5 kN (constant pressure preloading)

Fig. 9.30 Comparison of noise levels

Data 2

For 5S-HSFL typebearings, the temperature of the outer rings remains stable even with an air consumption as low as 10 N ℓ /min (50 to 25% of the recommended air consumption for standard bearings) at a speed of 21000 min^{-1} ($d_m n$ value 2.6×10^6) (**Fig. 9.31**).

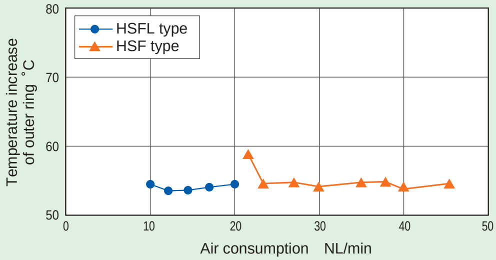


Fig. 9.31 Relationship between air consumption and temperature increase

【Test conditions】

Test bearing	5S-2LA-HSFL020DB 5S-2LA-HSF020DB (φ100×φ150×24×2 rows)
Shaft speed	21000 min^{-1}
Preload	2.5 kN (constant pressure preloading)
Oil consumption	0.03 mL/shot (oil shot intervals, 5 min)

Data 3

The 5S-HSFL type bearings can operate at 21000 min^{-1} ($d_m n$ value 2.6×10^6) with oil shot intervals of 21 min (reduction of 20 to 90% as compared with the recommended oil consumption for standard bearings) (**Fig. 9.32**).

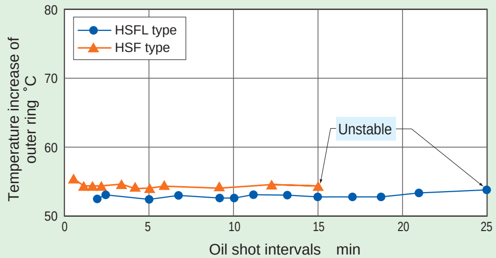

Fig. 9.32 Relationship between oil shot intervals and temperature increase

【Test conditions】

Test bearing	5S-2LA-HSFL020DB 5S-2LA-HSF020DB (φ100×φ150×24×2 rows)
Shaft speed	21000 min^{-1}
Preload	2.5 kN (constant pressure preloading)
Oil consumption	0.03 mL/shot
Air consumption	12.5 NL/min (HSFL) 30 NL/min (HSF)

Data 4

5S-HSL type bearings can reliably run at a speed of 19000 min^{-1} (fixed position preloading) (**Fig. 9.33**) with both decrease air and oil consumption.

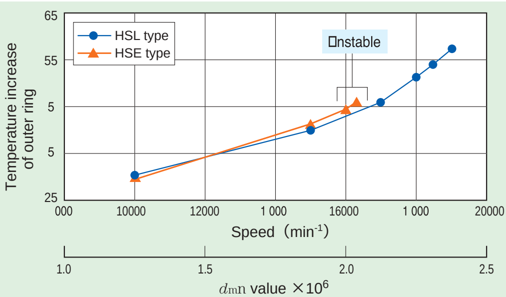

Fig. 9.33 High-speed test results (fixed position preloading)

【Test conditions】

Test bearing	5S-2LA-HSL020DB 5S-2LA-HSE020DB (φ100×φ150×24×2 rows)
Shaft speed	10000～19000 min^{-1}
Preload	After assembly, 0 (fixed position preloading)
Oil consumption	0.03 mL/shot (oil shot intervals, 10 min)
Air consumption	10 NL/min (HSL) 30 NL/min (HSE)

⑰ ULTAGE Air-oil lubricated high-speed angular ball bearings with re-lubricating hole on the outer ring – HSEW Type

HSEW type is an air-oil lubricated high-speed angular ball bearing equipped with re-lubricating holes on the outer ring of the HSE type. Because there is no requirement for providing a nozzle hole on the spacer, the spacer width can be kept short, contributing to the more compact main spindle and improvement of spindle rigidity due to the placement of the bearings on the tool tip side.

In addition, lubrication reliability is increased due to the direct lubrication from the outer ring, enabling the reduction of air consumption and the supplied oil amount.

■Bearing specification

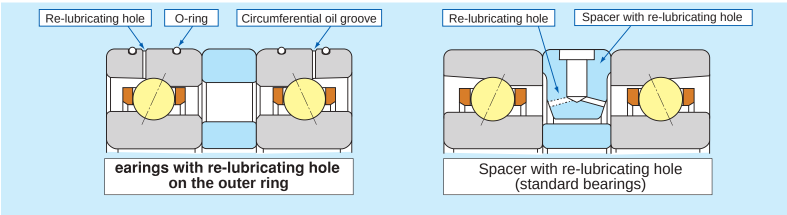

Fig. 9.34 HSEW Type

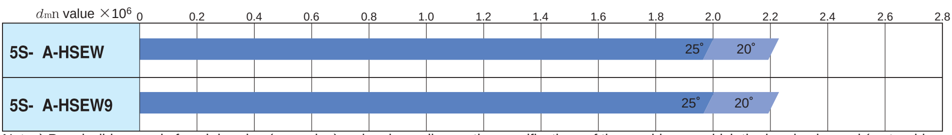
■Features

1. Compact main spindle design is possible due to the shorter spacer
2. Higher re-lubricating efficiency by the direct lubrication from the outer ring
3. Reduced noise level due to the air reduction effect

■Permissible speed range



Notes) Permissible speed of each bearing (d_mn value) varies depending on the specifications of the machine on which the bearing is used (motor drive system, cooling system, and construction around the bearing). Consider the optimal choice referring to the above guideline (for two-row arrangement) and contact **NTN** Engineering for technical assistance.

■About chamfering of re-lubricating hole on the housing

Ensure to provide chamfering on the re-lubricating hole of the housing to avoid damage of outer O-ring when the HSEW type is inserted into the housing (**Fig. 9.35**).

We recommend that chamfering is only applied to the hole.

■About phases of re-lubricating hole on the housing and re-lubricating hole on the outer ring

For producing the air reduction effect, be sure to stagger the position of re-lubricating hole on the housing and re-lubricating hole on the outer ring.

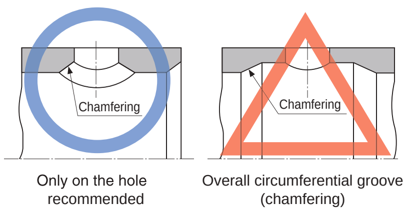


Fig. 9.35 Chamfering of re-lubricating hole on the housing

■Data 1

For the HSEW type bearings, the temperature of the outer rings remains stable even with an air consumption as low as 20 Nℓ/min (1/2 of the recommended air consumption for standard bearings) at a speed of 18,000 min^{-1} ($d_m n$ value 2.25×10^6) (**Fig. 9.36**).

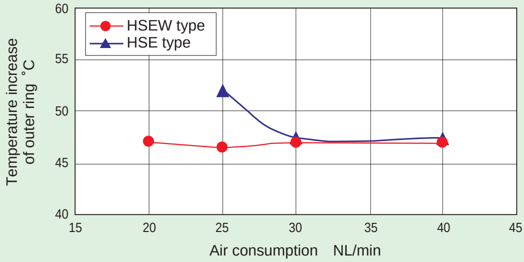

Fig. 9.36 Relationship between air consumption and temperature increase

【Test conditions】

Test bearing	5S-2LA-HSEW020 5S-2LA-HSE020 (φ100×φ150×24×2 rows)
Shaft speed	18000 min^{-1}
Preload	98 N after assembled (Fixed position preloading)
Oil consumption	0.03 mL/shot (oil shot intervals) HSEW : 10 min, HSE : 5 min

■Data 2

The HSEW type bearings can operate at 18,000 min^{-1} ($d_m n$ value 2.25×10^6) with an oil shot interval of 20 min (1/4 of the recommended oil consumption for standard bearings) (**Fig. 9.37**).

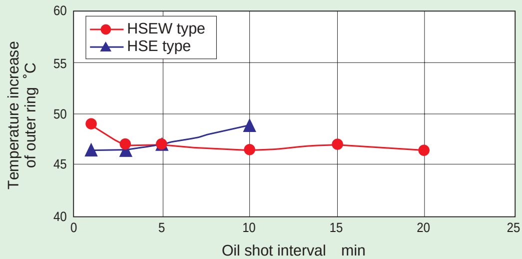

Fig. 9.37 Relationship between oil shot interval and temperature increase

【Test conditions】

Test bearing	5S-2LA-HSEW020 5S-2LA-HSE020 (φ100×φ150×24×2 rows)
Shaft speed	18000 min^{-1}
Preload	98 N after assembled (Fixed position preloading)
Air consumption	HSEW : 20NL/min HSE : 40NL/min
Oil consumption	0.03ml/shot

■Data 3

The HSEW type has achieved reduced noise level compared with the HSE type (**Fig. 9.38**).

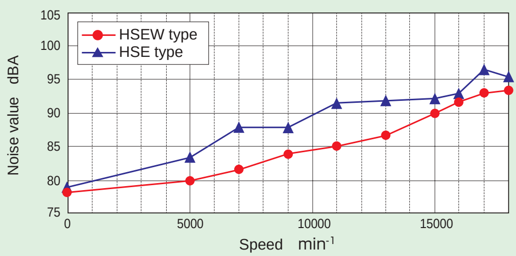

Fig. 9.38 Comparison of noise levels

【Test conditions】

Test bearing	5S-2LA-HSEW020 5S-2LA-HSE020 (φ100×φ150×24×2 rows)
Shaft speed	18000 min^{-1}
Preload	98 N after assembled (Fixed position preloading)
Air consumption	HSEW : 20NL/min HSE : 40NL/min
Oil consumption	0.03 mL/shot (oil shot intervals) HSEW : 10 min, HSE : 5 min

⑱ ULTAGE Grease-lubricated sealed standard angular contact ball bearings 79LLB and 70LLB, 5S-79LLB and 5S-70LLB types

The 79LLB and 70LLB types are grease-lubricated, eco-friendly bearings that can achieve stable high-speed operation with limited temperature rise.
They can allow, longer service life and preservation of healthy working environment for rotating tools with shaft diameters less than 50 mm.

■Features

1. Internal design is optimized for high-speed operation and limited temperature rise.
2. Longer grease life due to adoption of special grease and non-contact seals for grease retention.
3. Contact angles of 15˚ and 25˚ are available.
4. The standard types meet special precision P42 requirements (dimensional precision JIS P4 and running accuracy JIS P2).
5. Seals of different colors are used for front (black) and back (orange) sides. Bearing configuration can be easily identified by color.
6. Available with either steel or ceramic balls.

■Bearing specifications

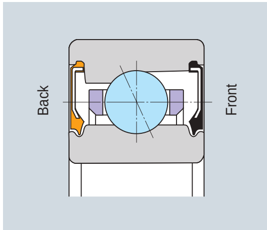

Fig. 9.39
79LLB and 70LLB types

■Simplified main spindle configuration

Due to the optimized internal structure, the 79LLB and 70LLB types can reliably run at a higher speed with grease lubrication. The grease lubricating system is virtually free from oil mist emission, and contributes to a simpler main spindle structure, reduction in environmental impact and decrease in cost. (**Fig. 9.40**)

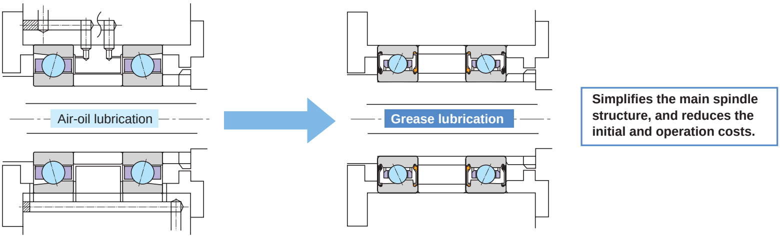

Fig. 9.40 Modification of lubrication system (air-oil lubrication to grease lubrication)

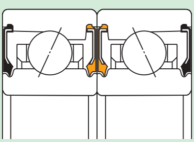
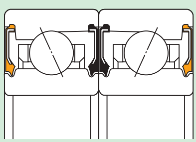
■Easier handling with 79LLB and 70LLB types

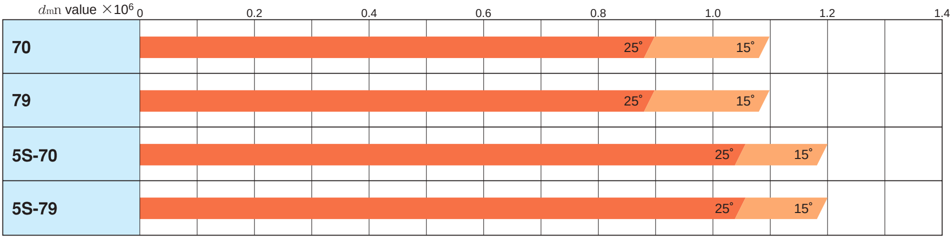
The 79LLB and 70LLB types are prefilled with grease. They can be readily used after only wiping away rust preventive oil. Seals of different colors are used for the front and back sides of the bearing. Black seals are used for the front sides and orange seals are used for the back sides, so configurations are readily identified by colors. (**Table 9.26**)

Table 9.26 Bearing Combinations and Seal Colors

DB set (back faces in combination)	DF set (front faces in combination)
Orange seal ＋ Orange seal	Black seal ＋ Black seal
 	 




■Permissible speed range



Notes) Permissible speed of each bearing (dmn value) varies depending on the specifications of the machine on which the bearing is used (motor drive s stem cooling s stem and construction around the bearing). Consider the optimal choice referring to the above guideline (for two-row arrangement) and contact **NTN** ngineering for technical assistance.

■High-speed test

Optimization of the internal design promotes stable operation of dmn value 1.1×10⁶. (**Figs.9.41** and **9.42**)

⑲ ULTAGE Grease-lubricated sealed angular contact ball bearings BNS LLB and 5S-2LA-BNS LLB types

By the optimized material and internal structure, BNS LLB type bearings have excellent performance at higher speeds. This helps to reduce pollution and cost.

■Features

1. Adoption of special materials and unique internal design improve anti-seizure properties (15 times better than the conventional type) and wear resistance (6 times better than the conventional type).
2. Optimized internal design enables high-speed operation and high rigidity.
3. Available with either steel or ceramic balls.
4. Adoption of grease pockets, special grease, and non-contact seals improves service life of the grease.

■Bearing specification

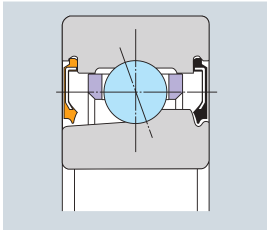

Fig. 9.43 BNS LLB type

■Simplified main spindle configuration

BNS LLB type bearings can reliably operate at a higher speed with grease lubrication. The grease lubrication system is virtually free from oil mist emission can simplify the main spindle structure, reduce pollution and decrease cost **(Fig. 9.44**).

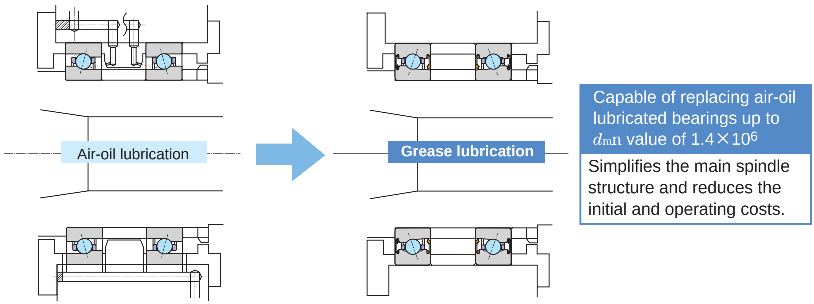

Fig. 9.44 Modification of lubrication system (air-oil lubrication to grease lubrication)

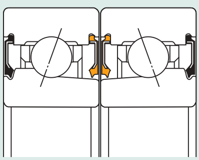
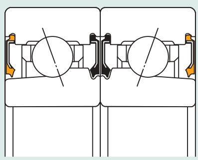
■Easier handling with BNS LLB type

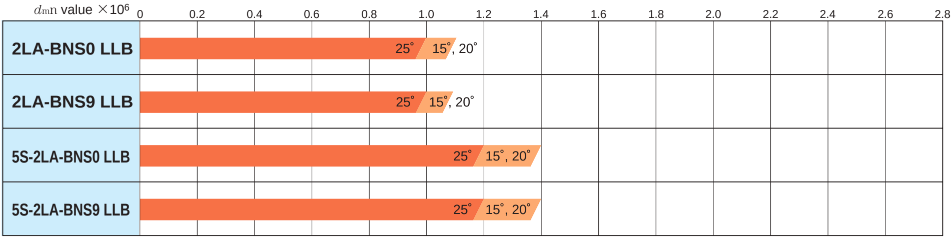
The BNS LLB type has been packed with grease in advance. They can be used after wiping away rust preventive oil. Seals in different colors are used for the front and back sides of the bearings. Black seals are used for the front sides and orange seals are used for the back sides, so configurations can be easily identified by color. (**Table 9.27**)

Table 9.27 Bearing Combinations and Seal Colors

DB set (back faces in combination)	DF set (front faces in combination)
Orange seal + Orange seal	Black seal + Black seal
 	 




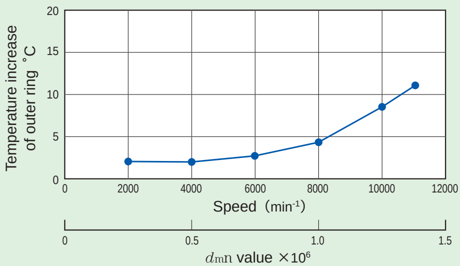
■Permissible speed range



Notes) Permissible speed of each bearing ($d_{m}n$ value) varies depending on the specifications of the machine on which the bearing is used (motor drive system, cooling system, and construction around the bearing). Consider the optimal choice referring to the above guideline (for two-row arrangement) and contact **NTN** Engineering for technical assistance.

Temperature increase

5S-2LA-BNS LLB type bearings exhibit stable temperature increase up to a $d_{m}n$ value of 1.4×10⁶ (**Fig. 9.45**).



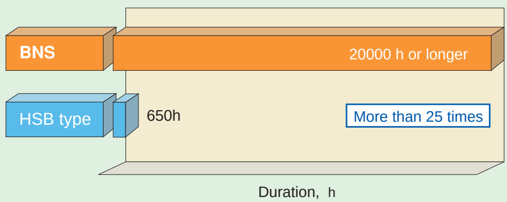
【Test conditions】

Test bearing	5S-2LA-BNS020 LLBDB (φ100×φ150×24×2 rows)
Shaft speed	11000 min⁻¹
Outer casing cooling	Provided

Fig. 9.45 High-speed test results

Durability test

As a result of optimized design (such as grease reservoir) and special grease, 5S-2LA-BNS LLB type bearing have successfully achieved continuous operation in excess of 20,000 hours at a $d_{m}n$ value of 1.4×10⁶ (**Fig. 9.46**).



【Test conditions】

Main Spindle Bearings

10. Cylindrical Roller Bearings CONTENTS

10. Cylindrical Roller Bearings

In a cylindrical roller bearing, the rollers and raceways are in line contact. Consequently this type of bearing can support a larger radial load than a point-contact ball bearing. Also, its design is suitable for high-speed operation.

A cylindrical roller bearing used for the main spindle of a machine tool can have either a double- or single-row configuration, and certain variants have a tapered bore so the radial internal clearance can be adjusted.

① Double-row cylindrical roller bearings

Double-row cylindrical roller bearings are available in two types, NN and NNU, and two series, 30 and 49. The rollers in the NN type bearing are guided by the ribs of the inner ring. The rollers in the NNU type bearing are guided by the ribs of the outer ring. Bearings are available with either a tapered bore (which allows adjustment of radial internal clearance of bearing) or a standard cylindrical bore.

The bearings come in two types, standard type and high-speed HS type. Standard cage is machined brass.

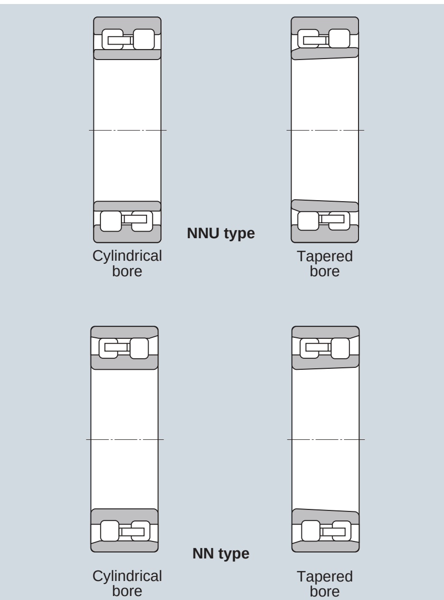

Fig. 10.1

② Single-row cylindrical roller bearings

Single-row cylindrical roller bearings are available in two types, high-speed N10HS type and ultra high-speed N10HSRT6 type. The N10HS type bearings have high-strength machined brass cages, while the N10HSR type bearings have special molded resin cages, which can be used for both grease lubrication and air-oil lubrication. The eco-friendly N10HSLT6 type is a variation from the high-speed N10HSRT6 type bearing and can be used with air-oil lubrication only.

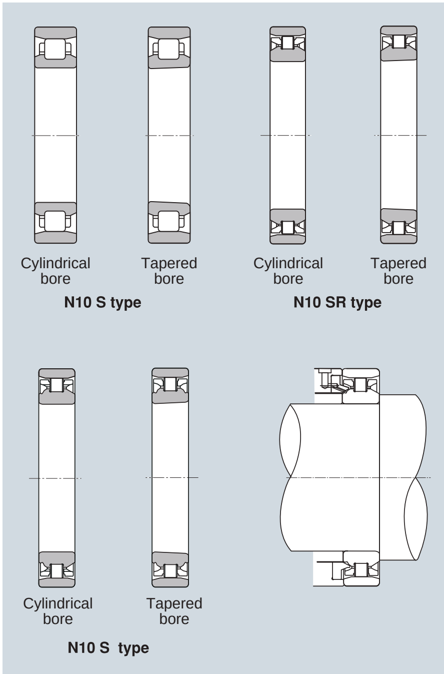

Fig. 10.2

- **Internal modification code**

④ Accuracy of tapered bore

NTN specifies the accuracies of tapered bores conforming with JIS Classes 4 and 2 as shown below. Poor accuracies of the tapered bore lead to misalignment of the inner ring, causing poor performance, premature seizure and flaking. Use of a taper gauge is recommended for higher accuracy of the main spindle. Refer to "6 Handling of Bearings, ⑧ Tapered bore cylindrical roller bearing and main spindle taper angle" in the Technical Data section for more information on taper angle.

Table 10.1 Tolerance of taper-bored bearings

⑥ Radial internal clearance of cylindrical roller bearings

■Non-interchangeable radial internal clearance

Two types of radial internal clearance are available: non-interchangeable radial internal clearance for which the combination of outer ring and inner ring cannot be changed; and interchangeable radial internal clearance that allows for different outer ring and inner ring combinations. The clearances listed are common to both double-row and the single-row cylindrical roller bearings. For machine components including high-precision machine tool main spindle, bearings with non-interchangeable radial internal clearance and a small clearance range are used. If a double-row tapered bore bearing is used and the desired mounted internal clearance is close to zero, use of clearance in the range between C9NA and C1NA is recommended. Cylindrical bore bearings with non-interchangeable radial internal clearance are also available. For details, contact **NTN** Engineering.

■Adjustment of clearance in tapered bore bearings

Mounted internal clearance of a tapered bore bearing can be adjusted by controlling the drive-up of the tapered bore onto the shaft. Two types of adjusting methods area available: repeated adjustment of spacer width and adjustment with using a mounted internal clearance gauge. The clearance gauge is convenient for mass-production. Refer to "6. Handling of Bearings, ⑦ Clearance adjustment for cylindrical roller bearing, measurement with mounted internal clearance gage" in the Technical Data section.

⑦ Recommended fit of high-precision cylindrical roller bearings

In order to maintain the high precision of the bearing at $d_m n$ values less than 0.75×10[6] the fits listed in **Tables 10.7** and **10.8** are recommended ($d_m n$: pitch circle diameter across rolling elements [mm] multiplied by speed [min^{-1}]).

When the $d_m n$ value is larger than 0.75×10[6] ($d_m n$ value≧0.75×10[6]), consult **NTN** Engineering about the recommended fit. Expansion of the inner ring due to centrifugal force must be considered when determining shaft fit.

Table 10.7 Fit with shaft

Note 1: Target the median value.
T: Tight (Interference) fit

■Fit of tapered bore bearings

When fitting a tapered bore bearing onto a shaft, carefully and thoroughly adjust the fit of the tapered bore to the shaft to maintain high precision of the bearing.

For details of taper angle adjustment refer to "6. Handling of Bearings, ⑧ Cylindrical roller bearing and main spindle taper angle" in the Technical Data section.

⑧ Recommended lubrication specifications

Cylindrical roller bearings are usually used with grease lubrication or air-oil lubrication. Recommended lubrication specifications are described below.

■Grease lubrication

● Recommended brand of grease

Refer to "7. Lubrication of Bearings, ① Grease lubrication" in the Technical Data section.

● Recommended grease fill

10% of the internal free space shown in the dimension tables

● Recommended grease packing method

Refer to "6. Handling of Bearings, ① Cleaning and filling with grease" in the Technical Data section.

■Air-oil lubrication

● Recommended location of nozzle

Refer to "7. Lubrication of Bearings, ② Air-oil lubrication" in the Technical Data section.

● Recommended specifications of nozzle

Nozzle bore diameter.: From 1 to 1.5 mm
Number of nozzles: One nozzle for each bearing, depth of nozzle bore should be four to six times the nozzle diameter.

● Recommended specifications of air-oil

Oil type: Spindle oil
Viscosity grade: ISO VG from 10 to 32 (32 is

⑨ ULTAGE Ultra high speed double row cylindrical roller bearings NN30HSRT6 type

NN30HSRT6 ultra high speed double row cylindrical roller bearings have higher operating speeds with the same level of rigidity and capacity as the conventional series.

Features

1. Optimized internal design to realize high speed and low temperature rise.
2. Molded PEEK cage is used for high speed under grease & air-oil lubrication and grease life.

■Bearing design

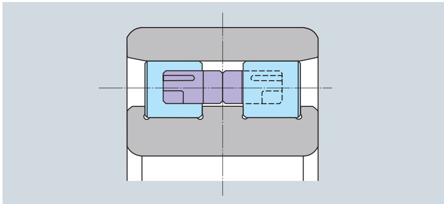

Fig. 10.4 NN30HSRT6 type

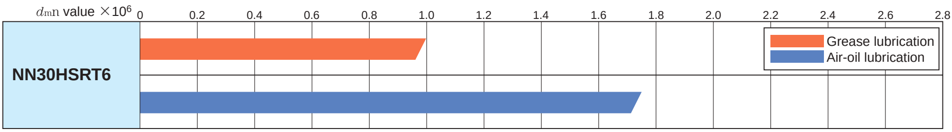
■Permissible speed range



Notes) Permissible speed of each bearing (*d*mn value) varies depending on the specifications of the machine for which the bearing is used (motor drive system, cooling system, and construction around the bearing). Consider the optimal choice referring to the above guideline and contact **NTN**.

■Cage design

Cage is made of PEEK which is very light and strong. (**Photo 10.1**)

By using a proven cage design made of PEEK material, less deformation of the cage is seen due to centrifugal force. As a result, the high speed operation of the bearing is improved. The grease life of the bearing is improved by including a pocket for grease in the cage.

Photo 10.1 PEEK cage

■High speed test

$d_m n$ value of 1.0×10^6 under grease lubrication and 1.75×10^6 under air-oil lubrication are realized by the optimized internal design. (**Fig 10.5, 10.6**)

【Test conditions】

Fig. 10.7 Comparison of grease life

⑩ ULTAGE Ultra high-speed single row cylindrical roller bearings N10HSRT6 type

N10HSRT6 type cylindrical roller bearings have been designed for high-speed operation.

Features

1. Optimized internal design allows high speed operation and limits temperature increase.
2. Special resin cage is suitable for high-speed operation.

■Bearing specification

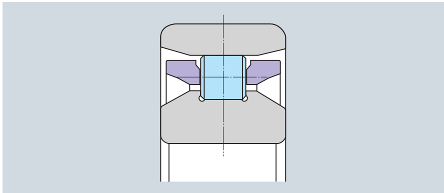

Fig. 10.8 N10HSRT6 type

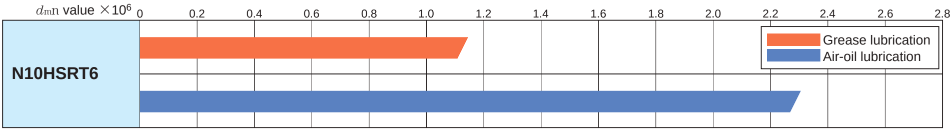
■Permissible speed range



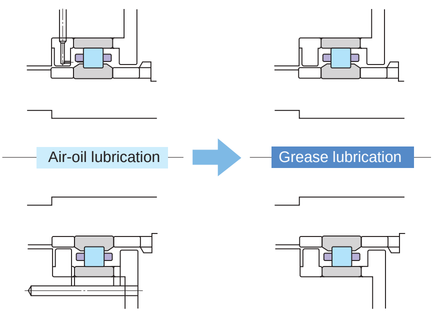
Notes) Permissible speed of each bearing (d_mn value) varies depending on the specifications of the machine for which the bearing is used (motor drive system, cooling system, and construction around the bearing). Consider the optimal choice referring to the above guideline and contact **NTN**.

■Simplified main spindle configuration / adoption of simplified lubrication system

Due to an optimized internal structure, the N10HSR type bearings can reliably run at a higher speed with grease lubrication. The grease lubrication system greatly contributes to reduction in pollution of the surrounding environments by virtually eliminating oil mist (**Fig. 10.9**).

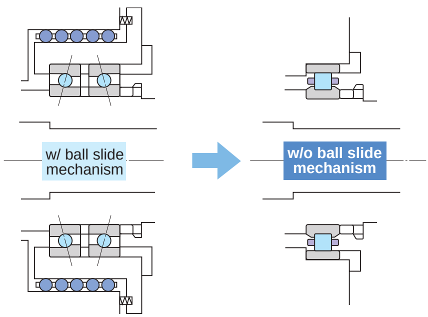
■Simplified main spindle configuration / simplified main spindle rear structure

N10HSR (N10HSL) type high-speed cylindrical roller bearings can replace angular contact ball bearings on the rear side of the main spindle. This arrangement decreases the number of bearing rows (two rows to one row) and eliminates the ball slide mechanism, greatly contributing to simplification of the rear structure (**Fig. 10.10**).



Capable of replacing air-oil lubricated bearings up to d_mn value of 1.15×10^6.

Fig. 10.9 Modification of lubrication system



Capable of replacing angular contact ball bearings up to d_mn value of 2.3×10^6 [air-oil lubrication] or 1.15×10^6 [grease lubrication].

Fig. 10.10 Simplified main spindle rear structure

High-speed operation test with grease lubrication

Due to an optimized internal design, the N10HSR type is capable of high-speed operation with $d_m n$ value of 1.15×10⁶ [grease lubrication] or 2.3×10⁶ [air-oil lubrication] (**Figs. 10.11, 10.12, 10.13, 10.14**).

Lubrication	Grease
Jacket cooling	Yes

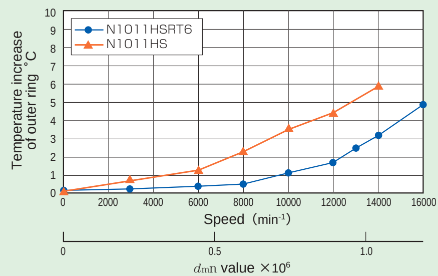

Fig. 10.12 High-speed test results (grease lubrication with outer case cooling)

【Test conditions】

Test bearing	N1016HSRT6 N1016HS (φ80×φ125×22)
Shaft speed	~22000 min⁻¹
Mounted radial clearance	0 μm
Lubrication	Air-oil lubrication
Oil consumption	0.02 mL/shot (oil shot intervals, 5 min)
Air consumption	40 NL/min
Jacket cooling	No

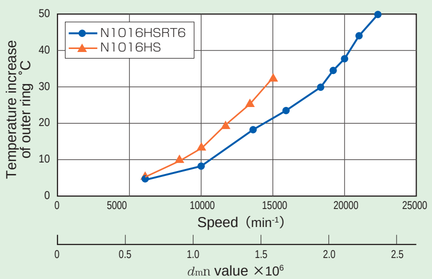

Fig. 10.13 High-speed test results (air-oil lubrication without jacket cooling)

【Test conditions】

Test bearing	N1016HSRT6 N1016HS (φ80×φ125×22)
Shaft speed	~22000 min⁻¹
Mounted radial clearance	0 μm
Lubrication	Air-oil lubrication
Oil consumption	0.02 mL/shot (oil shot intervals, 5 min)
Air consumption	40 NL/min
Jacket cooling	Yes

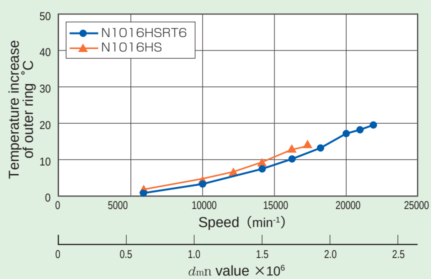

Fig. 10.14 High-speed test results (air-oil lubrication with jacket cooling)

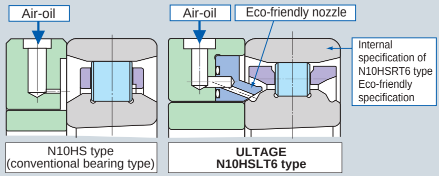
⑪ ULTAGE Eco-friendly air-oil lubricated cylindrical roller bearings N10HSLT6 type

The eco-friendly air-oil lubricated N10HSLT6 type was developed by applying **NTN**'s unique eco-conscious technology to the proven N10HSRT6 type bearing design. The N10HSLT6 type boasts limited emission of oil mist and reduced air and oil consumption. This improves operating environments, saves energy while allowing higher-speed machining operation.

■Features

1. Optimized internal design allows high speed operation and limits temperature increase.
2. Adoption of the eco-friendly nozzle design has led to:
   Lower noise level (up to 7 dBA)
   50% reduction in air consumption
   50% reduction in oil consumption.

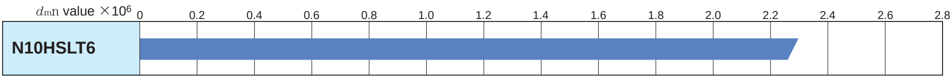
■Bearing specification



NOTE) The N10HSLT6 type is delivered as packed together with the spacer with the eco-friendly nozzle. The bearing type code N10HSLT6 represents the bearing proper, while a spacer code stands for an eco-friendly nozzle proper or a spacer having a built-in nozzle. For more details, see "③ Bearing Designations".

Fig. 10.15 N10HSLT6 type

■Permissible speed range



Notes) Permissible speed of each bearing (dmn value) varies depending on the specifications of the machine for which the bearing is used (motor drive system, cooling system, and construction around the bearing). Consider the optimal choice referring to the above guideline and contact **NTN**.

■High-speed running test

Even with decreased air consumption and oil consumption, the N10HSL type bearings can reliably operate at high speed of dmn 2.3×10⁶ (**Fig. 10.16, 10.17**).

【Test conditions】

Test bearing	N1016HSLT6 N1016HS (φ80×φ125×22)	
Shaft speed	~22000 min⁻¹	
Mounted radial clearance	0 μm	
Oil consumption	0.02 mL/shot	
	N1016HS	5 min intervals
	N1016HSL	10 min intervals
Air consumption	N1016HS	40 NL/min
	N1016HSL	20 NL/min
Jacket cooling	No	

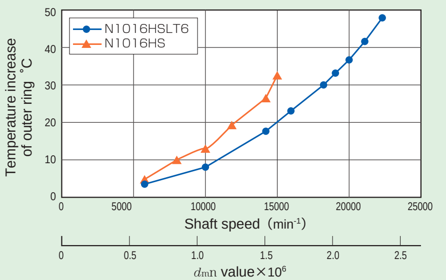


Fig. 10.16 Hgh-speed test results (without Jacket cooling)

【Test conditions】

Test bearing	N1016HSLT6 N1016HS (φ80×φ125×22)	
Shaft speed	~23000 min⁻¹	
Mounted radial clearance	0 μm	
Oil consumption	0.02 mL/shot	
	N1016HS	5 min intervals
	N1016HSL	10 min intervals
Air consumption	N1016HS	40 NL/min
	N1016HSL	20 NL/min
Jacket cooling	Yes

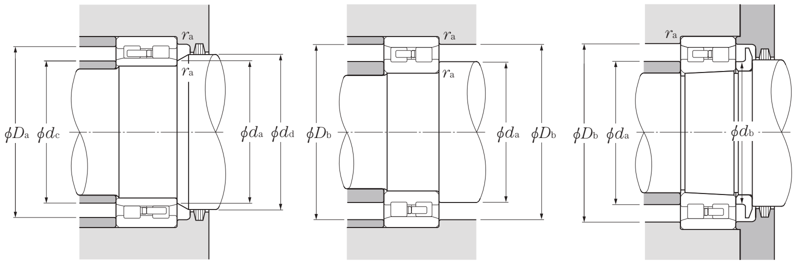
❶ A bearing number with suffix **K** indicates a tapered-bore bearing (taper ratio 1/12).
❷ Minimum allowable value for corner radius dimension r.
A part number containing a suffix **T6** means an **ULTAGE Series**.



Dynamic equivalent radial load
$P_r=F_r$

Static equivalent radial load
$P_{or}=F_r$

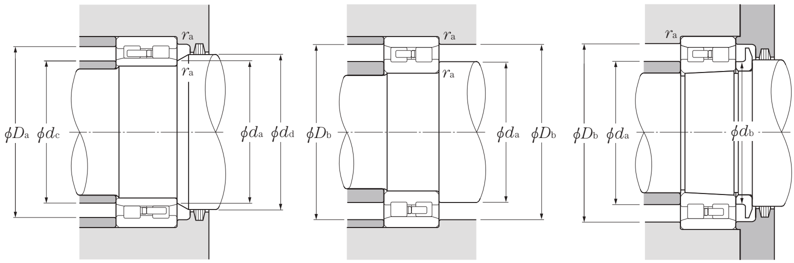
❶ A bearing number with suffix **K** indicates a tapered-bore bearing (taper ratio 1/12).
❷ Minimum allowable value for corner radius dimension r.
A part number containing a suffix **T6** means an **ULTAGE Series**



Dynamic equivalent radial load
$P_r = F_r$

Static equivalent radial load
$P_{or} = F_r$

⑬ Taper gage and internal clearance adjustment gage for NTN precision cylindrical roller bearings

As the need increases for machine tools of higher speed and precision, a higher degree of precision is required of machine tool bearings. For a precision bearing to exhibit its full performance, it must be installed correctly. In particular, when a tapered bore bearing is used, the corresponding taper on the shaft must be finished to a high degree of precision. **NTN** recommends the ring gage for the tapered shaft be finished to the same precision as for bearings. Note that the contact area between tapered faces should be 80% or greater.

NTN also offers a plug gage that permits verification of the precision of the ring gage. Remember that the radial internal clearance of a cylindrical roller bearing needs to be correctly adjusted. Too large a radial clearance can diminish the precision of the main spindle, while too small a radial clearance can lead to abnormal heat generation and premature flaking of the bearing. To ensure adequate internal clearance, use a mounted internal clearance adjustment gage.

Main Spindle Bearings

11. Angular Contact Ball Bearings for Axial Loads CONTENTS

11. Angular Contact Ball Bearings for Axial Loads

① Features and types

NTN provides a range of thrust bearings for the main spindles. This includes 5629 and 5620 series for high axial rigidity (contact angle 60˚) and HTA U(A) series high-speed duplex angular contact ball bearings for axial loads with optimized internal design (contact angle 40˚, 30˚). These bearings are used in conjunction with NN30, NN49, or NNU49 series double-row cylindrical roller bearings (matched bearings must have the same bore and outside diameter).

Table 11.1 Types of angular contact ball bearings for axial loads

	5629 and 5620 series	HTA0U (A)..DB, HTA9U (A)..DB series
Bearing type		Initial contact angle	60˚	40˚, 30˚
Cage material	High-strength machined brass cage	Molded resin, machined phenolic, high-strength machined copper alloy cage
Features	These series can withstand axial loads in both directions. Due to a larger contact angle, rigidity in axial directions is enhanced. The structure of these bearings limits them to grease-lubricated vertical shaft applications.	These duplex angular contact ball bearing series have similar design to the double-row thrust angular contact ball bearing series, but are different in terms of their widths (see the diagrams below). Since their contact angles are lower at 40° and 30°, the series boast high-speed capability. However, their axial rigidity is less than double-row thrust angular contact ball bearings with 60° contact angle.
Interchangeability	A double-direction thrust angular contact ball bearing can be readily interchanged with a duplex angular contact ball bearing simply by replacing spacer C with spacer D; the dimensions of the shaft and housing remain unchanged. Dimension *A* = Dimension 2*B*  Double-direction thrust angular contact ball bearing 5629 series 5620 series  High-speed duplex angular contact ball bearing for axial loads HTA9UDB series HTB0UDB series	

② Standard cage types

❷ The tolerance of outside diameter deviation $_{Ds}$ to be applied to the Class 4 and Class 2 is same as the tolerance of the mean outside diameter deviation $_{dmp}$.
Note that the Class 4 is applicable to diameter series 0 and 2, and the Class 2 is applicable to all the diameter series.
Note: This standard is the **NTN** standard.

⑥ Basic preload

The initial internal clearance or initial preload must be selected with consideration of the lubricating method, maximum speed, and required axial rigidity. Although usage with normal preload (GN) within the allowable speed range is possible for both grease lubrication and air-oil lubrication, ask **NTN** Engineering to recommend the appropriate preload if axial rigidity is required and you want to inhibit temperature rise of the main spindle. The standard preloads are summarized in **Table 11.7**.

Table 11.7 Basic preload

⑦ Shaft and housing fits

Fits given in **Table 11.8** are recommended for angular contact ball bearings for axial loads. To maintain high accuracy, provision of interference between the shaft and the bore of inner ring is essential. The fit of the housing and bearing should be same as that for cylindrical roller bearings, since an angular contact ball bearing is normally used together with a cylindrical roller bearing.

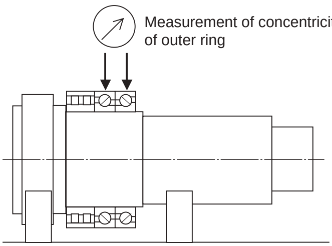

Fig. 11.1 Concentricity

■Checking concentricity of outside diameter of outer ring after bearing

Controlling concentricity of outer ring assembly is necessary for reduction of axial runout of the main spindle. Measure and control the concentricity of outer ring shown in **Fig. 11.1** and "6. Handling of Bearings, ② Mounting" in the Technical Data section.

Table 11.8 Fit to shaft

Unit: μm

Nominal bore diameter d mm over	incl.	Fit of inner ring to shaft
2.5	10	0～2T
10	18	0～2T
18	30	0～2.5T
30	50	0～3T
50	80	0～3.5T
80	120	0～4T
120	180	0～5T
180	250	0～6T

Note 1: Target the median value.
2: For high-speed applications where $d_m n$ value exceeds 0.75 ×10[6], the fit should be increased.For such an arrangement, consult **NTN** Engineering.
T: Tight (Interference) fit

⑧ Recommended lubrication specifications

Angular contact ball bearings for axial loads are usually used with grease lubrication or air-oil lubrication. Recommended specifications of the lubrication methods are described below.

■Grease lubrication

● Recommended brand of grease

Refer to "7. Lubrication of Bearings, ① Grease lubrication" in the Technical Data section.

● Recommended grease filling amount

$d_m n$ value ≦0.65×10[6]
15% of the capacity shown in the dimensions tables
$d_m n$ value ＞0.65×10[6]
12% of the capacity shown in the dimensions tables

● Recommended grease filling method

Refer to "6. Handling of Bearings, ① Cleaning and filling with grease" in the Technical Data section.

Notes: High-strength machined brass cages are used for 5629/5620 series. Thus, if they are used for grease-lubricated vertical shafts, the cage on one side may hang onto the rolling elements, possibly causing seizure. Use of the HTA series with resin cages or oil lubrication (including feeding of lubricating oil) is recommended.

■Air-oil lubrication

● Recommended location of nozzle

Refer to "7. Lubrication of Bearings ② Recommended location of nozzle for air-oil lubrication" in the Technical Data section.

● Recommended specifications of nozzle

Nozzle bore diameter : From 1 to 1.5 mm
Number of nozzles: One nozzle for each bearing, depth of nozzle bore should be four to six times of nozzle bore diameter.

● Recommended specifications of air-oil

Oil type: Spindle oil
Viscosity grade: ISO VG from 10 to 32 (32 is preferable)

Table. 11.9 Air and oil amount

Bearing types	$d_m n$ value (×10[6]) Over	Incl.	Oil amount per shot mL	Lubrication intervals min	Oil consumption mL/h	Recommended air consumption *NL/min
HTA9 (A)	～	1.0	0.03	8	0.23	20～40
HTA0 (A)	1.0 ～	1.2		5	0.36	
5S-HTA0 (A)						

＊NL/min (Normal liter/minute) … NL means the volume of air at 0˚C and 1 atmosphere.

⑨ ULTAGE Angular contact ball bearings for axial loads HTA U type

HTA U type angular contact ball bearing has a higher limiting speed with the same rigidity and loading capability as the conventional HTA series.

■Features

1. Optimized internal design to minimize the temperature rise especially at high speed range.
2. Improved molded nylon cage pocket design where the ball contacts to have improved lubrication performance under grease or air-oil lubrication.

■Bearings design

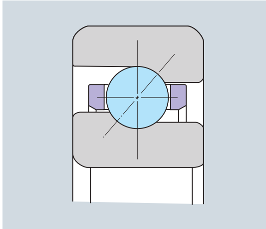

Fig. 11.2 HTA U type

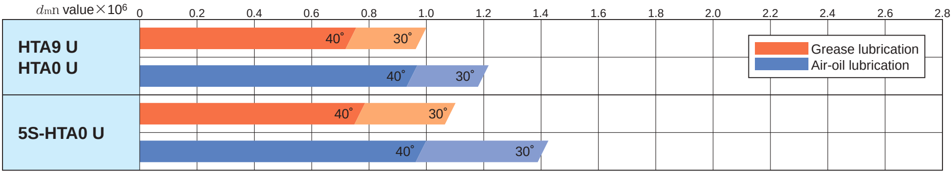
■Permissible speed range



Notes) Permissible speed of each bearing (d_mn value) varies depending on the specifications of the machine for which the bearing is used (motor drive system, cooling system, and construction around the bearing). Consider the optimal choice referring to the above guideline and contact **NTN**.

■Axial rigidity

Axial rigidity is at the same level as the conventional design.

【Calculation conditions】

Bearing	HTA020UA B , HTA020A B HTA020U B , HTA020 B (φ100×φ1 0 ×22. ×2 row)
ounted preload	α 30° 880 N α 40° 14 0 N

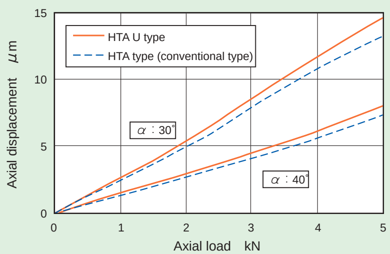


Fig. 11.3 Axial load and rigidity

■Data/Allowable axial load

By reviewing the internal structure, the allowable axial load has improved over HTA types by about 1.3 times with the contact angle of 30° and by about 1.2 times with the contact angle of 40°.

【Calculation conditions】

Bearing	HTA020UADB, HTA020ADB HTA020UDB, HTA020DB (φ100×φ150×22.5×2 row)

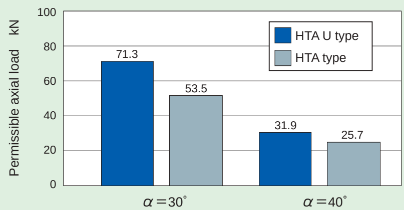

Fig. 11.4 Comparison of permissible axial load

■High speed test

d_mn value of 1.0×10⁶ under grease lubrication and 1.25×10⁶ under air-oil lubrication are realized by the optimized internal design. (**Fig.11.5～11.8**)

Main Spindle Bearings

12. Tapered Roller Bearings CONTENTS

12. Tapered Roller Bearings

Tapered roller bearings are designed so that the apexes of the inner ring, outer ring, and rollers are located at a common point on the bearing center line. Accordingly, the rollers roll on the raceway surfaces and slide along the back rib of the inner ring cone, guided by the resultant force from the inner ring and outer ring raceways.

This bearing is suitable for handling a radial load, an axial load in one direction, and the resultant load. Also, it has a large load capacity.

In general, the cage of a tapered roller bearing is a punched steel plate type. If P4 or higher is needed for running accuracy, **NTN** recommends that a high-strength machined brass cage to be used.

① Load calculation

Tapered roller bearings are generally used in pairs, so their dynamic equivalent load can be calculated according to **Table 12.1.**

② Bearing designations

329 18 X U DB +xx P4

- **P4** — **Tolerance class code**
  - P5: JIS class 5
  - P4: JIS class 4
  - UP: **NTN** special high precision
- **+xx** — **Spacer width dimension**
- **DB** — **Duplex arrangement code**
  - DB: Back-to-back
  - DF: Face-to-face
- **U** — **Internal modification code**
- **18 X** — **Nominal bore diameter**
- **329** — **Bearing series code**

Table 12.1 Bearing arrangement and equivalent load

Bearing arrangement		Load condition	Axial load	Equivalent radial load
DB arrangement		$\frac{0.5F_{rI}}{Y_I} \leqq \frac{0.5F_{rII}}{Y_{II}} + F_a$	$F_{aI} = \frac{0.5F_{rII}}{Y_{II}} + F_a$	$P_{rI} = XF_{rI} + Y_I\left(\frac{0.5F_{rII}}{Y_{II}} + F_a\right)$
			$F_{aII} = \frac{0.5F_{rII}}{Y_{II}}$	$P_{rII} = F_{rII}$
DF arrangement		$\frac{0.5F_{rI}}{Y_I} > \frac{0.5F_{rII}}{Y_{II}} + F_a$	$F_{aI} = \frac{0.5F_{rI}}{Y_I}$	$P_{rI} = F_{rI}$
			$F_{aII} = \frac{0.5F_{rI}}{Y_I} - F_a$	$P_{rII} = XF_{rII} + Y_{II}\left(\frac{0.5F_{rI}}{Y_I} - F_a\right)$
DB arrangement		$\frac{0.5F_{rII}}{Y_{II}} \leqq \frac{0.5F_{rI}}{Y_I} + F_a$	$F_{aI} = \frac{0.5F_{rI}}{Y_I}$	$P_{rI} = F_{rI}$
			$F_{aII} = \frac{0.5F_{rI}}{Y_I} + F_a$	$P_{rII} = XF_{rII} + Y_{II}\left(\frac{0.5F_{rI}}{Y_I} + F_a\right)$
DF arrangement		$\frac{0.5F_{rII}}{Y_{II}} > \frac{0.5F_{rI}}{Y_I} + F_a$	$F_{aI} = \frac{0.5F_{rII}}{Y_{II}} - F_a$	$P_{rI} = XF_{rI} + Y_I\left(\frac{0.5F_{rII}}{Y_{II}} - F_a\right)$
			$F_{aII} = \frac{0.5F_{rII}}{Y_{II}}$	$P_{rII} = F_{rII}$

Note 1: The above are valid when the bearing internal clearance and preload are zero.
2: Radial forces in the opposite direction to the arrow in the above illustration are also regarded as positive.

③ Accuracy

250	315	0	−25	0	−18	19	14	13	9	18	11	13	8	10

❷ The tolerance of outside diameter deviation *Ds* applicable to class 4 is the same as the tolerance of single plane mean outside diameter deviation *Dmp*.

④ Recommended fit for high-precision tapered roller bearings

Table 12.4 Fit to shaft

Unit: μm

Nominal bore diameter *d* mm		Fit between inner ring and shaft	
		Fixed side	Floating side
over	incl.	Targeted ❶ interference	Targeted ❶ interference
18	30	0～5T	0～1T
30	50	0～6T	0～2T
50	80	0～7T	0～3T
80	120	0～8T	0～4T
120	180	0～10T	0～5T
180	250	0～13T	0～6T
250	315	0～15T	0～6T
315	400	0～18T	0～8T

❶ Target the median value.
T: Tight (Interference)

Table 12.5 Fit to housing

Unit: μm

Nominal bore diameter *D* mm		Fit between outer ring and housing
over	incl.	Targeted interference ❶
30	50	3L～3T
50	80	3L～3T
80	120	4L～4T
120	150	5L～5T
150	180	5L～5T
180	250	6L～6T
250	315	7L～7T
315	400	8L～8T
400	500	9L～9T

For precision main spindles, the tight (interference) side of the targeted interference is recommended for the precision tool side.

⑤ Dimension tables for tapered roller bearings

Ball Screw Support Bearings

13. Ball Screw Support Bearings CONTENTS

13. Ball Screw Support Bearings

NTN ballscrew bearings are optimized to support a ballscrew.
These bearings are categorized as shown in **Table 13.1**.

Table 13.1 Bearing types

Type code	Notes	Bore diameter
BST **2A-BST**	Open type thrust angular contact ball bearing with 60˚ contact angle, generally used with grease lubrication	φ17〜φ60
BST LXL/L588 **2A-BST LXL/L588**	Grease-lubricated sealed angular contact ball bearing with 60˚ contact angle	φ17〜φ60
BSTU LLX/L588	Grease-lubricated sealed double row thrust angular contact ball bearing unit with 60˚ contact angle	φ20〜φ100
HT	Duplex angular contact ball bearing with 30˚ contact angle, generally used with grease lubrication	φ6〜φ40
AXN	Needle roller bearing with double-direction thrust needle roller bearing, generally used with oil lubrication	φ20〜φ50
ARN	Needle roller bearing with double-direction thrust cylindrical roller bearing, generally used with oil lubrication	φ20〜φ70

① ULTAGE Angular contact thrust ball bearings BST-1B (LXL/L588), 2A-BST-1B (LXL/L588) series

The 2A-BST type incorporates the maximum possible number of small balls (compared with those of a standard bearing), has thicker inner and outer rings, and a larger contact angle of 60˚. Thus, this type of bearing boasts greater axial rigidity. Additionally, since balls are used as the rolling elements, the starting torque of a angular contact thrust ball bearing is less than that of a roller bearing.

Open (BST and 2A-BST type) and light-contact seals (BST LXL and 2A-BST LXL type) are available and molded resin cages are standard.

Side faces of BST type bearings are flush-ground to provide the same face height difference for both the front and back faces. As a result, bearings of the same part number can be freely combined into DB, DBT, DTBT configurations as illustrated in **Fig. 13.2**, and the adjustment for a relevant preload is no longer necessary.

Every single bearing is machined to the same face height so that when any arrangement is installed on a ballscrew the unit has optimal preload. For this reason, no time-consuming preload adjustment (adjustment with shims or tightening and loosening while measuring the starting torque) is necessary.

■Features 2A-BST-1B (LXL/L588)

1. Unique heat treatment greatly improves resistance against rolling contact fatigue, leading to longer service life (approximately two times that of the conventional type).
2. Both sides are sealed to enhance contamination resistance and to preserve the grease. (Light-contact seal type)
3. Special long-life grease is used. (Light-contact seal type)
4. The combination of a unique heat treatment and special grease reduces fretting (by 80% or more for sliding mode, 90% or more for rolling mode, compared to the conventional type). (Light-contact seal type)
5. Pre-greased bearings eliminate the need for further grease packing and allow easier handling. (Light-contact seal type)

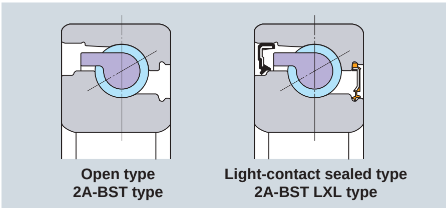

Fig. 13.1

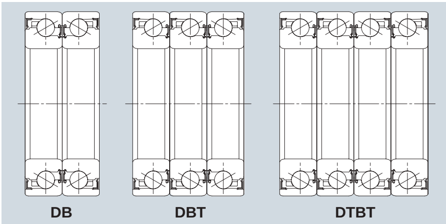

Fig. 13.2 Bearing arrangement

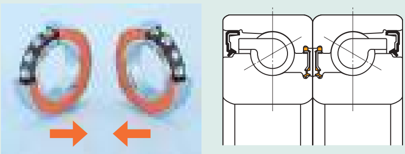
■Easy handling

2A-BST LXL type and BST LXL grease-lubricated sealed angular contact ball bearings eliminate the need for grease filling because they have been packed with grease in advance. You need to only wipe away rust preventive oil before use. Seals in different colors are used for the front and back sides.

The front side (black) and back side (orange) can be identified by the color of a seal, and you can easily check configuration during assembly.

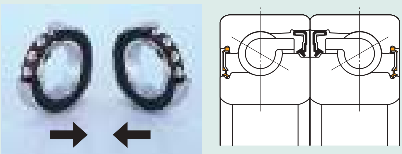
DB set (back faces in combination)

Orange seal + Orange seal



DF set (front faces in combination)

Black seal + Black seal



■Performance tests 2A-BST-1B (LXL/L588)

Ball screw support bearings have a unique internal design in order to lengthen service life and enhance resistance to fretting.

(1) Fretting resistance test (sliding)

Resistance to fretting while sliding is tested by the fretting resistance test. A conceptual drawing of the test is shown in **Fig. 13.3**, and the test conditions are shown in **Table 13.3**. In this test, a fixed ball is pushed against a plate, and reciprocated for a fixed period. The volume of ball and plate wear depth are checked after testing as shown in **Fig. 13.4**.

Due to a unique heat treatment and special grease (light-contact seal type), amount of wear is reduced to 1/5 or less compared to the conventional type consisting of standard SUJ2 plate material and lithium-based general purpose grease. (**Fig. 13.4**)

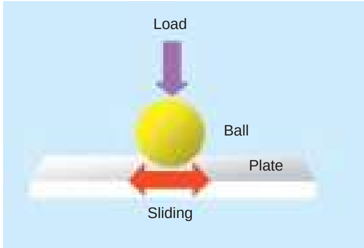


Fig. 13.3 Fretting resistance test (sliding)

Table 13.3 Test conditions

Material	Plate	Conventional type (SUJ2 without special heat treatment)
		ULTAGE series (SUJ2 with special heat treatment)
	Ball	SUJ2
Load (N)		98
Max. contact surface pressure (MPa)		2560
Loading frequency (×10^5cycle)		Test time: 8 h
Sliding cycle (Hz)		30
Amplitude (mm)		0.47
Lubrication		Grease
Temperature		Room temperature

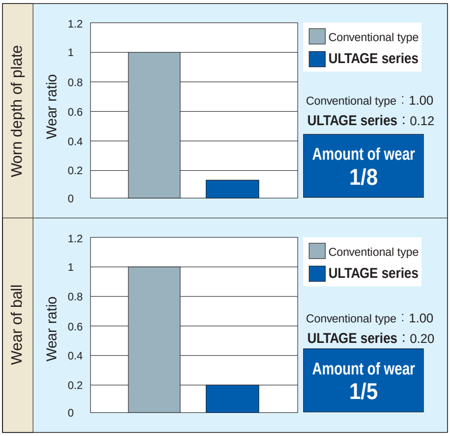

Fig. 13.4 Ratio of fretting corrosion in sliding mode

(2) Fretting resistance test (rolling)

Resistance against fretting while rolling is tested in the rotating and oscillating type fretting corrosion test. A conceptual drawing of the test is shown in **Fig. 13.5**, and the test conditions are shown in **Table 13-4**. In this test, a housing plate is fixed, and the shaft plate oscillates. The decrease in the weight of the bearing plate after the test is shown in **Fig. 13.6**.

Due to the combination of a unique heat treatment and a special grease (light-contact seal type), the amount of wear is reduced to 1/10 or less compared to the conventional type consisting of standard SUJ2 steel rings and lithium based general purpose grease. (**Fig. 13.6**).

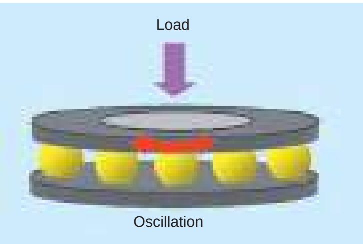

Fig. 13.5 Fretting resistance test (rolling)

Table 13.4 Test conditions

Bearing (mm)	Evaluated with thrust ball bearing 51204 (φ20×φ40×14)
Load (kN)	2.5
Max. contact surface pressure (MPa)	1700
Test time (h)	8
Oscillating cycle (Hz)	30
Oscillating angle (deg)	12
Lubrication	Grease
Temperature	Room temperature

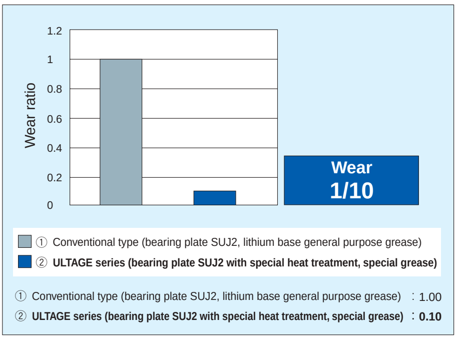

Fig. 13.6 Ratio of fretting corrosion while rolling

(3) Rolling contact fatigue life test

Resistance to rolling contact fatigue is improved as a result of a special heat treatment, leading to a longer service life compared to the standard heat-treated type model in both clean and contaminated oil. (**Fig. 13.7**)

Table 13.5 Test conditions

Bearing (mm)	Evaluated with deep groove ball bearing 6206 (φ30×φ62×16)
Radial load (kN)	6.86
Shaft speed (min^{-1})	2000
Lubrication	VG56 turbine oil
Atmosphere temperature (˚C)	60

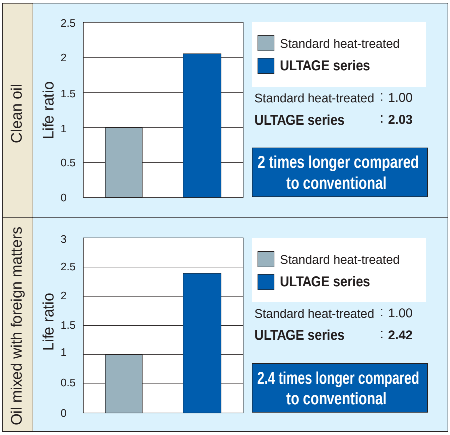

Fig. 13.7 Effect of special heat treatment on rolling contact fatigue life

(4) Grease life test

Service life of the grease has been dramatically extended compared to lithium-base general purpose grease (**Fig. 13.8**).

(Special grease is available for only the light-contact seal type.)

Table 13.6 Test conditions

Bearing (mm)	Evaluated with deep groove ball bearing 6204 (φ20×φ47×14)
Radial load (N)	67
Axial load (N)	67
Shaft speed (min^{-1})	10000
Atmosphere temperature (˚C)	150

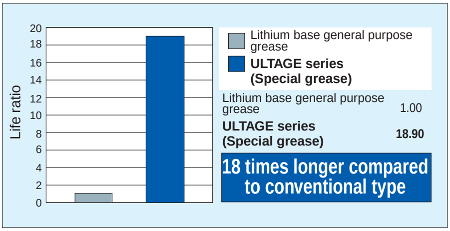

Fig. 13.8 Grease life ratio

(5) Grease leakage test

Light-contact type seals eliminate grease leakage from the bearing. (**Fig. 13.9**)

Table 13.7 Test conditions

Atmosphere	Room temperature

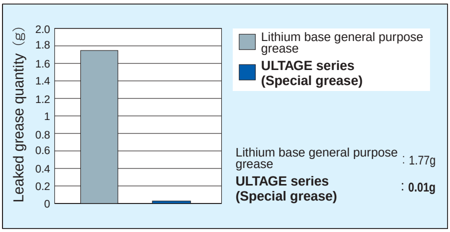

Fig. 13.9 Grease leakage

② *ULTAGE* Double row thrust angular contact ball bearing unit BSTU

The BSTU type is ball screw support bearing unit with two inner rings and one outer ring, in a back-to-back duplex arrangement. The outer ring has mounting holes for the housing for easier handling and the use of a newly developed seal ensures low torque and high dust resistance.

■Features

1. Greater load capacity with optimizations made to the internal bearing design.
2. Use of newly developed light-contact seal to achieve both low torque and high dust resistance.
3. The long operating life of the BST type, and use of special grease with excellent fretting resistance.
4. Outer ring mounting hole, and sealed grease lubrication groove for easier handling.
5. Specifications combining two of these units (D2) are also available for high-load capacity applications.

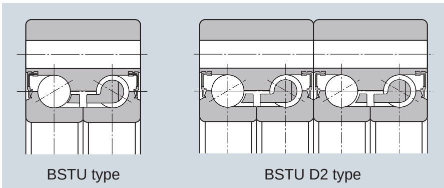

Fig. 13.10 BSTU

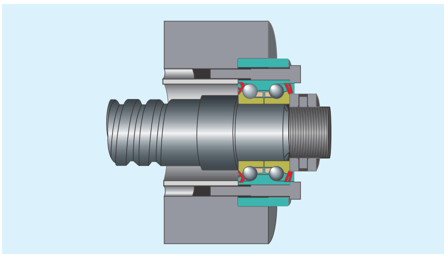

Fig. 13.11 E ample of mounted BSTU type installatio n

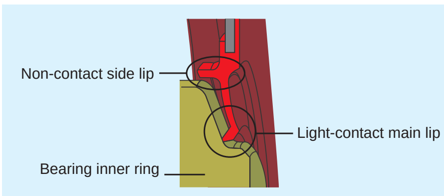

Fig. 13.1 Light-contact seal (code L)

■Performance tests

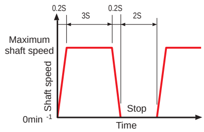
(1) Bearing operating test

The BSTU type exhibit stable temperature rises up to 5000 min^{-1} ($d_m n$ value 0.225×10^6) due to optimizations made to the internal bearing design and the use of a newly developed light-contact seal.(**Fig. 13.13**)

[Test conditions]

Bearing (mm)	BSTU3080LLX/GNP4U/L588 (φ30Xφ80X28)
Shaft speed (min^{-1})	Max. 5000

The operating pattern at each shaft speed is shown to the right.



Temperature increase test operating pattern

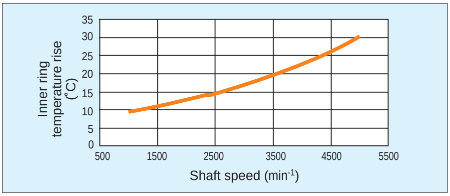


Fig. 13.13 Relation between shaft speed and temperature rise

(2) Torque test, dust test

The BSTU type limits starting torque and has better dust resistance with the use of a newly developed light-contact seal. (**Fig. 13.14**, **Fig. 13.15**)

[Test conditions]

Bearing (mm)	BSTU3080LLX/GNP4U/L588 (φ30Xφ80X28)

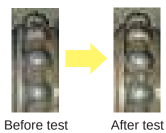
Bearing (mm)	BSTU3080LLX/GNP4U/L588 (φ30Xφ80X28)
Shaft speed (min^{-1})	2200
Dust particle diameter	5 to 75 µm (8 types of test powder 1 JIS Z8901)
Dust color phase	Brown
Test time	1 hour



Bearing internal conditions before and after test
(with bearing outer ring removed)
No foreign matter was observed inside the bearing after test.

Fig. 13.15 Dust test results

③ Duplex angular contact ball bearings HT series

HT type duplex angular contact ball bearings feature larger axial load capacity while maintaining the same dimensions as a standard angular contact ball bearing (contact angle: 30˚). Bearings smaller than the BST type are available for use in small products.

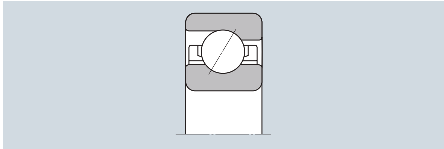


Fig. 13.10 HT

④ Needle roller bearings with double-row thrust needle roller bearings AXN series
Needle roller bearings with double-row thrust cylindrical roller bearings ARN series

AXN and ARN type bearings have thrust needle roller or thrust cylindrical roller bearings on both sides of a radial needle roller bearing. The outer ring side face of the radial needle roller bearing is used as the raceway of both thrust bearings. These bearings can withstand axial loads in both directions while maintaining compact designs. The radial needle roller bearings are suitable for heavy radial loads.

The axial rigidity of the AXN type is extremely enhanced since the thrust needle roller bearings are used for axial loads.

Likewise, the axial rigidity of the ARN type is improved. Since the axial load capacity of this type is larger than the AXN type, this type is suitable for heavy axial loads. Oil lubrication is recommended for the ARN type.

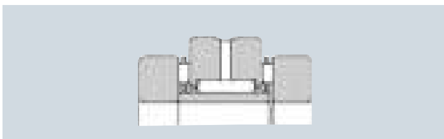

Fig. 13.11 AXN

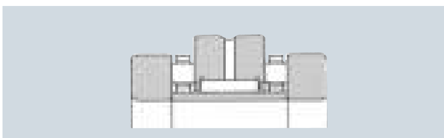

Fig. 13.12 ARN

⑤ Bearing designations

The part number for a ballscrew bearing consists of a type code, dimension code, and various suffixes.

■2A-BST type

2A - BST 20 × 47 −1B LXL DBT P4 / L588

- **Grease code**
  L588: Urea based special grease
- **Tolerance class code**
  P5: JIS Class 5 (equivalent)
  P4: JIS Class 4 (equivalent)
  UP: **NTN** Class
- **Arrangement code**
- **Seal code**
  LXL:Light contact rubber seals
- **Identification code**
  Preload code and added number
  -1B: Standard preload
  -11B: Light preload
- **Outside diameter (mm)**
- **Nominal bore diameter (mm)**
- **Bearing type code**

- **Bearing type code**

⑤ Bearing precision

The precision of ballscrew bearings varies depending on the bearing type.

- **2A-BST type**
  Available in **NTN** class 5 (tolerance class code P5), class 4 (tolerance class code P4) each complying with JIS standards, and grade UP (tolerance class code UP). The classes are listed in ascending order.
- **70HT type**
  Same precision as the main spindle angular contact ball bearing. Classes 5 and 4 are available.
- **AXN, ARN types**
  NTN standard classes 4 and 5 complying with the JIS standards.

■Accuracy of 2A-BST type

⑦ Basic preload and axial rigidity

Basic preloads for each type of ball screw support bearings are shown in the dimension tables. The preloads can be altered depending on the required rigidity. Contact **NTN** in such a case. In the AXN and ARN types, rigidity is normally enhanced by tightening the thrust bearing rings to supply preload. Preloads and torques are shown in the dimensions tables to help control basic preload. A bearing that allows preset preload by tightening the bearing raceways to adjust the clearance A between the thrust bearing ring and radial bearing ring (**Fig. 13.19**) is also available. Ask **NTN** for details.

Axial rigidity of the 2A-BST type DB duplex arrangement and the AXN type at the basic preload are shown in **Figs. 13.20** and **13.21**.

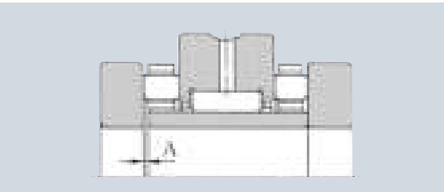

Fig. 13.19

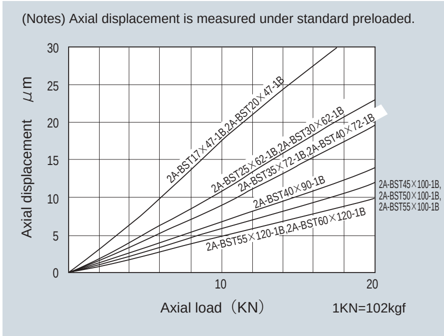

Fig. 13.20 BST type rigidity chart

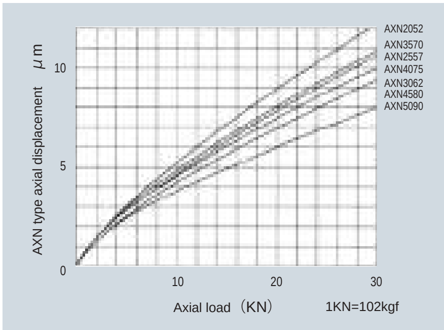

Fig. 13.21 AXN type rigidity chart

⑧ Shaft and housing fits

Recommended fit and tolerances of shaft and housing shoulder squareness are shown in **Tables. 13.17** and **13.18**.

Table 13.17 Shaft and housing fits

—	30	4	4	4	4
30	80	4	4	4	5
80	120	5	5	—	6
120	180	—	—	—	7

⑨ Applications

The BST type is mainly installed on ball screws of machine tool feed systems, and two to four row arrangements are used in many cases. This type is popular because greased sealed angular contact ball bearings are easy to handle. The back-to-back duplex arrangement is commonly used because it allows acquisition of the specified preload by tightening the inner ring. The face-to-face duplex arrangement may be used if more precise alignment is required. It is not commonly used for machine tools. Examples of bearing arrangement are shown in **Figs. 13.22** and **13.24**.

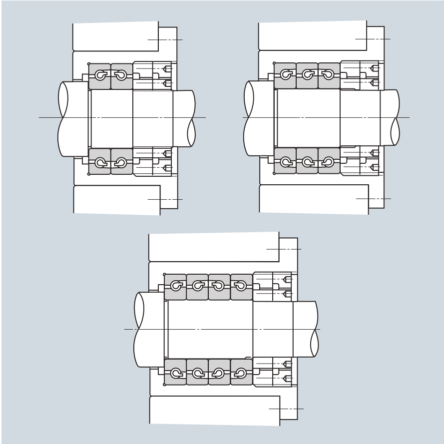

Fig. 13.22

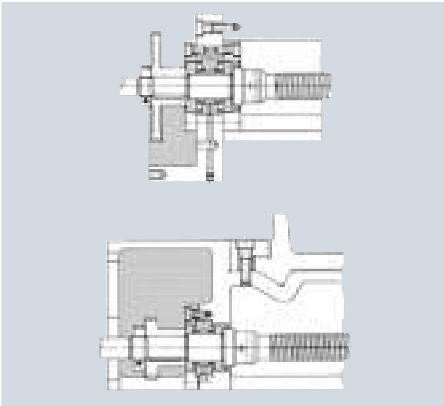

Fig. 13.23

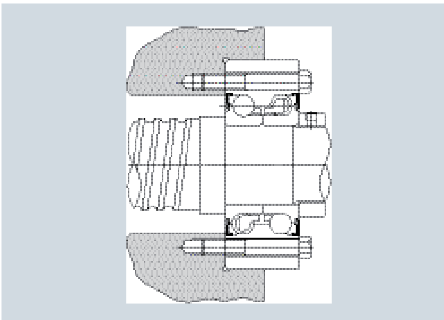

Fig. 13.24

⑩ Starting torque of 2A-BST type

Reference starting torque values for 2A-BST bearings are shown in **Tables 13.19** and **13.20**.

Table 13.19 Open type BST and 2A-BST

⑪ Recommended lubrication specifications

BST and HT ball screw support angular contact ball bearings are generally lubricated with grease. (BST LXL bearings with light-contact seals are packed with grease.) AXN and ARN bearings are generally lubricated with circulated oil.

■Grease lubrication

● **Recommended type of grease**
Lithium-mineral oil base general purpose grease of which base oil viscosity is high (for example, Alvania Grease S2, Shell).

● **Recommended grease fill**
25% of the capacity shown in the dimensions tables

● **Recommended grease filling method**
Refer to "6. Handling of Bearings, ① Rinsing of bearings and grease filling" in the Technical Data section.

■Oil lubrication

● **Recommended type of oil**
Hydraulic oils or other industrial oils used for lubrication of sliding surfaces with viscosity grade ISO VG 68 or higher are recommended.

● **Oil quantity**
Recommended oil quantity depends on the lubricating method. As a general guideline, the oil flow rate should be 5 to 10 cm^3/min.

⑫ Dimension tables

14. NTN Products

Cam followers for pallet changer

Cam followers are often used on work piece transfer systems (such as pallet changers) of machine tools (such as machining centers) to handle the large loads generated by these systems.
NTN offers various types of cam followers that include a ready-to-install cam follower optimized for pallet changers.

① Structure and features

- The outer ring wall thickness is maximized for resistance to heavy load or impact load.
- **NTN** cam followers for pallet changers feature a compact design and can be easily mounted by tightening a setscrew.
- The outer diameter, outer ring width, and stud diameter are identical to the dimensions of **NTN**'s standard cam followers (KR type).
- Because cam followers for pallet changers are actuated less frequently, they do not need to be relubricated. The oil hole has been deleted.
- Cost is reduced by removing the grease hole and the thread from the stud.

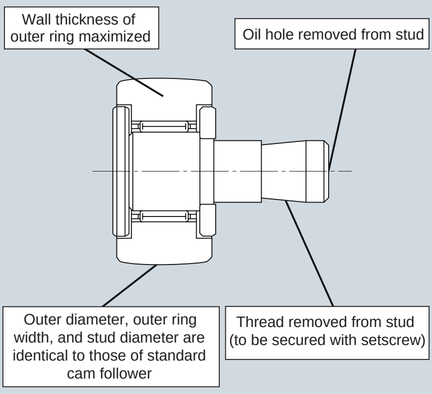

Fig. 14-1 Schematic of NTN pallet changer cam follower

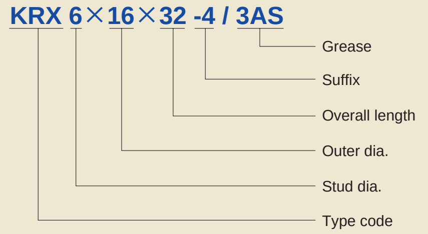
② Cam follower numbering

The part number for cam followers for pallet changers is same as that of **NTN** special cam followers.



③ Accuracy

The accuracy of **NTN** cam followers for pallet changer is same as that of **NTN** standard cam followers (JIS class 0).

④ Fit

The **NTN** pallet changer cam follower has a special stud that is readily secured with a setscrew. As illustrated below, a setscrew locks the pallet changer cam follower in the axial and circumferential directions.

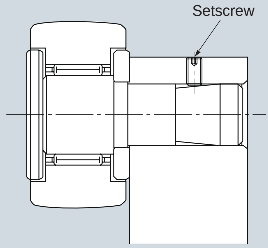


Fig. 14-2 Typical mounting arrangement

⑤ Radial internal clearance

The radial clearance of **NTN** cam followers for pallet changers is same as that of **NTN** standard cam followers (**Table 14-1**).

Table 14-1. Inner ring

Nominal inscribed circle diameter F_w		Clearance CN (normal clearance)	
over	incl.	min	max
3	6	3	17
6	10	5	20
10	18	5	25
18	30	10	30
30	50	10	40

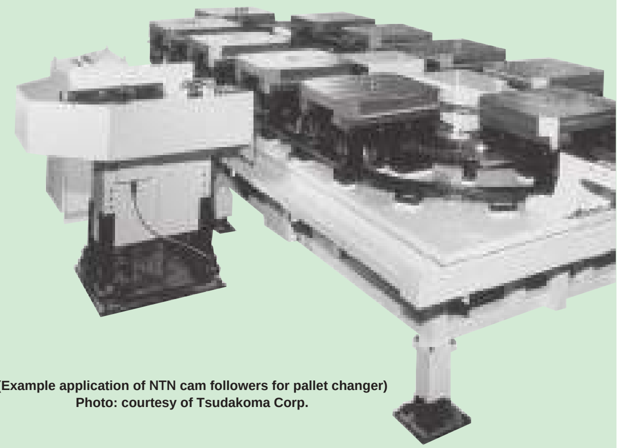
⑥ Lubrication

NTN cam followers for pallet changers are prefilled with lithium based grease and can be used in a temperature range of -25 to +100˚C.

Under the assumption that the user does not perform relubrication with grease, the standard **NTN** pallet changer cam follower does not have an oil hole for relubrication. (If necessary, the cam follower can be provided with an oil hole or a hole for mounting a grease nipple.)

Upon request, **NTN** can also provide cam followers with a synthetic rubber seal.

Lubrication between the outside surface of bearing and track is also necessary. Failure to properly lubricate the outside surface of the cam follower could lead to premature wear of the bearing.



(Example application of NTN cam followers for pallet changer)

Table 2: Comparison of SI, CGS and gravity units-1

Quantity / Unit system	Length L	Mass M	Time T	Acceleration	Force	Stress	Pressure	Energy
SI	m	kg	s	m/s^2	N	Pa	Pa	J
CGS system	cm	g	s	Gal	dyn	dyn/cm^2	dyn/cm^2	erg
Gravitation system	m	kgf · s^2/m	s	m/s^2	kgf	kgf/m^2	kgf/m^2	kgf · m

Table 3: SI-customary unit conversion table-1

Quantity	Unit designation	Symbol	Conversion rate to SI	SI unit designation	Symbol
Angle	Degree	°	π/180	Radian	rad
	Minute	′	π/10 800		
	Second	″ (sec)	π/648 000		
Length	Meter	m	1	Meter	m
	Micron	μ	10^{-6}		
	Angstrom	Å	10^{-10}		
Area	Square meter	m^2	1	Square meter	m^2
	Are	a	10^2		
	Hectare	ha	10^4		
Volume	Cubic meter	m^3	1	Cubic meter	m^3
	Liter	R.L	10^{-3}		
Mass	Kilogram	kg	1	Kilogram	kg
	Ton	t	10^3		
	Kilogram force / square second per meter	kgf · s^2/m	9.806 65		
Time	Second	s	1	Second	s
	Minute	min	60		
	Hour	h	3 600		
	Day	d	86 400		
Speed	Meters per second	m/s	1	Meters per second	m/s
	Knot	kn	1 852/3 600		
Frequency and vibration	Cycle	s^{-1} (pps)	1	Hertz	Hz
Revolutions (rotational speed)	Revolutions per minute (rpm)	rpm [min^{-1}]	1/60	Per second	s^{-1}
Angular speed	Radians per second	rad/s	1	Radians per second	rad/s
Acceleration	Meters per square second	m/s^2	1	Meters per second square	m/s^2
	G	G	9.806 65		
Force	Kilogram force	kgf	9.806 65	Newton	N
	Ton force	tf	9 806.65		
	Dyne	dyn	10^{-5}		
Force moment	Kilogram force / meter	kgf · m	9.806 65	Newton meter	N · m
Inertia moment	Kilogram force / meter / square second	kgf · m · s^2	9.806 65	Kilogram / square meter	kg · m^2
Stress	Kilogram force per square meter	kgf/m^2	9.806 65	Pascal or newton per square meter	Pa or N/m^2
Pressure	Kilogram force per square meter	kgf/m^2	9.806 65	Pascal	Pa
	Meter water column	mH_2O	9 806.65		
	Meter of mercury	mHg	101 325/0.76		
	Torr	Torr	101 325/760		
	Atmosphere	atm	101 325		
	Bar	bar	10^5		
Energy	Erg	erg	10^{-7}	Joule	J
	IT calorie	cal_{IT}	4.186 8		
	Kilogram force / meter	kgf · m	9.806 65		
	Kilowatt hour	kW · h	3.600×10^6		
	Metric horsepower per hour	PS · h	$2.647\ 79 \times 10^6$		
Power rate and power	Watt	W	1	Watt	W
	Metric horsepower	PS	735.5		
	Kilogram force / meter per second	kgf · m/s	9.806 65		

Table 2: Comparison of SI, CGS and gravity units-2

Unit system \ Quantity	Power rate	Temperature	Viscosity	Dynamic viscosity	Magnetic flux	Flux density	Magnetic field strength
SI	W	K	Pa · s	m^2/s	Wb	T	A/m
CGS system	erg/s	˚C	P	St	Mx	Gs	Oe
Gravitation system	kgf · m/s	˚C	kgf · s/m^2	m^2/s	—	—	—

Table 3: SI-customary unit conversion table-2

Quantity	Unit designation	Symbol	Conversion rate to SI	SI unit designation	Symbol
Viscosity	Poise	P	10^{-1}	Pascal second	Pa · s
	Centipoise	cP	10^{-3}		
	Kilogram force / square second per meter	kgf · s/m^2	9.806 65		
Dynamic viscosity	Stokes	St	10^{-4}	Square meter per second	m^2/s
	Centistokes	cSt	10^{-6}		
Temperature	Degree	˚C	+273.15	Kelvin	K
Radioactive	Curie	Ci	3.7×10^{10}	Becquerel	Bq
Dosage	Roentgen	R	2.58×10^{-4}	Coulombs per kilogram	C/kg
Absorption dosage	Rad	rad	10^{-2}	Gray	Gy
Dosage equivalent	Rem	rem	10^{-2}	Sievert	Sv
Magnetic flux	Maxwell	Mx	10^{-8}	Weber	Wb
Flux density	Gamma	γ	10^{-9}	Tesla	T
	Gauss	Gs	10^{-4}		
Magnetic field strength	Oersted	Oe	$10^3/4\pi$	Amperes per meter	A/m
Quantity of electricity	Coulomb	C	1	Coulomb	C
Potential difference	Volt	V	1	Volt	V
Electric resistance	Ohm	Ω	1	Ohm	Ω
Current	Ampere	A	1	Ampere	A

Table 4: Tenth power multiples of SI unit

Multiples of unit	Prefix		Multiples of unit	Prefix	
	Name	Symbol		Name	Symbol
10^{18}	Exa	E	10^{-1}	Deci	d
10^{15}	Peta	P	10^{-2}	Centi	c

〔How to read the table〕 If for example you want to convert 10 kgf to N, find "10" in the middle column of the first set of columns on the right. Look in the N column directly to the right of "10," and you will see that 10 kgf equals 98.066 N. Oppositely, to convert 10 N to kgf, look in the kgf column to the right of "10" and you will see that 10 N equals 1.0197 kgf.

1kgf＝9.80665N
1N＝0.101972kgf

Needle Roller Bearing Handbook

Index

1. Needle Roller Bearings

1. 1 Classification of needle roller bearings

Needle roller bearings are categorized into the following two groups:

- **Needle roller and cage assembly bearings**
- **Full-complement needle roller bearings**

1. 2 Comparison with general bearings

(1) Greater load-bearing capacity in a more compact design

Needle roller bearings are smaller than general bearings but have a greater load-carrying capacity. This advantage allows for more compact designs for bearings as well as for bearing housings. Use of these bearings lowers costs by allowing for lighter-weight machinery and more compact structures.

Fig. 1.1 compares bearings with (30) mm bore diameters. Needle roller bearings have 2 to 8 times the load-carrying capacity per given mass than other bearing types.

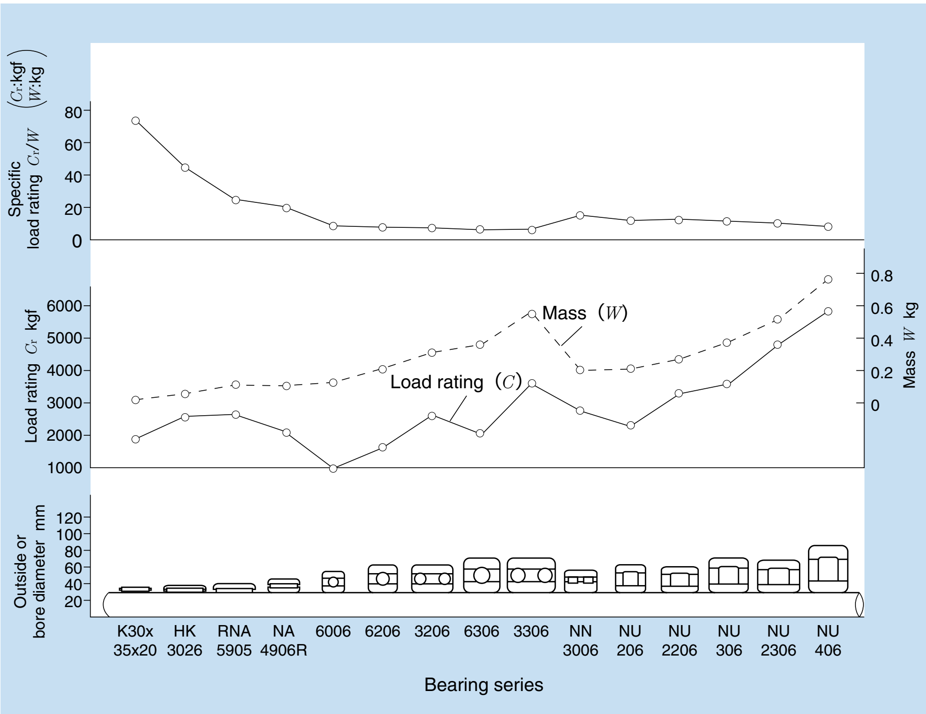

Fig. 1.1

1

Fig. 1.2 shows a comparison of bearing sizes of standard dimensions and similar load-carrying capacity. Needle roller bearings have one-half the outside diameter and one-fifth the mass of deep-groove ball bearings.

Needle roller and cage assembly bearings differ from general bearings in that, if the shaft and bearing housing can be made to a specific hardness, accuracy, and surface roughness, the needle roller and cage assemblies can function as independent bearings without inner and outer rings. Bearings used in this way are smaller and can be used in the same space as a metal bearing.

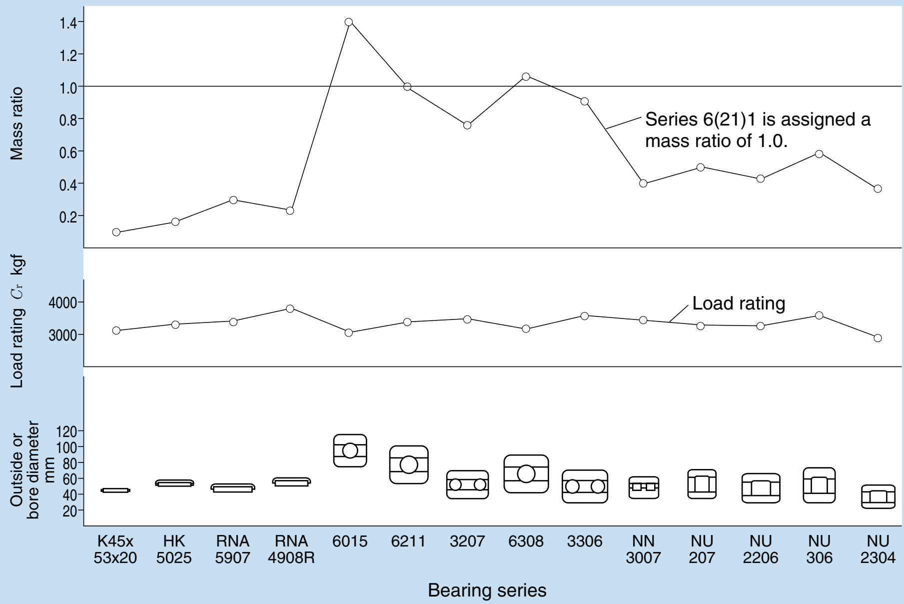

Fig. 1.2

1

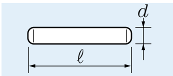
(2) Low inertial force

Because needle roller and cage assemblies have a smaller mass, these bearings are particularly useful for applications in which a smaller inertial force is required, such as in an engine crankshaft. (**Fig. 1.3**)

(3) High rigidity

Fig. 1.4 shows the elastic displacement when the radial load is applied to various bearings with similar basic load ratings.

1. Needle roller bearings have the following characteristics in comparison to cylindrical roller bearings.
   - More rollers are included.
   - ℓ /d is greater.



2. Needle roller bearings have greater rigidity because the load carried per unit area is smaller than ball bearings.

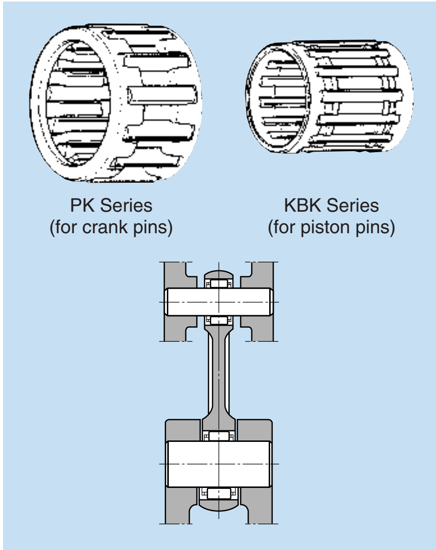


Fig. 1.3

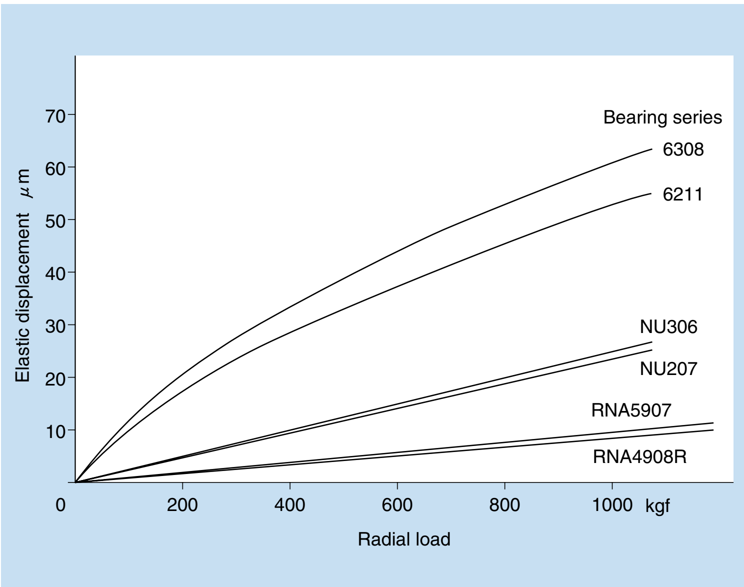

Fig. 1.4

(4) Needle roller bearings are suitable for applications with oscillatory movement.

If the oscillatory movement does not overlap the adjacent rollers, the lubricant between the rollers and bearing ring is pushed out and becomes inadequate. Accordingly, this condition shortens the life of the bearing. To prevent this condition, the bearing must be designed with an oscillatory angle that, at minimum, overlaps the position of the adjacent roller.

This design ensures good lubrication of the adjacent rollers, because the lubricant is forced out of the rollers and prevents them from wearing. **Fig. 1.5** shows the minimum oscillatory angle of the inner and outer rings. This is the most effective means of increasing the number of rollers in one row and ensuring the minimum oscillatory angle. The needle roller bearing is therefore the most suitable for the purpose.

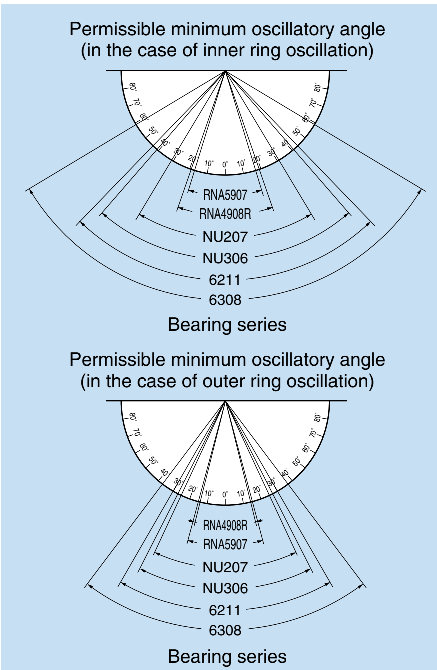

Fig. 1.5

1. 3 Comparison of needle roller and cage assembly bearings and full-complement needle roller bearings

Table 1.1

Item \ Type	Needle roller and cage assembly bearing	Full-complement needle roller bearing
Roller skew	Low incidence	High incidence
Friction coefficient	Small	Large
Temperature rise	Low	High
Permissible speed	High	Low
Load-carrying capacity	Less than that of full-complement needle roller bearings	Can be increased.

Needle roller and cage assembly bearings are used in a wide range of diverse applications, but full-complement needle roller bearings are more suitable for high-load, low-speed, and oscillating applications, as they have a greater load-carrying capacity.

(1) Roller skew

Needle roller and cage assembly bearings feature rotational accuracy due to the ample strength and rigidity of the shaft and bearing housing, which guide the case assembly. This feature ensures the correct rotation of the needle rollers. In contrast, the full-complement needle roller bearing has no structure for precisely guiding the needle rollers, and its instability may cause the needle rollers to skew. (**Fig. 1.6**)

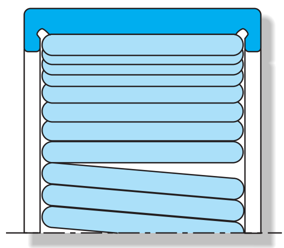

Fig. 1.6

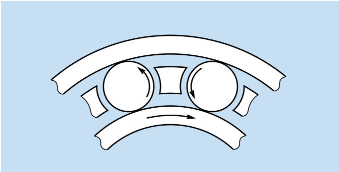
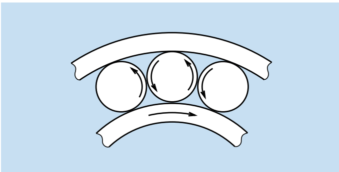
(2) Friction coefficient

Needle roller and cage assembly bearing



The slipping speed between the cage assembly and needle rollers is only the circumference speed of the needle rollers.

Full-complement needle roller bearing



The relative slippage speed of adjacent needle rollers is twice the circumference speed of one needle roller; in addition, skew makes the needle roller rotate while slipping.

Accordingly, the friction coefficient of the full-complement needle roller bearing is about twice that of the needle roller and cage assembly bearing.

Table 1.2 shows the friction coefficient of various types of bearings.

Table 1.2 Friction coefficients of various bearings

Bearing classification	Friction coefficient μ
Deep-groove ball bearings	0.0010～0.0015
Angular contact ball bearings	0.0012～0.0018
Self-aligning ball bearings	0.0008～0.0012
Cylindrical roller bearings	0.0010～0.0015
Tapered roller bearings	0.0017～0.0025
Self-aligning roller bearings	0.0020～0.0025
Thrust ball bearings	0.0010～0.0015
Needle roller and cage assembly bearings	0.0020～0.0030
Full-complement needle roller bearings	0.0040～0.0050
Thrust needle roller bearings	0.0030～0.0040

(3) Temperature rise

The approximate temperature rise of a running bearing is usually calculated with the following formula:

where,

$$T_m - T_0 = 0.00514 \frac{\mu \cdot F_r \cdot d \cdot n}{W_s}$$

T_m : Temperature when the bearing reaches equilibrium ˚C
T_0 : Ambient air temperature ˚C
μ : Friction coefficient
F_r : Radial load kgf
d : Single bore diameter of bearing mm
n : Revolutions per minute rpm
W_s : Heat dissipated to the surroundings per 1˚C temperature difference. Watt / ˚C

(The temperature rise is less with needle roller and cage assembly bearings, as it is proportional to μ.)

Fig. 1.7 shows the effect of changing speed and load on needle roller and cage assembly bearings and full-complement needle roller bearings having the same boundary dimensions for bore diameter (32 mm), outside diameter (47 mm), and width (20 mm).

At 750 kgf and 7500 rpm, as shown in the figure, the full-complement needle roller bearing exceeds 170 ˚C and ceases to rotate, while the needle roller and cage assembly bearing remains below 100 ˚C, thus permitting higher speeds.

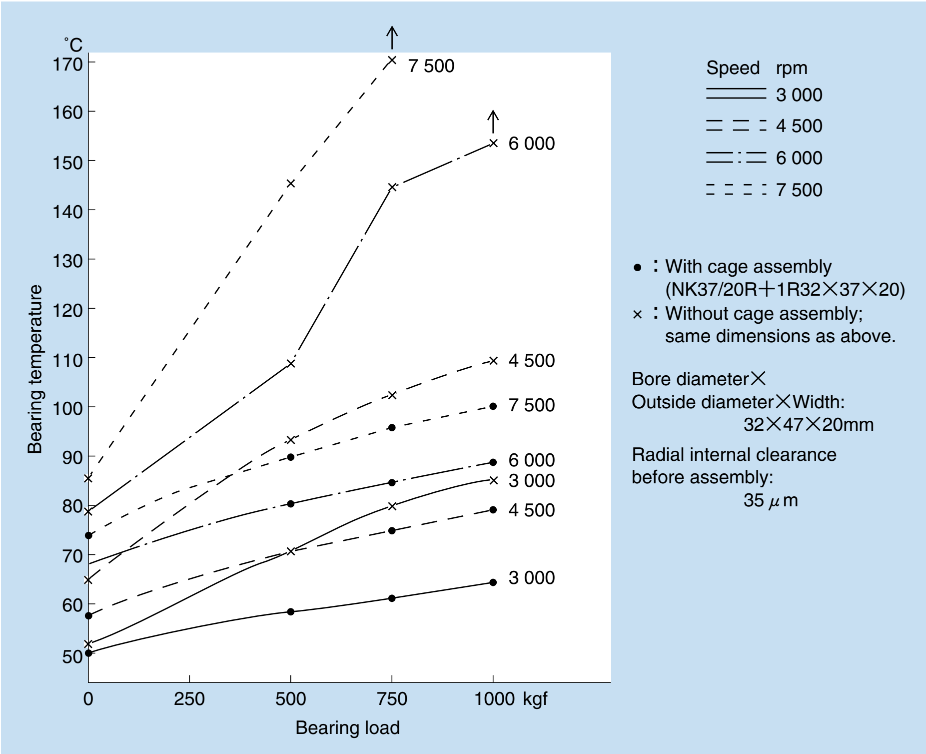


Fig. 1.7

(4) High permissible speeds

According to the characteristics indicated above, needle roller and cage assembly bearings are suitable for high-speed operation. "Permissible speed" is the speed limit that a bearing can safely withstand over a long period. This speed varies with the type and dimensions of the bearing, type of cage assembly, shaft carrying load, lubrication method, peripheral structure around the bearing, and cooling conditions.

The permissible speeds listed in **NTN** catalogs represent the values that can be applied when the bearing is correctly mounted and maintained with the most appropriate lubricant.

(5) Load capacity

The number of rollers in a full-complement needle roller bearing can be increased because there is no cage assembly; therefore, the bearing can be designed with a greater load-carrying capacity.

1

1. 4 Production methods for needle roller bearings

Needle roller bearings (drawn-cup type) are manufactured with the following processes.

The cage shown is a welded type.

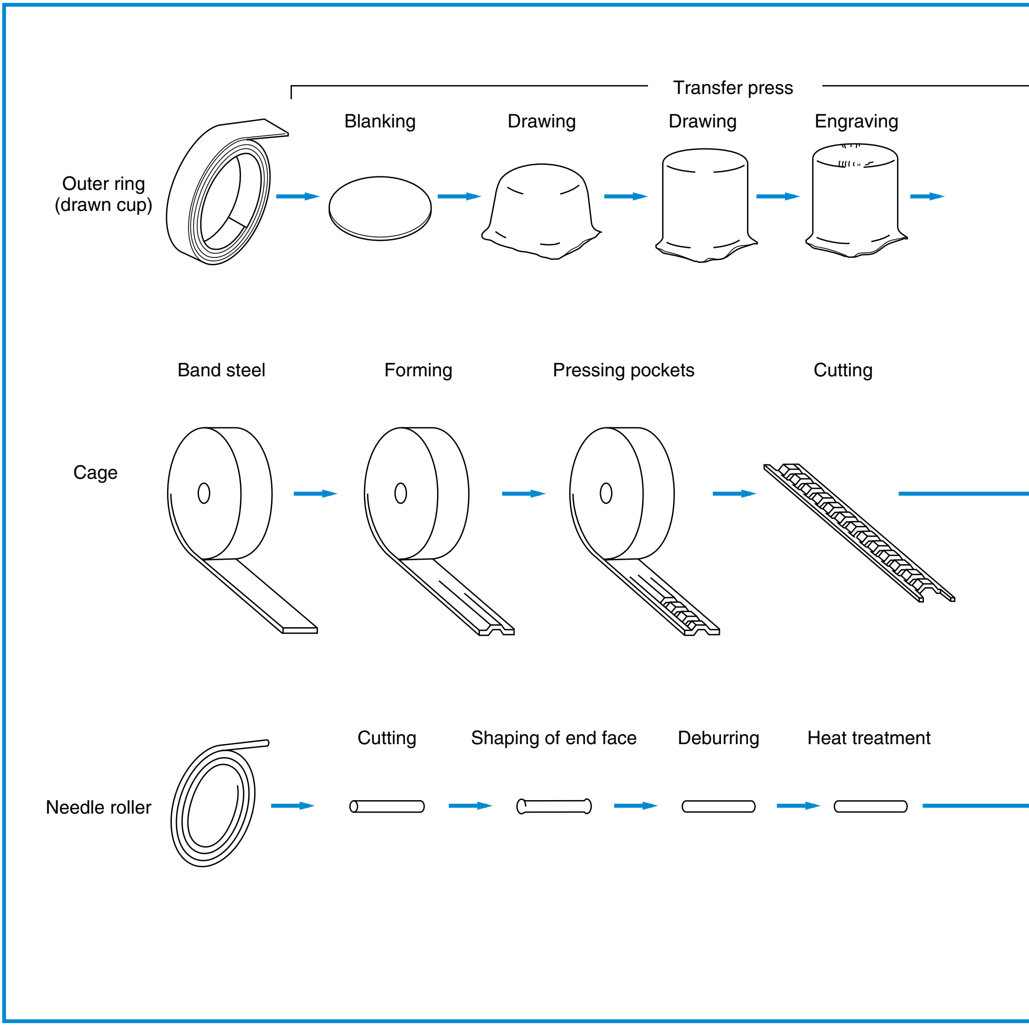

Fig. 1.8 Processing method for drawn-cup needle roller bearings

2. Characteristics of Various Series of Needle Roller Bearings

2. 1 Series numbers and bearing names

Table 2.1 Needle roller and cage assemblies

Category		Series code	Bearing name	Appearance	Characteristics
Needle roller and cage assemblies	Machined-ring type	GH	Cage assembly without roller locating (for crank pins)		H Series, split type
		GK	Needle roller and split cage assembly		K Series, split type
		GPK	Needle roller and split cage assembly (for crank pins)		RK Series, split type Cage assembly with M shaped structure
		H	Cage assembly without roller locating (for crank pins)		High-rigidity cage assembly Capable of higher speeds than the PK Series
		K	Needle roller and cage assembly		Basic type (with high-rigidity cage assembly)
		KBK	Needle roller and cage assembly for piston pins		Bore diameter guide for cage assembly (high-rigidity cage assembly)
		PK	Needle roller and cage assembly for crank pins		Outside diameter guide for cage assembly (high-rigidity cage assembly) Cage assembly with M shaped structure
	Pressed type	KMJ	Needle roller and cage assembly		Steel-plate cage assembly Cage assembly with M shaped structure
		PCJ	Needle roller and cage assembly	↑	Steel-plate cage assembly Cage assembly with M shaped structure Inch series
	Welded type	GK··S	Needle roller and split cage assembly		Thick steel-plate cage assembly High-rigidity cage assembly
		GKV··S	Needle roller and split cage assembly		Thick steel-plate cage assembly
		K··S	Needle roller and cage assembly		Thick steel-plate cage assembly High-rigidity cage assembly
		KJ··S	Needle roller and cage assembly		Steel-plate cage assembly
		KMJ··S	Needle roller and cage assembly		Steel-plate cage assembly Cage assembly with M shaped structure
		KV··S	Needle roller and cage assembly		Thick steel-plate cage assembly High-rigidity cage assembly Cage and assembly with V-shaped structure
		SK··S	Needle roller and single-split cage assembly		K-S Series, single-split type
		SKJ··S	Needle roller and single-split cage assembly		KJ-S Series, single-split type
		SKV··S	Needle roller and single-split cage assembly		KV-S Series, single-split type
	Plastic type	K··T2	Needle roller and cage assembly		Molded cage assembly of polyamide plastic Max. permissible temperature: 120˚C Max. continuous operating temperature: 100˚C

Table 2.2 Machined-ring needle roller bearings

Category		Series code	Bearing name	Appearance	Characteristics
Machined-ring needle roller bearings	With inner ring	MR+MI	Machined-ring needle roller bearings		Inch series Assembly of MR Series and M Series inner rings
		NA 48	Machined-ring needle roller bearing (Dimension series 48)	↑	Assembly of RNA48 Series and IR Series inner rings
		NA 49	Machined-ring needle roller bearing (Dimension series 49)	↑	Assembly of RNA49 Series and IR Series inner rings. Sealed series (L, LL) also available
		NA49··S	Adjustable-clearance needle roller bearing (Dimension series 49)		Assembly of RNA49-S Series and IR Series inner rings
		NA 59	Machined-ring needle roller bearing (Dimension series 59)		Assembly of RNA59 Series and IR Series inner rings
		NA 69	Machined-ring needle roller bearing (Dimension series 69)	↑	Assembly of RNA69 Series and IR Series inner rings
		NAO	Machined-ring needle roller bearings Separable type		Assembly of RNAO Series and IR Series inner rings
		NK+IR	Machined-ring needle roller bearings		Assembly of NK Series and IR Series inner rings
		NKI	Machined-ring needle roller bearings		With inner ring, special
	Without inner ring	MR	Machined-ring needle roller bearings		Inch series High-rigidity outer ring High accuracy, Single-row structure
		NK	Machined-ring needle roller bearings	↑	High-rigidity outer ring High accuracy, Single-row structure
		NKS	Machined-ring needle roller bearings	↑	For heavy loads
		RNA 48	Machined-ring needle roller bearing (Dimension series 48)	↑	High-rigidity outer ring High accuracy, Single-row structure
		RNA 49	Machined-ring needle roller bearing (Dimension series 49)	↑	High-rigidity outer ring High accuracy, Single-row structure Sealed series (L, LL) also available
		RNA49··S	Adjustable-clearance needle roller bearing (Dimension series 49)		Radial clearance is adjustable Single-row structure
		RNA 59	Machined-ring needle roller bearing (Dimension series 59)		High-rigidity outer ring High accuracy, Single-row structure
		RNA 69	Machined-ring needle roller bearing (Dimension series 69)	↑	High-rigidity outer ring, High accuracy Single row ($Fw \leqq 35$), Double row ($Fw \geqq 40$)
		RNAO	Machined-ring needle roller bearings Separable type		High-rigidity outer ring, High accuracy Single-row and double-row series (with ZW) are available
Other items		NKZ	Machined-ring needle roller bearings (with different shape)		Special specifications

Table 2.3 Drawn-cup needle roller bearings-1

Category		Series code	Bearing name	Appearance	Characteristics
Drawn-cup needle rollers	Open-end type	DCH	Drawn-cup needle roller bearing		Inch series With cage assembly, For heavy loading
		DCL	Drawn-cup needle roller bearing	↑	Inch series, With cage assembly
		HK	Drawn-cup needle roller bearing		Double-row type (with ZW) bearings with cage assembly are available Small-diameter plastic bearings (with T2) are available
		HK··L LL	Drawn-cup needle roller bearing Sealing type		With cage assembly Prelubricated with standard grease (3A)
		HKS	Drawn-cup needle roller bearing		With cage assembly, Special
		HMK	Drawn-cup needle roller bearing	↑	With cage assembly, For heavy loading
		HMK··L LL	Drawn-cup needle roller bearing Sealing type		With cage assembly Prelubricated with standard grease (3A)
		HMV	Drawn-cup needle roller bearing		Full-complement needle roller type
		HR	Drawn-cup cylindrical roller bearing		With cage assembly, For heavy loading
		HV	Drawn-cup needle roller bearing		Full-complement needle roller (with C end face rollers)
		HVS	Drawn-cup needle roller bearing	↑ as well 	Full-complement needle roller type Special Prelubricated with standard grease (3A)
		VS	Drawn-cup needle roller bearing		Full-complement needle roller (with C end face rollers)
		VSH	Drawn-cup needle roller bearing	↑	Full-complement needle roller (with C end face rollers) For heavy loading
	Closed-end type	BK	Drawn-cup needle roller bearing		Double-row type (with ZW) bearings with cage assembly are available Small-diameter plastic bearings (with T2) are available
		BK··L	Drawn-cup needle roller bearing Sealing type		With cage assembly Prelubricated with standard grease (3A)
		BKS	Drawn-cup needle roller bearing		With cage assembly
		BMK	Drawn-cup needle roller bearing	↑	With cage assembly
		BV	Drawn-cup needle roller bearing		Full-complement needle roller type
		BVS	Drawn-cup needle roller bearing	↑ as well 	Full-complement needle roller type Prelubricated with standard grease (3A)

Table 2.6 Roller followers

Category	Series code	Bearing name	Appearance	Characteristics
Roller followers	NA22··LL	Roller followers (Sealed type) (Dimension series 22)		With inner ring/cage assembly Prelubricated with standard grease (3A)
	NAB2	Roller followers (Sealed type) (Dimension series 2)		With inner ring/cage assembly (Open type)
	NABR	Roller followers		With inner ring/cage assembly (Equivalent to IKO, NAST)
	NACV··X	Roller followers		Inch series full-complement rollers/non-separable (Equivalent to McGill, CYR) Outside surface of outer ring is cylindrical Prelubricated with standard grease (3A)
	NACV··XLL	Roller followers (Sealed type)		Inch series full-complement rollers/non-separable Outside surface of outer ring is cylindrical Prelubricated with standard grease (3A)
	NATR	Roller followers		With cage and assemblies/non-separable
	NATR··LL	Roller followers (Sealed type)		With cage and assemblies/non-separable Prelubricated with standard grease (3A)
	NATV	Roller followers		Full-complement rollers/non-separable Prelubricated with standard grease (3A)
	NATV··LL	Roller followers (Sealed type)		Full-complement rollers/non-separable Prelubricated with standard grease (3A)
	NUTR2	Roller followers (Dimension series 2)		With double-row cylindrical rollers (Full-complement rollers) / non-separable shield plate Prelubricated with standard grease (3A)
	NUTR3	Roller followers (Dimension series 3)	↑	With double-row cylindrical rollers (Full-complement rollers) / non-separable shield plate Prelubricated with standard grease (3A)
	NUTW2	Roller follower with outer ring and center rib (Dimension series 2)		With double-row cylindrical rollers (Full-complement rollers) / non-separable shield plate Prelubricated with standard grease (3A)
	RNA22··LL	Roller followers (Sealed type) (Dimension series 22)		Without inner ring, with cage and assembly Prelubricated with standard grease (3A)
	RNAB2	Roller followers (Dimension series 2)		Without inner ring (open type), with cage and assembly

Remarks: 1. The external surface of the outer ring is spherical as standard. If a cylindrical outside surface is required, add "X" to the bearing series code.
(Allowance of outside diameter D; Manufactured to JIS Class 0.)
Example: NA2203XLL······
2. The outer surface of the outer ring of the NACV--X(LL) type is cylindrical as standard.
If a spherical outside surface is required, delete the "X" from the bearing series code.
Example: NACV12······

Table 2.7 Cam follower

Category	Series code	Bearing name	Appearance	Characteristics
Cam follower	CR	Cam follower		Inch series, With cage assembly
	CRV··X	Cam follower		Inch series full-complement rollers Outside surface of outer ring is cylindrical Prelubricated with standard grease (3A)
	CRV··XLL	Cam follower (Sealed type)		↑
	KR	Cam follower		With cage assembly Small-diameter plastic type (with T2) is available
	KR··H	Cam follower (with hexagonal hole)		↑ Shaft end (at head side) with hexagonal hole
	KR··LL	Cam follower (Sealed type)		With cage assembly Prelubricated with standard grease (3A)
	KRT	Cam follower (with tap hole)		With cage assembly
	KRU	Cam follower (Eccentric-shaft type)		With cage assembly Eccentricity: 0.25 to 1.0 mm
	KRV	Cam follower		Full-complement needle roller type Prelubricated with standard grease (3A)
	KRV··LL	Cam follower (Sealed type)		↑
	KRVT	Cam follower (with tap hole)		↑
	KRVU	Cam follower (Eccentric-shaft type)		↑ Eccentricity: 0.25 to 1.0 mm
	KRX	Cam follower		Special
	NUKR	Cam follower		Double-row cylindrical rollers (Full-complement rollers) Prelubricated with standard grease (3A)
	NUKRT	Cam follower (with tap hole)		↑
	NUKRU	Cam follower (Eccentric-shaft type)		↑ Eccentricity: 0.4 to 2.5 mm

Remarks: 1. The external surface of the outer ring is spherical as standard. If a cylindrical outside surface is required, add "X" to the bearing series code.
(Allowance of outside diameter D; Manufactured to JIS Class 0.)
Example: KR22XLL······
2. If a spherical outside surface is required for the CRV-X (LL) type, which has a cylindrical outside surface of the outer ring as standard, delete the "X" from the bearing series code.
Example: CRV96······
3. If a hexagonal hole is required at the shaft end, add "H" to the bearing series code.
Example: KRV12H······

Table 2.8 Bearings for linear motion

Category		Series code	Bearing name	Appearance	Characteristics
Bearings for linear motion	Linear ball bearings	KD	Linear ball bearings Stroke type (open type)		High-rigidity, high-accuracy outer ring Limited reciprocating motion
		KD··LL	Linear ball bearings Stroke type (sealed type)		↑ Prelubricated with standard grease (3A)
		KDX	Linear ball bearings		Special
		KH	Linear ball bearings Drawn-cup type		Outer ring of steel plate; lightweight and compact design Ball rows rotate, with unlimited linear motion
		KLM	Linear ball bearings Machined-ring type		High-rigidity, high-accuracy outer ring Ball rows rotate, with unlimited linear motion
		KLM··LL	Linear ball bearings Machined-ring type (Sealed type)		↑ Prelubricated with standard grease (3A)
		KLM··S	Linear ball bearings Machined-ring type (Adjustable-clearance type)	 KLM-S KLM-P	Radial clearance is adjustable
		KLM··P	Linear ball bearings Machined-ring type (open type)		A fan-shaped part of the bearing is removed (in the axial direction) Obstacles such as the shaft support can pass through the bearing
	Linear flat rollers	BF	Linear flat rollers		Cage and assembly of pressed steel Unit length: 1000 mm
		FF	Linear flat rollers		Molded cage assemblies of polyamide plastic
		FF··ZW	Linear flat rollers (Double-row type)		↑ Cage assemblies can be mounted on the bent-V-shaped surface
		RF	Linear flat rollers		↑ Unit length: 705 mm
	Linear roller bearings	RLM	Linear roller bearings		The row of cylindrical rollers rotates in unlimited linear motion. To mount the bearing, secure the bearing by using the threaded holes provided on the reference surface.

Remarks: The standard lengths of BF and RF Series linear flat rollers are specified.
If a special length is required, add the length after the bearing series code.
Example: If the total length L_1 of BF3020 must be 500 mm, indicate it as BF3020/500.

Table 2.9 Other items, Components-1

Category		Series code	Bearing name	Appearance	Characteristics
Other items, Components	Bearing rings	IR	Inner ring		Machined-ring type provides high rigidity and high accuracy (Outside surface is used as raceway surface)

		CRP	Stud		Shaft for Series CRZ assembly
		CRS	Side roller unit		Bearing for Series CRZ assembly (inside) Prelubricated with standard grease (8A)
		CRZ	Cross roller		For truck lifts Assembly, prelubricated with standard grease (8A)
	Other items	BU	Bushing		Special specifications (mainly for spacers)
		HKZ	Drawn-cup needle roller bearing of different shape		Special product using drawn-cup needle roller bearings
		HSF	Bearing for steering		With inner and outer bearing rings of steel plate and steel balls Prelubricated with standard grease (2S)
		HSL	Drawn-cup double-row cylindrical roller bearing		Full-complement roller, for heavy loading, outer ring of steel plate, machined inner ring, prelubricated with standard grease (3A)
		NIP	Grease nipple		For cam followers (Press fitting, mounted with screws)
		SEN	Plug		Grease nipples provided on unlubricated side
		TKBN	Components		Components not meeting standards of needle bearing series
		PNA	Self-aligning needle roller and cage assembly bearing		With inner ring. Self-aligning model available
		RPNA	Self-aligning needle roller and cage assembly bearing		Without inner ring. Self-aligning model available

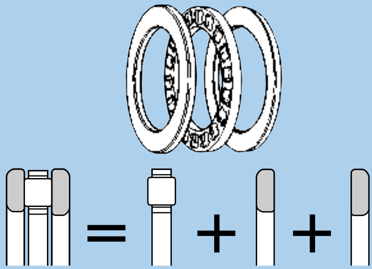
Tips & Hints

●Thrust roller bearings

Two categories of thrust roller bearings exist: assembled needle roller bearings and assembled cylindrical roller bearings.

They are assembled with bearing washers before use. The cylindrical roller bearing group comprises of a cylindrical roller and thrust cage assembly (K811, K812 and K893 Series), inner ring (WS Series), and outer ring (GS Series); bearings that combine these components are available (811, 812 and 893 Series).

Customers can either purchase an assembled bearing or purchase the components separately and assemble them as required.



The shaft aligns with the single bore diameter for WS Series bearing rings and the housing aligns with the outside surface for GS Series bearing rings; therefore, they feature high rigidity and accurate running.

Fig. 1 Assembly example

Bearing assembly	Assembly drawing	Assembly of thrust cage assemblies	Bearing ring (inner ring)	Bearing ring (outer ring)
———		AXK11	AS811	AS811
———		AXK11	WS811	GS811
811		K811	WS811	GS811
812		K812	WS812	GS812
874		K874	WS874	GS874
893		K893	WS893	GS893

●Machined-ring needle roller bearings

Machined-ring needle roller bearings are available in two categories: RNA Series without an inner ring and NA Series with an inner ring. All components are common except the inner ring, as follows.

Example:

RNA4905R+IR25×30×17···/NA4905R

Accordingly, it is possible to purchase the RNA and IR separately and assemble them as needed. Note that the separable RNAO Series without an inner ring and NAO Series with an inner ring have common model numbers, except for the inner ring.

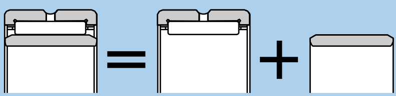


Fig. 2 Assembly example

3. Bearing Selection

Table 3.1 shows the types and characteristics of needle roller bearings.

Needle roller bearings are available in a wide range of varying dimensions. Selecting a particular bearing requires a thorough knowledge of the structure and characteristics of different bearings and their correct applications. No bearing, no matter how well made, will achieve its full potential if not carefully selected and correctly used. When selecting bearings, consider the following points.

Table 3.1 Classifications and characteristics of bearings

Category / Items	Needle roller and cage assemblies	Needle roller and cage assembly bearing	Separable needle roller and cage assembly bearing	Adjustable-clearance needle roller bearing	Drawn-cup needle roller bearing	Needle roller bearing with thrust ball bearing	Needle roller bearing with thrust cylindrical roller bearing	Needle roller bearing with angular contact ball bearing

4. Load Rating and Life

4. 1 Bearing life

Even in bearings operating under normal conditions, the surfaces of the raceway and rolling elements are constantly subjected to repeated compressive stresses that cause flaking of these surfaces. This flaking is due to material fatigue and eventually causes bearing failure. The effective life of a bearing is normally defined as the total number of revolutions a bearing can undergo before flaking occurs on either the raceway surface or the rolling element surfaces.

4. 2 Basic rated life and basic dynamic load rating

If a group of seemingly identical bearings is subjected to identical load and operating conditions, they will exhibit a wide diversity in their durability. This can be attributed to the difference in the fatigue of the bearing material itself. This disparity is statistically monitored, and the basic rated life is expressed as "the total number of revolutions that 90% ('90% reliability') of the bearings in an identical group of bearings subjected to identical operating conditions will attain or surpass before flaking due to material fatigue occurs." For bearings operating at constant fixed speeds, it is expressed as the total number of hours of operation.

The basic dynamic load rating is an expression of the load capacity of a rolling bearing and can be described as the constant load under which a bearing can sustain a basic rated life of one million revolutions. For radial bearings it refers to pure radial loads; for thrust bearings it refers to pure axial loads.

The relationship between the basic rated life, basic dynamic load rating and bearing load is given in formula (4.1).

$$L_{10}=\left(\frac{C}{P}\right)^{p} \cdots\cdots\cdots\cdots (4.1)$$

where,

p=10/3 ·········For roller bearings

p=3 ···············For ball bearings

L_{10}: Basic rated life of 10^6 revolutions

C : Basic dynamic rated load N {kgf}

Radial bearings: C_r

Thrust bearings: C_a

P : Bearing load N {kgf}

Radial bearings: P_r

Thrust bearings: P_a

The basic rated life can also be expressed in terms of hours of revolution, and is calculated as shown in formula (4.2).

$$L_{10h}=\frac{10^6}{60n}\left(\frac{C}{P}\right)^{p} \cdots\cdots\cdots\cdots (4.2)$$

where,

L_{10h}: Basic rated life h

n : Rotational speed, rpm

4. 3 Factors affecting bearing life

Apart from bearing load and revolution speed, the factors affecting bearing life include lubricating conditions, internal clearance, roughness of raceway surface, hardness, heat treatment (structure), and installation errors (misalignment). Consider all these factors when using bearings. For details, refer to the relevant catalog.

Table 4.1 Outline of bearing operating conditions

Permissible revolutions (N)	Refer to catalog values Note: When lubricating, $F_w \cdot n \leqq 40\times10^4$ rpm F_w: Roller set bore diameter
Roughness of raceway surface	Within 0.4a (Rmax 1.6 μm)
Hardness of raceway surface	HRC58-64 Note: Refer to Section 6.3 for materials and heat treatment hardness.
Installation error	Less than 1/2 000
Radial internal clearance	Normal (C2, C3, C4)

4. 4 Installation error and crowning

It is well known that bearing life can be dramatically reduced due to stress concentration at the roller ends (edge load) caused by installation error. "Roller crowning" is employed as a countermeasure to this problem. However, this may reduce the effective contact length of the rollers and reduce the bearing life unless a proper design is made. Installation error and loading conditions may require calculation of the proper crowning value. **Figs. 4.1** to **4.3** show examples of analyses of the contact face pressure according to the computer calculation for reference.

Figs. 4.1 to **4.3** (examples of analyses of contact face pressure) show that the rollers without crowning provide higher edge face pressure, but the rollers with crowning are limited to lower edge face pressure in the range of constant installation error. **Fig. 4.4** shows the relationship (example of computer analysis) between installation error and bearing life. The figure shows the influence of installation errors on the bearing life.

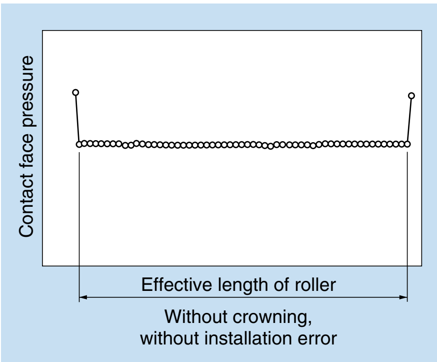

Fig. 4.1

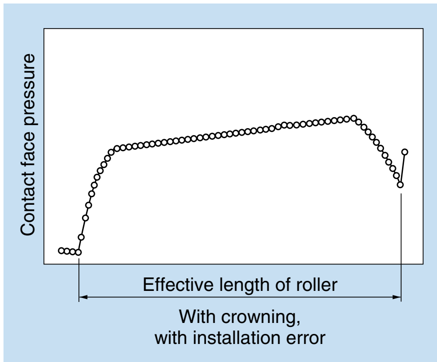

Fig. 4.2

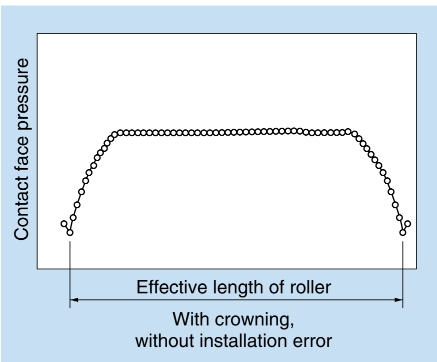

Fig. 4.3

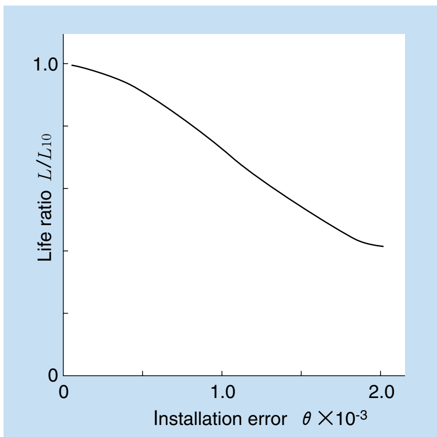

Fig. 4.4 Relationship between installation error and bearing life

4. 5 Radial internal clearance, surface roughness, surface hardness and bearing life

Fig. 4.5 shows the relationship between radial internal clearance and bearing life.

Fig. 4.6 shows the relationship between surface roughness and bearing life.

Fig. 4.7 shows the relationship between surface hardness and bearing life.

The following figures show factors affecting bearing life.

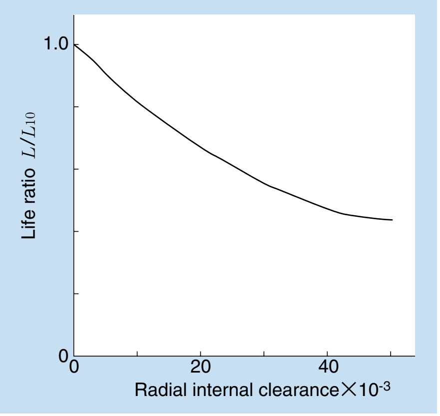

Fig. 4.5 Relationship between radial interna clearance and bearing life

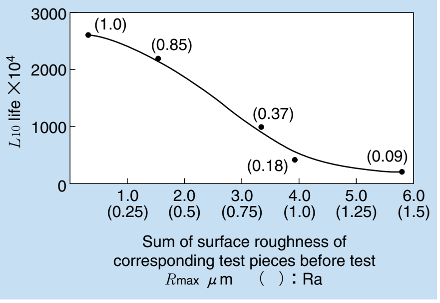

Fig. 4.6 Relationship between surface roughness and life

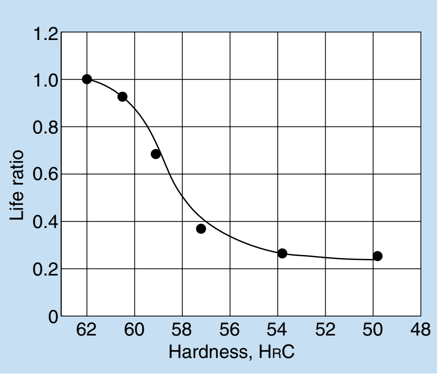

Fig. 4.7 Influence of hardness on rolling fatigue life

4. 6 Tips for longer bearing life

To increase the life of needle roller bearings, special heat treatment (AS treatment) has been applied to double or even triple the life compared to the standard product, as determined by bench tests. Moreover, a high oil-film formation capability has been achieved through a recently developed surface-processing technology known as the HL process. As a result, a longer life effect is observed in the areas where surface damage at starting points easily occurs. This development has been well received in the market. For details, refer to catalogs and references.

4. 7 Basic static load rating

When bearings are subjected to loads, they suffer from partial permanent deformation of the contact surface between the rolling elements and the bearing ring. The deformity increases as the load increases, and if this increase in load exceeds certain limits, smooth operation of the bearings is subsequently impaired. Experience has revealed that a total permanent deformity of 0.0001 times the diameter of the rolling element -- occurring at the center of the most heavily stressed contact point between the raceway and the rolling elements -- can be tolerated without any impairment in running efficiency. The basic static load rating refers to the fixed static load limit at which a specified amount of permanent deformation occurs. It represents pure radial loads for radial bearings and pure axial loads for thrust bearings. These values are listed in the bearing dimensions table. They are listed in the C_{or} column for radial bearings and in the C_{oa} column for thrust bearings. The contact stresses occurring at the center of the rolling element and raceway contact points under the maximum load are given below.

Roller bearings ···4000 MPa (408 kgf/mm^2)
Ball bearings ······4200 MPa (428 kgf/mm^2)

Generally, the permissible static equivalent load is limited by the basic static load rating. However, depending on the requirements for smooth operation and friction of revolution, these limits may be greater or lesser than the basic static rated load.

In the following formula (4.3) and **Table 4.2**, the maximum static equivalent load can be determined with consideration for the safety factor S_o.

Table 4.2 Minimum safety factor S_o

Operating conditions	Roller bearing	Ball bearing
Demand for high rotational accuracy	3	2
Demand for normal rotating accuracy (Universal application)	1.5	1

Remarks 1. For thrust roller bearings using the drawn-cup needle roller bearing and pressed thrust washer, the minimum S_o value should be 3.
2. When vibration and/or shock loads are present, a load factor based on the shock load must be included in the P_o max value.

$$S_o = \frac{C_o}{P_{o\,\max}} \cdots\cdots\cdots\cdots\cdots\cdots (4.3)$$

where,

S_o : Safety factor
C_o : Basic static rated load N {kgf}
Radial bearings: C_{or}
Thrust bearings: C_{oa}

P_o max:
Maximum static equivalent load N {kgf}
Radial bearings: P_{or} max
Thrust bearings: P_{oa} max

5

5. Fitting Needle Roller Bearings

5. 1 Fitting machined-ring radial needle roller bearings

The inner and outer rings of needle roller bearings are separable. Both inner and outer rings can be mounted with a given interference, but in the case of a tight fit, the bearing ring subjected to static loads can be provided with a loose fit, considering the ease of mounting and removal of the bearing.

Table 5.1 shows the bearing fit according to a given load.

Table 5.2 shows the recommended fits for radial needle roller bearings (machined ring, with inner rings). However, the interference may be reduced due to temperature increase or surface roughness of fitting surfaces. In this case, refer to the relevant catalogs for details.

Table 5.1 Characteristics and fittings of radial loads

Illustration	Rotation type	Load type	Fitting
Static load 	 Rotating inner ring Stationary outer ring	Rotating inner ring load Stationary outer ring load	Inner ring : Tight fit Outer ring: Loose fit
Unbalanced load 	 Stationary inner ring Rotating outer ring		
Static load 	 Stationary inner ring Rotating outer ring	Stationary inner ring load Rotating outer ring load	Inner ring : Loose fit Outer ring: Tight fit
Unbalanced load 	 Rotating inner ring Stationary outer ring		

Table 5.2 Fitting of needle roller bearings

Table (a) Axial allowance

Conditions			Tolerance range class
Load type	Load size	Shaft diameter d mm	
Rotating inner ring load or indeterminate direction load	Light loads	～ 50	j5
	Normal loads	～ 50	k5
		50～150	m5
		150～	m6
	Heavy loads and shock loads	～150	m6
		150～	n6
Stationary inner ring load	Medium/low revolutions, light loads	All shaft diameters	g6
	General applications		h6
	When high accuracy is required		h5

Table (b) Housing allowance

Conditions		Tolerance range class
Stationary outer ring load	Normal and heavy loads	J7
	Normal load with double split housing	H7
Rotating outer ring load	Light loads	M7
	Normal loads	N7
	Heavy loads and shock loads	P7
Indeterminate loads	Light loads	J7
	Normal loads	K7
	Heavy loads and shock loads	M7
When high rotational accuracy is required with light loads		K6

Remarks: For classifications of light loads, normal loads, and heavy loads, refer to the following values:
Light load $Pr \leqq 0.06Cr$
Normal load $0.06Cr < Pr \leqq 0.12Cr$
Heavy load $Pr > 0.12Cr$

5. 2 Fitting of drawn-cup needle roller bearings

The dimensional accuracy of drawn-cup needle bearings is guaranteed when the standard ring is used because they are designed to correct the deformation by press fitting in the housing hole and their specified dimensional accuracy is assured. Refer to the relevant catalog for the dimensional allowances of roller set bore diameter when press-fitting the standard ring.

Table 5.3 shows the recommended fits of bearings.

Table 5.3 Fitting of housing and shaft

Bearing series	Housing		Shaft	
	Ferric group	Light alloy	Without inner ring	With inner ring
HK, BK	N6 (N7)	R6 (R7)	h5 (h6)	k5 (j6)
HMK, DCL	J6 (J7)	M6 (M7)		
HCK	F7	—	k6	—

The method for examining internal clearance during fitting of drawn-cup needle roller bearings is described on the next page for reference. If the housing material is a light alloy, care should be taken in consideration of reduced interference due to temperature increase.

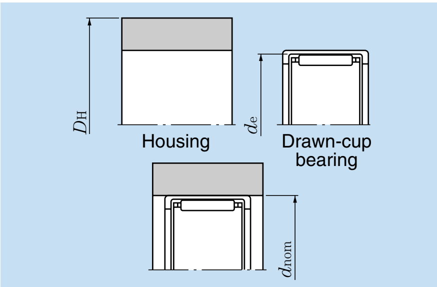
5

5. 3 Examination of contraction ratio and clearance after mounting

Recommended fits of standard products are listed in catalogs. The calculation method is also provided in detailed examination to be carried out.

1) Calculation of bearing contraction ratio

If a drawn-cup bearing is used, the contraction ratio is calculated as shown in the formula.



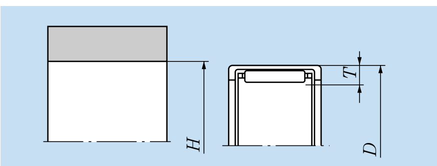
$$\lambda = \frac{2t}{E_2} \cdot \frac{1-S^2}{\frac{(0.7S^2+1.3)(1-t^2)}{E_1} + \frac{(0.7+1.3t^2)(1-S^2)}{E_2}} \quad \cdots\cdots\cdots\cdots (1)$$

λ : Outer ring contraction ratio
D_H : Housing single outside diameter mm
d_{nom} : Nominal diameter of fitting section mm
d_e : Diameter of rolling contact surface of the outer ring mm
E_1 : Young's modulus of housing kgf/mm²
E_2 : Young's modulus of outer ring (21 200 kgf/mm²)

$$S = \frac{d_{nom}}{D_H} \qquad t = \frac{d_e}{d_{nom}}$$

2) Setting bore diameter after fitting the actual housing

① Press fitting of standard ring



H : Housing bore diameter mm
T : Roller diameter + plate thickness mm
D : Drawn-cup bearing single outside diameter mm
L_i : Roller set bore diameter after press fitting mm

When the standard ring is press-fit, the dimensions of the roller diameter plus the plate thickness do not change. Accordingly, the roller set bore diameter, L_i, is as follows:

$$L_i = D - 2T - \lambda(D-H) = (1-\lambda)D - 2T + \lambda H \cdots (2)$$

The mean value and standard deviation of the "roller diameter + plate thickness" (=T) can be calculated by the formula (2). The mean value given by formula (2) is:

$$m_{Li} = (1-\lambda)m_D - m_{2T} + \lambda m_H \cdots\cdots\cdots\cdots (3)$$

Standard deviation of formula (2) is:

$$\sigma_{Li}^2 = (1-\lambda)^2 \cdot \sigma_D^2 + \sigma_{2T}^2 + \lambda^2 \sigma_H^2 \cdots\cdots (4)$$

In the case of the standard ring, because $\sigma H^2 = 0$, formula (4) is:

$$\sigma_{Li}^2 = (1-\lambda)^2 \cdot \sigma_D^2 + \sigma_{2T}^2 \quad \cdots\cdots\cdots (5)$$

Unknown values in formula (3) and (5) are only m_{2T} and σ_{2T}^2. Accordingly, substitute known numerical values for (3) and (5) to obtain m_{2T} and σ_{2T}^2.

② For press fitting of the actual housing, consider the same method as the standard ring press fitting.

Here, terms for press fitting of the actual housing are identified with an apostrophe (') for classification/clarification.

$$m_{Li'} = (1-\lambda')m_D - m_{2T} + \lambda' m_{H'} \cdots\cdots\cdots\cdots (6)$$

$$\sigma_{Li'}^2 = (1-\lambda')^2 \cdot \sigma_D^2 + \sigma_{2T}^2 + \lambda'^2 \sigma_{H'}^2 \cdots (7)$$

③ Previously calculated values are substituted for m_{2T} and σ_{2T}^2 in formulas (6) and (7).

④ The roller set bore diameter, L_i', for press fitting the actual housing can be calculated by the following formula.

$$L_i' = m_{Li'} \pm 3\sigma_{Li'} \quad \cdots\cdots\cdots\cdots (8)$$

⑤ To calculate the radial internal clearance, consider the mean value and standard deviation of the shaft in formulas (6) and (7).

⑥ The target value of radial internal clearance is usually set so that the normal clearance can be obtained. However when used for motor vehicles, recommended values are indicated for the respective components. For details, consult **NTN**.

6. Shaft and Housing Design

6. 1 Shaft and housing accuracy

Because the bearing rings of needle roller bearings are so thin, the accuracy of the surfaces of the shaft and housing in which the bearing is mounted has a considerable effect on the accuracy of the raceways.

Under normal conditions of use, a turned finish is adequate for mating surfaces. However, if a heavy load rating, noise reduction, or high precision are required, a ground finish is necessary.

Table 6.1 shows the dimensional accuracy of the fitting face between the shaft and housing, the shape accuracy, the surface roughness, and the shoulder perpendicularity against the fitting face under normal operating conditions.

With split-type housings, if a grinding undercut is made on the inside diameter of the mating surface, distortion of the outer ring is prevented when the housing is assembled.

Table 6.1 Shaft and housing accuracy

Characteristic		Shaft	Housing
Dimensional accuracy		IT6 {IT5}	IT7 {IT6}
Circular deviation Cylindrical deviation	(Maximum)	IT3 {IT2}	IT4 {IT3}
Shoulder perpendicularity (Maximum)		IT5 {IT4}	IT5 {IT4}
Roughness of fitting surface		0.8a	1.6a

Note: Bearings with an accuracy exceeding Class 5 appear within brackets.

6. 2 Raceway accuracy

A shaft and housing are often used directly in place of needle roller bearings with raceways. To regulate the radial internal clearance to the specified allowance and ensure high revolution accuracy, the dimensional accuracy, shape accuracy, and surface roughness of the raceway must be equivalent to that of the raceway surface of the bearing. **Table 6.2** shows the accuracy and surface roughness of the raceway surface.

Table 6.2 Accuracy of raceway surface

Characteristic		Shaft	Housing
Dimensional accuracy		IT5 {IT4}	IT6 {IT5}
Circular deviation Cylindrical deviation	(Maximum)	IT3 {IT2}	IT4 {IT3}
Shoulder perpendicularity (Maximum)		IT3 {IT2}	IT3 {IT2}
Axial runout (Maximum) Thrust bearing		IT5 {IT4}	
Surface roughness		Within 0.4a (R_{max}1.6 μm)	

Remarks: Components with high rotational accuracy appear in brackets.

6. 3 Raceway materials and their hardness

When the single outside diameter or single bore diameter of a shaft or housing is used in place of a raceway, the surface hardness should be HRC58 to HRC64 in order to maintain sufficient load-bearing capacity. In this case, the types of materials shown in **Table 6.3** should be used following suitable heat treatment.

When raceways have been hardened by carburization or induction, the hardness penetration is defined as the adequate depth of a hardened surface layer with a hardness of HV550 when measured from the surface. The minimum depth of hardness can be calculated according to Formula 6.1.

$$E_{ht\,\min} \geqq 0.8D_W\,(0.1+0.002D_W) \cdots\cdots (6.1)$$

where,

$E_{ht\,\min}$: Minimum hardness adequate depth mm

D_W : Roller diameter mm

Table 6.3 Raceway materials and their hardness

Steel type	Code	Standard
High carbon chromium bearing steel	SUJ2	JIS G 4805
Carbon tool steel	SK3	JIS G 4401
Nickel chromium molybdenum steel	SNCM420	JIS G 4103
Chromium steel	SCr420	JIS G 4104
Chromium molybdenum steel	SCM420	JIS G 4105
Nickel chromium steel	SNC420	JIS G 4102

7. Tips on Bearing Use

Needle roller and cage assembly bearings have various advantages, yet they also have limitations. Before using these bearings, follow the precautions listed in this section in order to ensure the optimal service life.

(1) Minimal space for lubricant

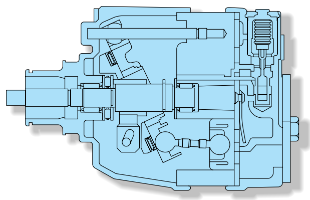
Although a small cross-sectional bearing height is an advantage, this space includes the cage assembly, which leaves very little room available for the lubricant.

In addition, as the cage assembly is guided by either the inner ring or outer ring, the lubrication of these guiding surfaces must be considered.

Accordingly, except in the case of extremely low speed operation, a lubrication hole must be provided for oil lubrication, or, in the case of grease lubrication, adequate maintenance must be ensured through rigid scheduling of lubrication intervals.

(2) Axial loads

Except for a partial grouping, needle roller bearings cannot carry axial loads. Axial loads caused by pure radial loads are generally about 3% to 5% of radial loads, and paying attention to the lubricating surface is normally sufficient. However, if the axial loads act expressly on a bearing, consider the use of thrust bearings.



Tips & Hints

●Guide surface in the axial direction

When a needle roller and cage assembly is used alone and is guided in an axial direction at the shaft shoulder (**Fig. 7.1**), the shaft shoulder surface should have a burr-free, improved finish where it contacts the side face of the cage assembly. In high-speed applications, the contact faces should be hardened and finish-ground. Thrust rings stamped from spring plate with a press are also suitable as axial guides for the cage assembly.

When the cage assembly is guided in an axial direction through the use of a locating snap ring (**Fig. 7.1**), it is recommended that a thrust ring be used between the cage assembly and locating snap ring so that the cut ends of the locating snap ring do not directly contact the cage assembly.

Generally, when a shaft with a radial needle roller bearing is to be positioned in the axial direction, ball bearings or thrust bearings are used to determine the axial direction. However, when the axial direction load is small and the revolution speed is not high (for example, an idler gear in a gear box), mount the thrust ring on the shaft and position the thrust ring by striking it against the outer ring or housing shoulder, as shown in **Fig. 7.2**. In this design, lubrication on the guide surface requires care. **Fig. 7.3** shows an example of a thrust ring with an oil groove processed on the guide surface. This oil groove and the flat part of the shaft must be chamfered and smoothed.

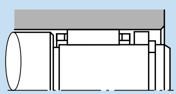


Fig. 7.1

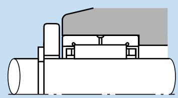

Fig. 7.2

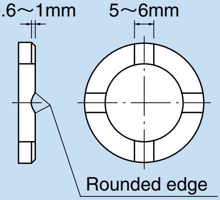

Fig. 7.3 Thrust ring

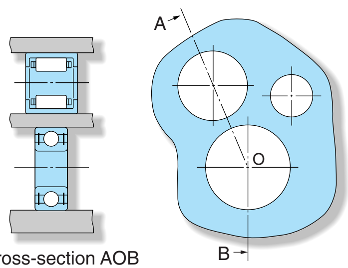
(3) Shape errors

Needle roller and cage assembly bearings have good accuracy and can be rotated at high speed with small internal clearance. The accuracy of the bearing box of the single outside diameter of the shaft or single bore diameter requires special care, because the shaft or housing shapes directly appear on the raceway surface due to the thin materials used for the inner ring or outer ring.

Regarding general housing accuracy, inferior accuracy is found where differences exist in ribs and material thicknesses.

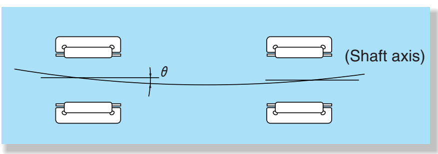
Care should be taken because needle roller bearings used under such conditions contribute to negative clearances and generate large axial loads or result in heating and seizure.



Cross-section AOB

4) Misalignment

Always be careful to keep the axial deflection to less than 1/2 000, as twisting can have a serious effect due to the high rigidity. When the internal clearance is small, or a wide needle roller bearing is used, a particular effort is required to ensure minimal misalignment.

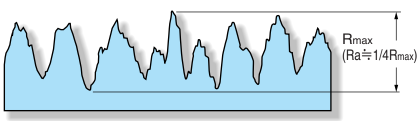


(5) Materials, hardness, and accuracy of the raceway surface

For general bearings, an appropriate bearing steel is used for inner rings, outer rings, and rollers, and a precision finishing process is applied following careful heat treatment. On the other hand, needle roller bearings are also used without inner rings only, or without either inner or outer rings (in other words, the shaft or housing is used in place of raceway surface), to achieve certain advantages.

The basic rated static load listed in catalogs refers to the bearings mentioned above. If the shaft or housing is used in place of a bearing ring, it should comply with the inner and outer rings of the bearing. Consequently, it is necessary to select a flawless steel containing no nonmetals and to produce a surface hardness of HRC 58-64 through careful heat treatment. If only the surface is hardened by carburization, it is recommended that careful attention be paid to ensure that the hardened surface layer has adequate depth and surface hardness.

The roughness of the raceway surface should be in the range of 0.4a ($R_{max} \times 16\ \mu m$), and there should be no winding along the circumference. The roundness and cylindricity should be less than 50% of the dimensional allowance.



8. Engineering Data

8. 1 Track loading capacity of cam followers and roller followers

The track loading capacity is calculated by the relationship between the stress and Hertzian stress by establishing a standard hardness (standard tension stress) with the relationship between the hardness and pure tension stress of the materials. The methods for setting the standard hardness (tension stress) vary slightly by manufacturer, but the accompanying table from the JIS Iron and Steel Handbook (showing approximate values based on the revised conversion table of JIS Z8413) is used to determine the relationship between hardness and tension stress.
HRC40 = σ =127 kgf/mm² is adopted as the standard hardness (tension stress).

(1) Track capacity factor

The tension stress of a material increases as the hardness increases; at the same time, the track loading capacity also increases. In this case, the actual track loading capacity can be calculated by multiplying the track loading capacity with the track capacity factors listed in **Table 8.1**.

Note: The calculated track loading capacity shown above is based on the pure tension stress, but not the permissible Hertzian stress. In general, the stress (corresponding force) causing material creep is greater than the tension stress. With static loads in particular, this track loading capacity is considered a safe value.

Example: If the track capacity with a specific hardness is calculated with the track capacity factor:

When the track loading capacity is C_t, the track capacity factor is A at the subject hardness, and the track loading capacity can be found as follows:

$$C_t' = A \cdot C_t$$

For NATR15X, if the hardness is HRC 50:

C_t =1 220 kgf, A=1 987

$\therefore C_t'$=1 987×1 220=2 424 kgf

(2) References (Calculation of track capacity)

- If the outer ring is cylindrical:

$$\sigma_{max} = 60.9\sqrt{\frac{F_r \Sigma \rho}{B_{eff}}}$$

- If the outer ring is spherical with R:

$$\sigma_{max} = \frac{187}{\mu \nu}\sqrt[a]{(\Sigma \rho)^2 F_r}$$

where,

σ_{max}=127kgf/mm²

F_r : Track loading capacity (kgf)

$\Sigma \rho$: Sum of curvatures

B_{eff} : Effective contact length (mm)

where (outer ring width – 2×chamfer)

55	212	2.787	4.652

8. 2 Outer ring strength

Generally, outer rings do not break under normal operating loads, but the following is calculated as a checkpoint for operations under shock loads and heavy loads.

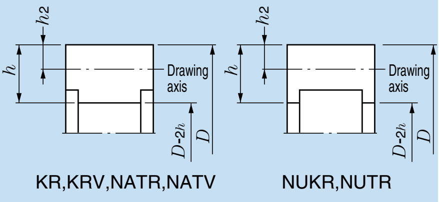

Fig. 8.1

Fig. 8.1 shows outer ring shapes. They are calculated with the following formula. Outer ring breaking strength means the fracture strength of rollers when in a bridge formation.

To determine the fracture strength, generally 180 kgf/mm² can be applied to bearing steel, but we use 120 kgf/mm² as max here in keeping with our own experiences and in consideration of applied concentration. For normal use, the stress is recommended to be less than 20 kgf/mm² and the strength in this case is calculated as follows.

$$P=\frac{4\pi}{1+f(\alpha)}\times\frac{D-2h}{h(D-2h2)^2}\times I\times\alpha \quad \text{(kgf)}$$

$$f(\alpha)=\frac{(\pi-\alpha)\sin\alpha-(1+\cos\alpha)}{2\cos\ \alpha} \quad \text{(rad.)}$$

$$\alpha=\frac{180}{Z} \quad \text{(rad.)}$$

where,

I : Outer ring cross-section secondary moment (mm⁴)

Z : Number of rollers

σ : Breaking stress (kgf/mm²)

P : Breaking load (kgf)

※Use special care if a spring washer is used to lock the screws, as this may reduce the stud strength.

8. 3 Stud strength of cam followers

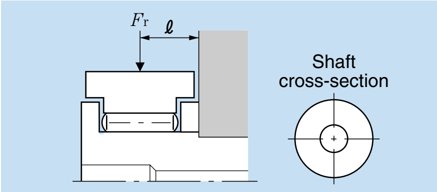

Fig. 8.2

In **Fig. 8.2**, if the load Fr acts at the center of the width of the outer ring, the stud receives the bending moment equivalent to $Fr \times \ell$. Tension stress created on the stud surface by this moment is established as σ_1. Further, the stud itself is tightened with a nut or machine unit, generating tension stress σ_2.

The sum of the tension stresses $\sigma_1+\sigma_2$ must not exceed the material allowance. The recommended tightening torque listed in the catalogs is $\sigma_2 ≒ 10$ kg/mm² for most types.

The stud strength is calculated for all types in this section. However, the spring washer is not used in this case※.

- As shown in the figure, loads should act at the center of the outer ring.
- The shaft cross-section should follow the drawing.
- The permissible stress in each case refers to the following items. The tension stress due to tightening is set as $\sigma_2 ≒ 10$ kg/mm².

Static bending stress σ =140kgf/mm²

Repeating bending stress (pulsating)
σ =100kgf/mm²

Repeating bending stress (alternating)
=40kgf/mm²

$$\sigma_1=\frac{M}{Z}=\frac{Fr\cdot\ell}{Z}$$

where,

$$\sigma_1+\sigma_2=\sigma$$

Z : Shaft section modulus (mm³)

Fr: Load (Stud strength in kgf)

8. 4 Calculating tightening torque of cam follower

The following relationship exists between the screw tightening torque and tightening force.

$$T=\frac{F}{2}\left\{(1.15\mu+\tan\beta)d_2+\mu_w d_w\right\}$$

where,

T : Tightening torque
F : Tightening force
μ : Friction coefficient
μ_w : Nut bearing surface coefficient
β : Lead angle of thread
d_2 : Effective diameter of thread
d_w : Effective diameter between the nut bearing surface and mounting hole (with hexagon nut)

Here, $\mu=\mu_w$=0.15 is assumed.

$d_2=0.92d$

$\tan\beta=P/(\pi\cdot d_2)$

$$d_w=\frac{0.608B^3-0.524D_i^3}{0.866B^2-0.785D_i^2}$$

where,

d : Nominal diameter of thread
P : Thread pitch
B : Width across flat of nut
D_i : Mounting hole bore
$D_i \fallingdotseq d$ is established.

On the other hand, the relationship between the tightening force and tension stress is expressed as follows:

$$\sigma_2=\frac{F}{S}$$

σ_2 : Tension stress
S : Shaft cross-section area

where, σ_2 refers to the setting according to the cam follower stud strength calculation in Section 8.3.

$\sigma_2=10\text{kgf/mm}^2$

$F=S\cdot\sigma_2=S\cdot 10$ {kgf}

The tightening torque is as follows:

$$F=\frac{F}{2}\{(0.1725+\tan\beta)\times 0.92d+0.15d_w\}\times 10^3$$

$$F=\frac{S\cdot 10}{2}\{(0.1725+\frac{P}{0.92d\cdot\pi})\times 0.92d$$

$$+0.15\times\frac{0.608B^3-0.524d^3}{0.866B^2-0.785d^2}\}\times 10^3 \ \{\text{kgf-m}\}$$

9. Product Introduction & Index

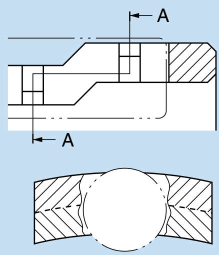
Needle roller and welded cage assemblies with large diameters

We developed needle bearings for idlers in the transmissions of large vehicles. Conventional welded cage assemblies have been difficult to use in this application.

■ Features

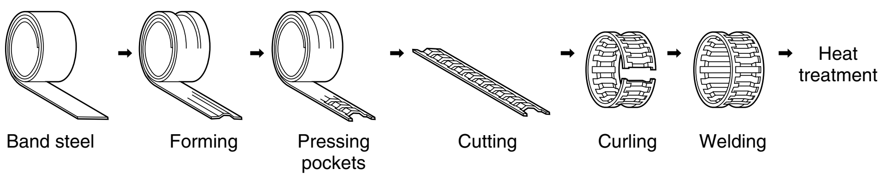
1) The use of a plate thicker than the former welded cage assembly improves the strength of the cage assembly.
2) Ensures a stable roller guide surface and roller retention.
3) For excellent value, bearings are available with a roller set bore diameter of up to 120 mm dia.

■ Structure



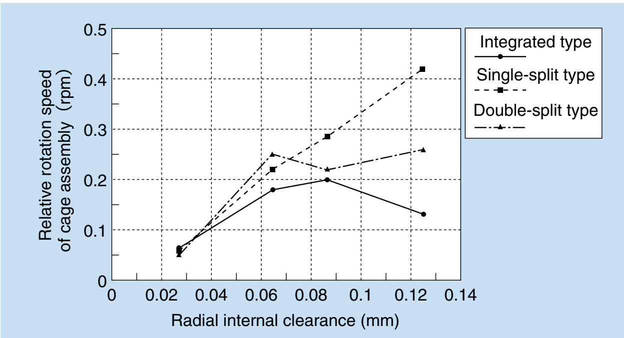
A-A Cross section

■ Welded cage manufacturing process



■ Bearing series and characteristics

KJ······S		● Outside diameter guide cage assembly ● Made from thin band steel. ● Accommodates medium-size shaft diameters ranging from 20 to 40 mm dia. ● Used mainly for car-class transmissions.
KV······S		● Outside diameter guide cage assembly. ● Made from relatively thick steel plate. ● Cage assembly has high-rigidity ring. ● Accommodates large diameters. ● Used mainly for truck-class transmissions. ● **Conventional type does not have rollers installed in the welded pocket.**
SKV······S		● KV······S is temporarily welded, then the weld is separated to create a single-split cage assembly. ● Has anti-fretting feature. (**See following chart**.)
GKV······S		● KV······S is cut apart at almost half its length, and is then bent to form a double-split (half-split) type cage assembly. ● Has anti-fretting feature. (**See following chart**.)



Measured data on the relative rotation speeds according to the difference in cage assembly

9

Full-complement needle roller bearings for sliding seats

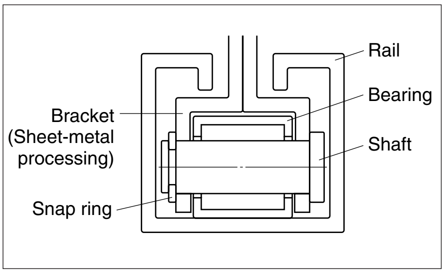
A rolling mechanism is employed to improve the sliding motion of rear seats in minivans.

■ Features

Economical full-complement roller bearings with thick pressed outer ring

1) Thick steel plate is applied directly to the outside surface of the pressed outer ring as the rolling surface for the roller follower.
2) A new pressing process has been introduced for mating components, so less chamfering of the outside surface of the pressed outer ring is required.
3) All press processes are designed for economy.

■ Structure



Rail cross section

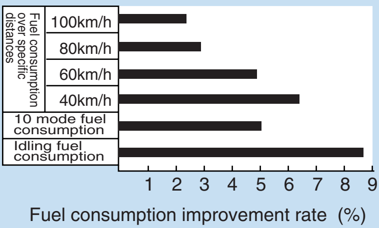
Bearings for Rocker Arms

Automotive manufacturers, both domestic and international, place the highest priority on the technical issue of improving fuel consumption. One aspect of this commitment has been the aggressive pursuit of low-friction engine design. It has been determined that the friction loss of the valve system is high in the low-speed and middle-speed ranges, which are the most frequently used.

Usually, a sliding mechanism known as the "slipper system" is employed, but the needle roller type has been adopted to improve fuel consumption and performance.

■ Features

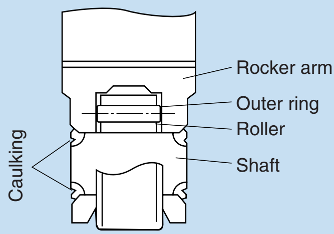
A rocker arm bearing rotates in contact with the engine camshaft. The surface roughness of shaft L is usually R_{max} 2 to 4 μm (Ra 0.5 to 1 μm), and may cause peeling of the surface of the rocker arm bearing. To prevent this, the HL treatment is standard for **NTN** rocker arm bearings.

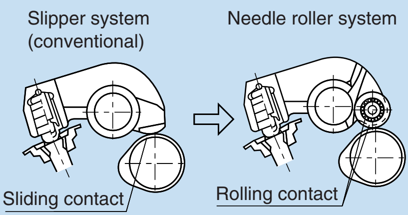


Fuel consumption improvement due to use of needle roller rocker arm

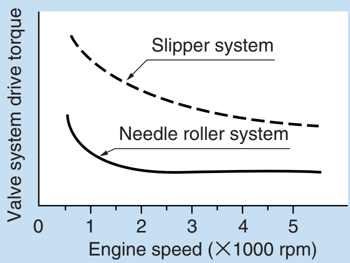
■ Structure

Both ends of the shaft are caulked and fixed with a yoke.





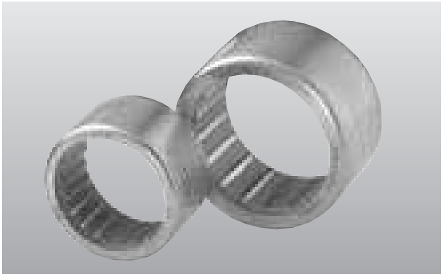
Design comparison



Difference in drive torques

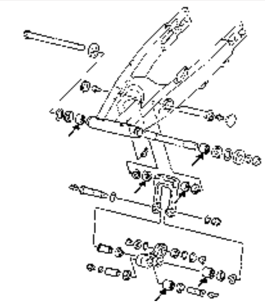
9

Needle roller bearings with solid grease



The bearing is prelubricated with thermosetting grease to ensure maximum advantage.

■ Application



Structure of rear suspension link of two-wheeled vehicle (Arrows indicate bearings.)

■ Features

1) Less lubricant leakage

When thermosetting grease is used, oil is gradually supplied to the rolling contact surface through the generation of heat and centrifugal force during operation of the bearing. As a result, there is less oil leakage.

2) Proper lubrication characteristics

The lubricant is unlikely to leak, even if strong vibrations or a large centrifugal force acts on the bearing. The lubricant will not become emulsified or flow out even if water enters.

Lubrication characteristics are superior to the general grease. However, it may get rust if moisture remains in the shaft, or if the bearings are used under the condition to be forced to get water splash on. Accordingly, we recommend you to take sealing measures such as using the additional seal.

■ Notices for use

Operate the bearing only in an ambient temperature range of –20 to 80˚C. For continuous operation, the ambient temperature should not exceed 60˚C.

Care should be taken since these bearings cannot be used under the condition that the organic solvents (such as acetone, pertoleum-benzine and white kerosene) may splash on.

Cam followers/Roller followers with outer ring grooves

Cam followers with outer ring grooves (above) and various roller followers with outer ring grooves (right)

Bearings are provided with grooves on the outside diameter of the outer ring to match the shape of the mating material. These bearings are used as guide rollers. The groove shape can be processed as an R or V shape. Mounting instructions are identical to those of standard bearings.

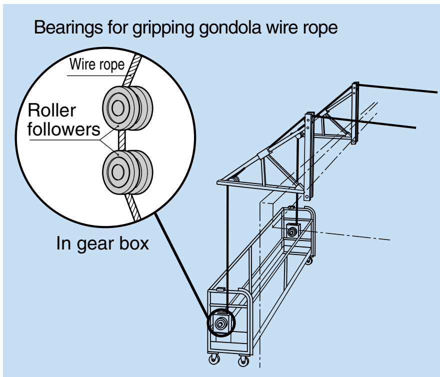
■ Features

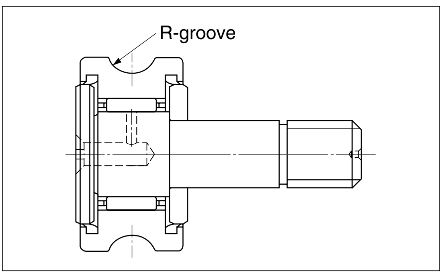
1) The R-groove shape can be mirror-finished according to the requirements of the application. (Generally, turning followed by lapping.)
2) The basic design accommodates the cam follower standard.
3) Easy mounting.
4) Can also be used as an economical guide roller for direct drive machines.

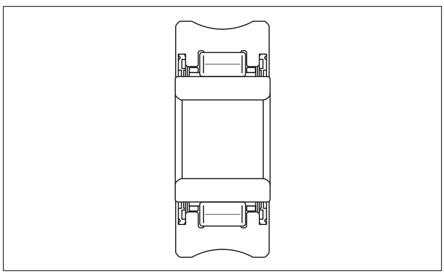
■ Applications

- Guide rollers for steel wires and steel pipes
- Leveling rollers
- Rope-gripping devices for winches of window-washing gondolas

■ Example applications of poly-lubricated bearings







Roller follower with outer ring with center rib

A roller follower with an outer ring with a center rib (**Fig. 1** NUTW Series) comprises cylindrical rollers, an outer ring, an inner ring, side plates, and shield plates. The outer ring follows a rolling motion on the raceway (track). The outer ring is designed to be thick in order to withstand shock loads, as it operates in direct contact with the track.

In addition to the NUTR Series (**Fig. 2**), which was introduced in a succession of models, the width of the outer ring has been widened, the center rib has been equipped with an outer ring, and the roller follower has been designed to carry larger axial loads. The outside surface of the outer ring is spherical or cylindrical. An outer ring with a spherical surface is effective at easing edge loads due to mounting error.

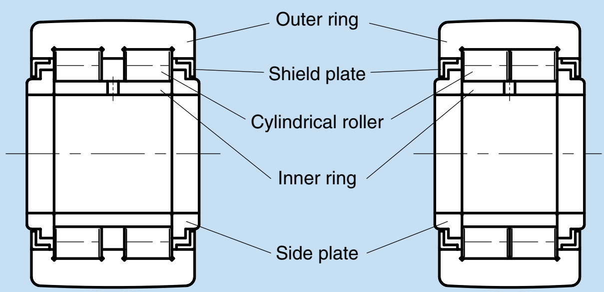


Fig. 1. NUTW Series **Fig. 2. NUTR Series**

■ Features

1) The outer ring is designed to be thick in order to withstand shock loads.
2) The outside surface can have a spherical or cylindrical surface.
3) The outer ring is equipped with a center rib, making it effective against axial loads and the moment loading effect.
4) Increasing the prelubricated grease capacity increases the lubrication effect and contributes to longer service life.

■ Applications

1) Under heavy loads or shock loads
2) As a cam mechanism or guide roller for straight and curved lines
3) Where moment loads act due to installation errors

❶ For bearings with a cylindrical outside surface, add "X" to the bearing series code. In this case, the allowance of the outside diameter "D" of the outer ring is manufactured according to JIS Class O.
Example: NUTW203X

❷ This is the permissible minimum of chamfering dimension r.

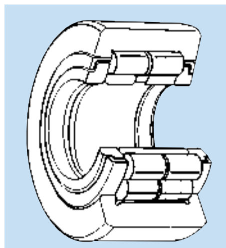
NACV Series



NUTR Series

Cam followers (with eccentric shaft/tapping hole)

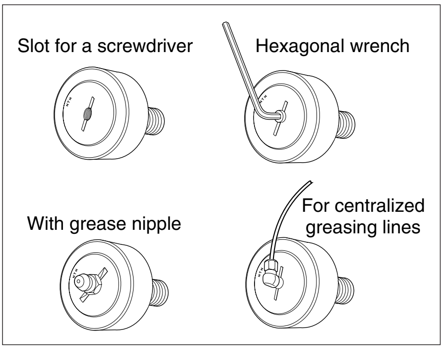
Adoption of an eccentric shaft provides easy adjustment of the mounting position. As a result, highly accurate mounting hole positioning has become unnecessary. Furthermore, the included threaded grease nipple can be installed at the tapping hole on the stud for easy greasing. It can also be used as a mounting thread for centralized pipelines.

■ Features

1) This bearing for outer ring rolling has a thick outer ring and high rigidity.
2) Available in three types: needle roller and cage assembly (KRU Series); needle roller without cage assembly (KRVU Series); and double-row cylindrical rollers (NUKRU Series) according to the type of rolling element.
3) The outside surface of the outer ring is spherical or cylindrical. The KRU Series and KRVU Series are available with seals. The NUKRU Series is sealed with sealing plates.
4) Axial eccentricity is 0.25 to 1.0 mm. This is especially advantageous for level adjustments when many bearings are mounted.
5) The driver groove on the flange side and tapping holes at both ends are provided for the stud. Either a screwdriver or hexagon wrench can be used.
6) Conventional press-greasing work is unnecessary because the threaded grease nipple is provided for greasing.

■ Applications

- Construction machinery, packaging machinery, industrial robots, medical appliances
- Transportation equipment at parking garages and automatic warehouses



Rubber mold cam followers

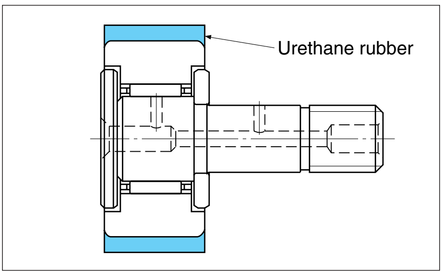
These are cam followers with an outer ring whose outside surface is vulcanized and coated with urethane rubber. This provides an effective means of preventing noise and absorbing vibration.

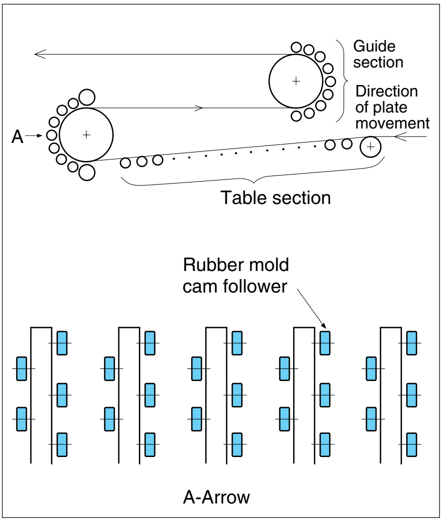
■ Features

1) Prevents noise.
2) Prevents bearing wear and damage.
3) Maintenance-free design
4) Easy installation

■ Applications

- Bridle roller guide





Steel bridle roll structure

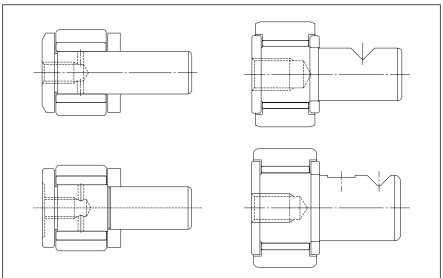
9

Cam followers for indexing

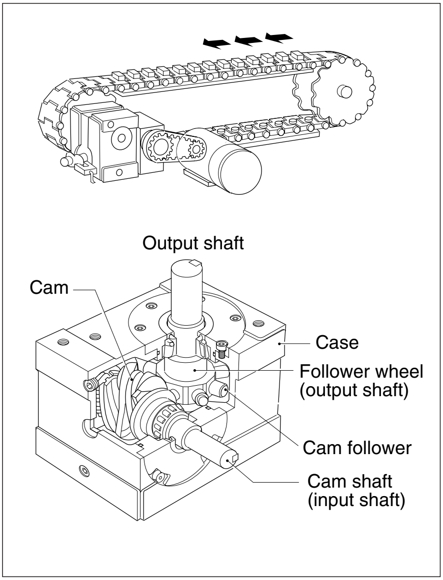
Automatic machinery performs a variety of movements including intermittent, oscillating and continuous rotation with high accuracy and at high speed. Cam followers are used as the roller cam mechanisms of driving devices.

■ Features

1) Provides ample outer ring and stud rigidity in a compact space.
2) Full-complement roller design ensures a long service life and larger load-carrying capacity than a roller and cage assembly.
3) This cam follower offers precision-class dimensions and rotational accuracy.
4) Secured with set screws for easy installation.



Examples of index cam follower shapes



Structure of indexing drive

9

Small-diameter drawn-cup needle roller bearings

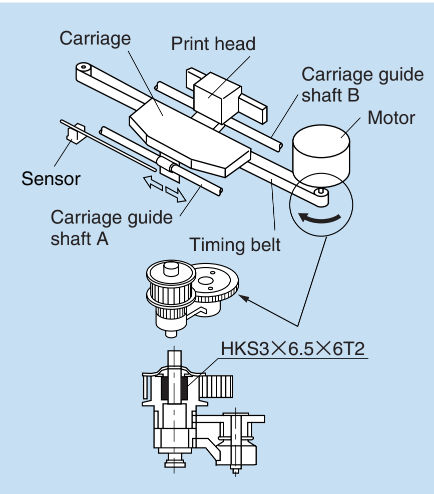
■ **Features**

The small diameter drawn-cup needle roller bearing has a low section height, is assembled with a cage assembly and rollers, and has a set bore diameter dimension (F_w) less than 10 mm. The outer ring surface is hardened by carburizing following precision deep drawing of the thin band steel.

■ **Application**

These bearings have a wide range of application thanks to their low section height and compact design.

Printer (timing pulley a ssembly).



Application: Printer (timing pulley assembly)

9

Bearing units for steel leveler backup roller

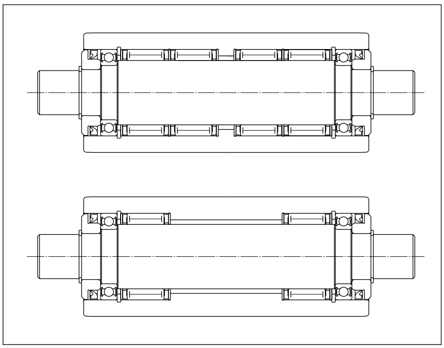
These bearings are used as backup rollers for leveling band steel.
They are available in long and narrow models.

■ Structure and advantages of long bearings

This unit is an assembly comprising a roller, shaft, and bearing. The bearing differs with the intended roll operating conditions, but the design has both a needle roller and cage assembly bearing (when carrying radial loads) and a deep-groove ball bearing (for carrying axial loads).

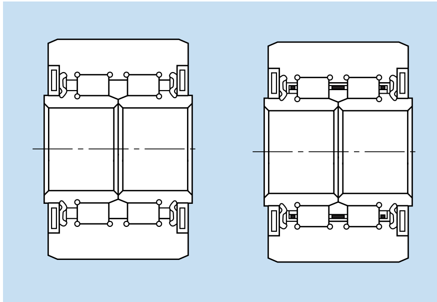
With the sealed type, the deep groove ball bearing seal, rubber seal, and clearances between cover and roller provide a satisfactory seal.

The starting torque and grease prelubrication, as well as the shape, hardness, roughness and rotational accuracy of the roller, meet all the requirements of a backup roller.



NTN can accommodate specifications other than the above for work rollers or leveler units used as middle rollers. For details, refer to "CAT. No. 2250/J, Large Rolling Bearings."

■ Structure and advantages of narrow bearings

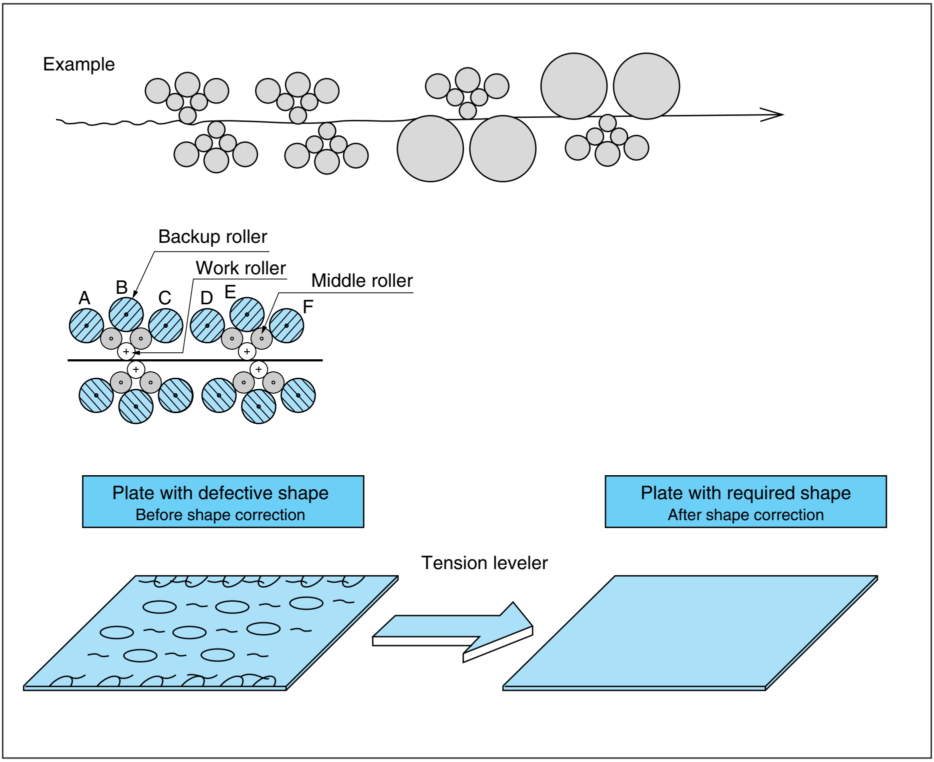


The outer ring has a thick design in order to provide greater rigidity, as the outside surface of the outer ring is used directly as the raceway surface. These bearings carry larger loads because double-row cylindrical rollers are used as the rolling elements.

The internal rubber seal and external steel seal plates of the sealed type form a labyrinth seal that provides a sufficient sealing effect.

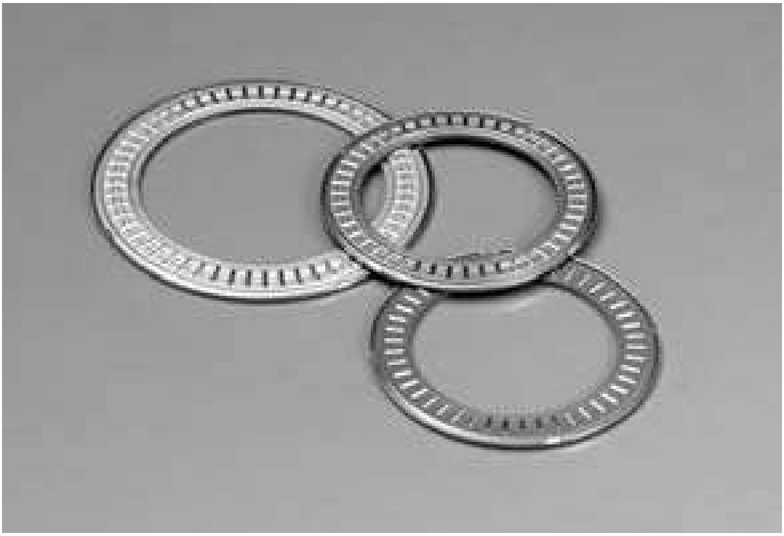
The starting torque and grease prelubrication, as well as the shape, hardness, roughness and rotational accuracy of the roller, meet all the requirements of a backup roller.

■ Application



9

Thrust bearing with integrated non-separable raceway



This non-separable thrust bearing is a remodeled separable bearing comprising of a thrust needle roller bearing and bearing ring made of steel plate, with a new structure designed to hold the cage assembly or other bearing ring with the rib of the bearing ring.

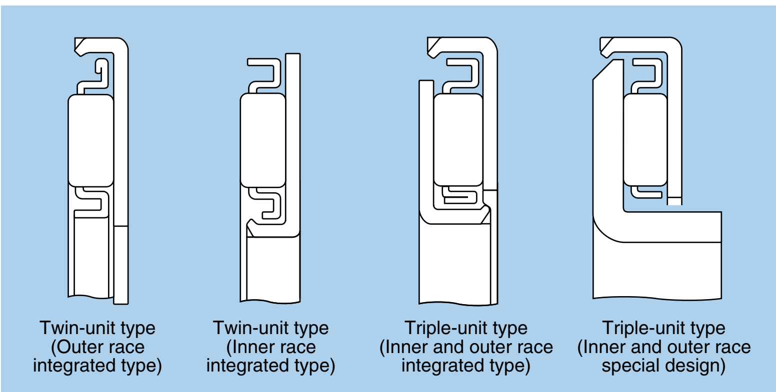
■ Features

The non-separable type of cage assembly and bearing rings ensures easier handling and fewer assembly steps than the standard thrust needle roller bearing.

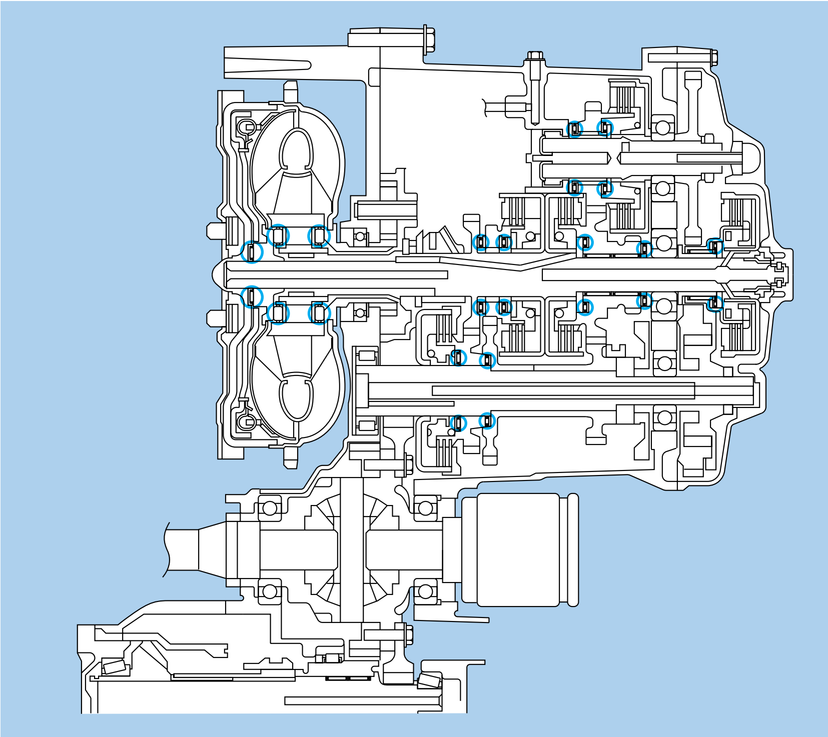
■ Applications

These bearings are used in automotive transmissions and air conditioner compressors.

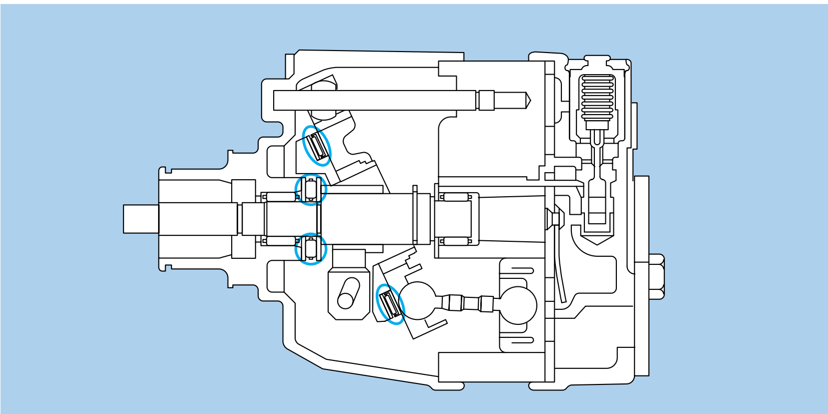
9



Structure



Application example 1: Automatic transmission (Front-mounted engine, front-wheel drive models)



Application example 2: Car air conditioner compressor

Thrust cylindrical roller and cage assemblies (JW) of pressed steel plate

The cage assembly made of pressed steel plate makes for an economical thrust cylindrical roller and cage assembly.

Conventionally, the cage assembly of thrust cylindrical rollers is made of machined aluminum. However, the mass productivity of machined cage assemblies is inferior and their cost is high.

As a result, integrated cage assemblies made of pressed steel plate have been found to provide satisfactory results for the thrust needle rollers of cylindrical roller thrust bearings.

Previously, it was considered difficult to create the pocket shape for W Series cylindrical rollers because of the low ratio of roller length to roller diameter. Now, however, we have succeeded in producing the appropriate shape so that these rollers can be employed in cylindrical roller bearings.

9

■ Features

1) Because steel plate is used for the cage assembly and the rollers are manufactured by press forming, mass productivity is excellent.
2) The use of steel plate for these rollers allows for a variety of heat treatments and surface treatments.
3) Because it is possible to narrow the width of the pillar as well as the distance between the bore diameter/outside diameter and pocket end, the rated capacity of a given size can be increased by increasing the roller length and the number of rollers.

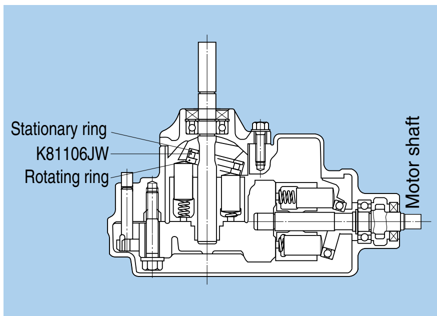
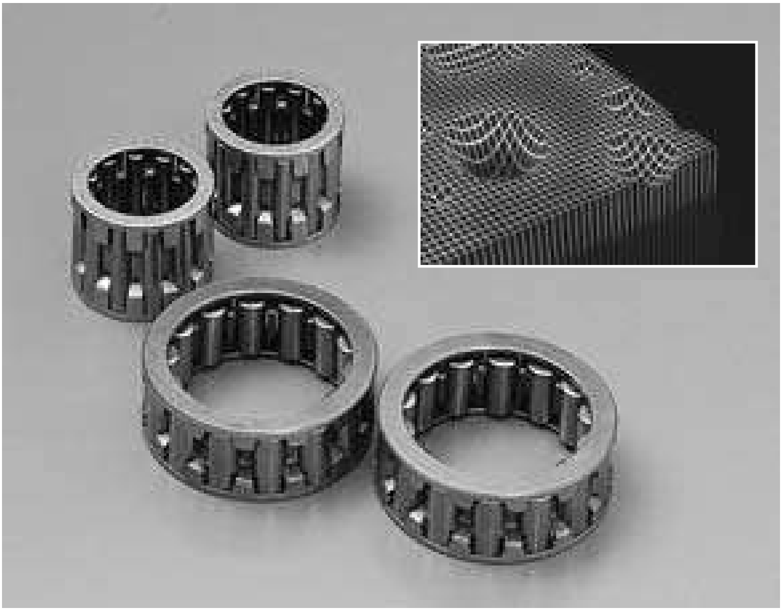
Application: Riding mower



Bearing assembly structure

HL roller bearings



■ Features

If the shaft or housing is used as the raceway surface of a needle roller bearing, in place of an inner ring or outer ring, the bearing will tend to have a short operating life because of a lack of lubricant film caused by the difference in surface roughness between the rollers and mating components (mainly the shaft).

NTN has developed a surface processing method through which a sufficiently thick oil film is maintained under these operating conditions. This method changes the orientation of the surface roughness according to the Micro EHL Theory.

These bearings are called HL (High Lubrication) roller bearings.

A HL surface has no orientation because, as shown in **Fig. 1**, the surface has a large number of minute dimples of more than 10 μm to provide a roughness wave form in the axial and circumference directions. The depth of the dimples is approximately 1 μm.

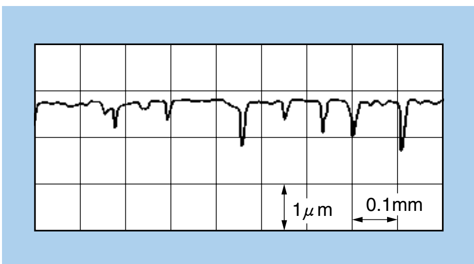


Fig. 1 Roughness of HL surface

9

To confirm the capacity of a HL surface to form an oil film, we compared the oil-film formation capacity of the HL surface with that of a super-finish surface with the 2-cylinder test unit. **Fig. 2** shows the results, which confirm that the HL surface has a greater oil-film formation capacity.

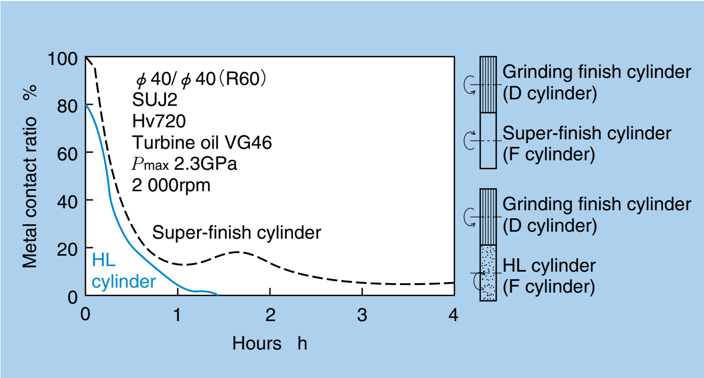

Fig. 2 Metal contact ratio of HL surface

■ Application

The superior oil-film formation capacity enables these roller bearings to achieve optimal performance under severe lubricating conditions, as shown below. Moreover, protection against peeling and an extended service life can be expected. The HL surface can also be applied effectively to bearing rings other than roller bearings.

- Travel speed reducers for construction machinery
- Various types of transmissions
- Engine roller rocker arm
- Hydraulic pumps

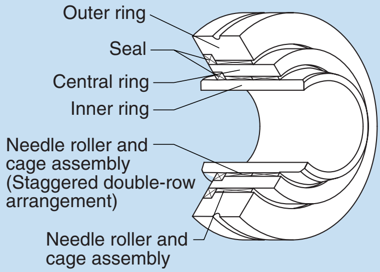
Triple raceway bearings

These needle roller bearings contribute to high-quality printing and easier maintenance.

■ Features

These needle roller bearings boast high-accuracy rotation and dimensions. The adoption of the needle roller bearing design ensures a bearing section with a simple structure and compact design. Assembly and adjustment are simplified and stable, long-term rotation is assured.

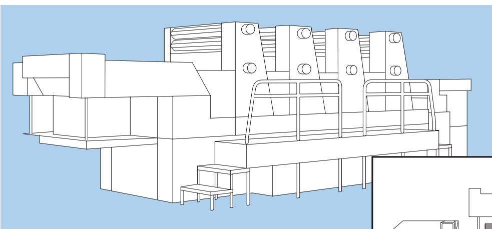
■ Structure



9

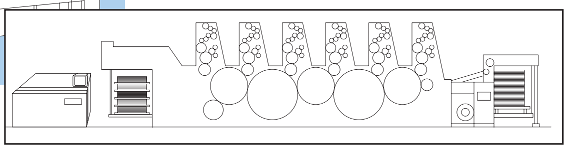
■Applications

- Offset sheet printing machine
  Blanket cylinder (with rubber trunk)
- Maximum speed: 15,000 sheets/hour



▲4-color machine

▼6-color machine



PK Series needle roller and cage assemblies for general production machinery

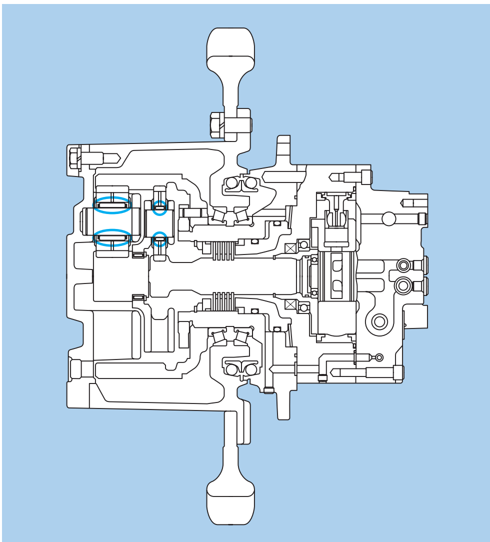
■ Features

The cage assembly features an outside diameter guide structure, which has the same structure and rigidity as the cage assembly for the connecting rod. It is designed for a high loading capacity within the limits of the available space. The cage assembly is of carburized steel, and appropriate heat treatment ensures sufficient strength.

■ Applications

These bearings are widely used in construction machinery, agricultural machinery, hydraulic equipment and the steel industry.

Often, numerous needle roller bearings are used in the planetary gear speed-reduction mechanism for construction machinery. In particular, PK Series roller and cage assemblies are in wide use.



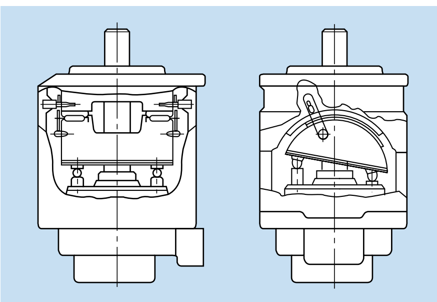
Application: Planetary gear speed reduction mechanism for construction machinery

Cradle bearings

In recent years, the use of an arc-shaped rolling bearing behind the swash plate, instead of the conventional trunnion system and sliding contact system, has been considered for the variable mechanism of the variable capacity plunger pump motor. Application of this system allows the bearing to carry larger loads in a smaller space. It also solves the problem of friction on the sliding surfaces of the sliding system. In addition, the reduction of oscillating resistance improves response.

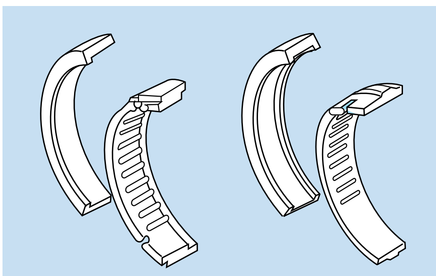
9

■ Application



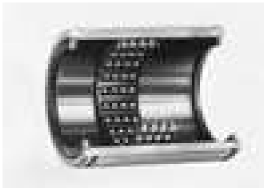
■ Types

The needle roller and cage assembly of these bearings is split (usually into 3 parts) along its circumference. Many bearings have a split outer ring. The single-rib type and double-rib type are shown in the figure.



Bearings for linear motion (KLM, KD, KH)

KLM | **KD** | **KH**



■ Features

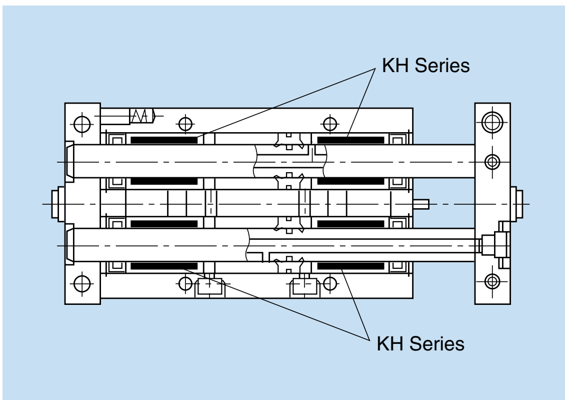
These rolling bearings use steel balls and exhibit excellent friction and motion characteristics compared to sliding bearings. With their easy handling and compact size, they are widely used in applications where stroke movement is required.

With the standard KLM and KH Series, the row of balls rotates to provide unlimited linear motion along the shaft. The outer ring of the KH Series is the drawn-cup type and offers a smaller cross-section. This series is more economical than the KLM Series.

With the KD Series, the equally distributed ball rows in the axial direction reciprocate in limited linear motion along the shaft without rotating.

■ Application

These bearings are used for sliding parts of office appliances or construction machinery. Bearings can be selected according to their specifications (shaft diameter and stroke length).



Application: Work transferring slide unit

10. Nominal number

A nominal number of a bearing expresses the type, dimensions, accuracy and internal structure of the bearing and is composed of the basic number and supplemental code.

Table 10.1 shows the nominal number composition. **Table 10.2** also shows the arrangement order of nominal numbers.

Table 10.1-1 Nominal number composition (Prefix supplemental code, basic number)

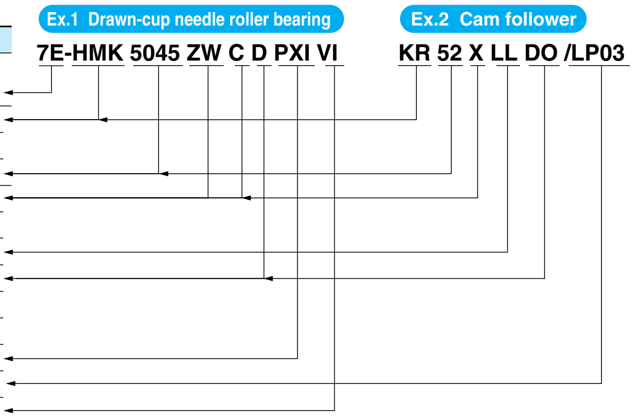
Table 10.2 Arrangement of nominal numbers

Arrangement of nominal numbers	
Suffix supplemental code	Special application code Material, Heat treatment
Basic number	Series code
	Dimension group code inner diameter number
	Dimension code
Suffix supplemental code	Internal change code
	Cage assemblies code
	Seal, shield code
	Raceway shape code
	Combination code
	Internal clearance code
	Accuracy code
	Lubricant code
	Special code



Remarks:
1. Contact **NTN** about the basic number, prefix or suffix supplemental codes other than the list.
2. Soft nitriding treatment is the standard specification for the welded cage assemblies and the prefix supplemental code (8Q-) should be omitted.
3. If the prelubricated grease is standardized per the bearing type and product type, the grease code should be omitted.
4. If the special code (Vn) is used, Vn includes the material, heat treatment and lubrication code, but the internal change code such as prefix supplemental code HL- and ABC, S (welded cage assemblies), seals, locating snap rings, H (with hexagonal hole) combination codes and precision codes are not included in Vn but described.

ROLLING BEARINGS HANDBOOK

CAT. No. 9012-Ⅱ／E

NTN

Rolling Bearings Handbook

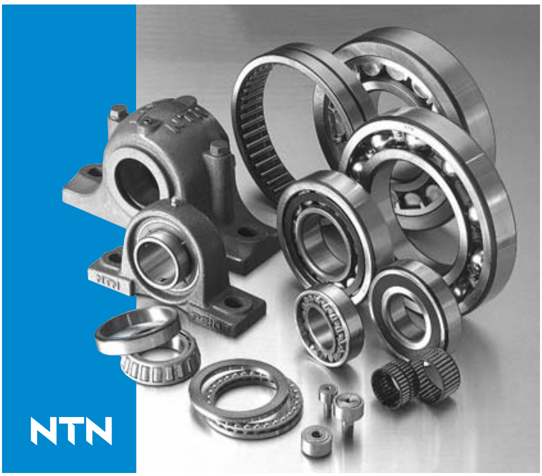
Introduction

When moving an object, friction force often comes into play, and must be surpassed to move the object. Various types of bearings are used to lessen this friction force for moving mechanisms such as machines.

The bearing gets its name from the fact that it bears a turning axle or shaft, but those parts used for sliding surfaces are also called bearings. Bearings include rolling bearings, which use balls, or rollers called "rolling elements."

The history of rolling bearings goes back a long time, but there has been striking technological progress in recent years. Such technological innovations have become an extremely important factor for various types of machines and equipment.

This Rolling Bearing Handbook provides a description of the fundamentals and proper use of rolling bearings in easy-to-understand terms. We hope you find this information helpful.



Contents

1. Rolling Bearings

1.1 Sliding Friction and Rolling Friction

As shown in **Fig. 1.1**, the amount of force it takes to move an object of the same weight varies largely between the cases where the object is laid directly on the ground and pulled, and where the object is laid on rollers and pulled. This is because the coefficient of friction (μ) varies largely for these two cases.

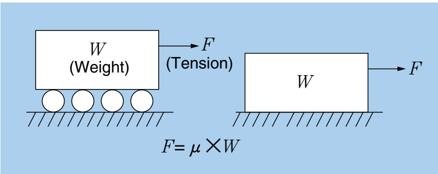


Fig. 1.1 Comparison of Friction Force

The force it takes to bring the object to the verge of moving can be calculated as $F = \mu \times W$, but the value of the coefficient of friction μ of a rolling bearing is a minute value of less than 1/100 that of a sliding bearing. The coefficient of friction of a rolling bearing is generally μ = 0.001 to 0.005.

1.2 Sliding Bearings and Rolling Bearings

There are various forms of each type of bearing, each having its own particular characteristics. If you compare the two, the general characteristics are as follows.

Characteristic	Rolling bearing	Sliding bearing
Construction	Generally has inner and outer rings, in between which there are ball or roller rolling elements which support a rotating load by rolling. 	Rotating load is supported by the surface, and makes direct sliding contact in some cases, or maintains sliding by film thickness using a fluid as a medium. Dimensions	Cross-sectional area is large due to intervention of rolling element.	Cross-sectional area is extremely small.
Friction	Friction torque is extremely small during rotation at start-up.	Friction torque is large at start-up, and may be small during rotation, depending on the conditions.
Internal clearance rigidity	Can be used by making internal clearance negative to provide rigidity as a bearing.	Used with clearance. Therefore, moves only the amount of the clearance.
Lubrication	As a rule, lubricant is required. Using grease, etc., facilitates maintenance; is sensitive to dirt.	Some types can be used without lubrication; generally speaking, are comparatively insensitive to dirt. Oil lubrication conditions require attention.
Temperature	Can be used from high to low temperatures. Cooling effect can be expected, depending on lubricant.	Generally speaking, there are high and low temperature limits.

Dimensions of rolling bearings have been internationally standardized.
The bearings are widely used because they are interchangeable, easy to get, and inexpensive.

2. Classification and Characteristics of Rolling Bearings

2.1 Rolling Bearing Construction

Rolling bearings basically consist of four parts (outer ring, inner ring, rolling elements, cage). The shapes of parts of typical bearings are shown in **Fig. 2.1**.

- **Rolling bearing rings (inner and outer rings) or bearing washer ❶)**

The surface on which the rolling elements roll is referred to as the "raceway surface." The load placed on the bearings is supported by this contact surface. Generally speaking, the inner ring is used fitted on the shaft and the outer ring on the housing.

❶ In the new JIS (Japanese Industrial Standards), rolling bearing rings of thrust bearings are referred to as "rolling bearing washers," the inner ring as "shaft washer," and the outer ring as "housing washer."

- **Rolling elements**

Rolling elements come in two general shapes: balls or rollers. Rollers come in four basic styles: cylindrical, needle, tapers and spherical. Rolling elements function to support the load while rolling on the bearing ring.

- **Cages**

Along with keeping the rolling elements in the correct position at a uniform pitch, cages also function to prevent the rolling elements from falling out. Cages include pressed cages pressed out of metal plating, precut machined cages, and resin formed cages.

Bearing type	Finished part	Part			
		Outer ring	Inner ring	Rolling elements	Cage
Deep groove ball bearing					Cylindrical roller bearing					Tapered roller bearing					Self-aligning roller bearing					Needle roller bearing					
Fig. 2.1 Comparison of Typical Rolling Bearings

2

2.2 Classification of Rolling Bearings

Rolling bearings are generally classified as shown in **Fig. 2.2**. In addition to these, there are bearings of various other shapes.

For more information, see the various **NTN** catalogs. For terminology used for the parts of typical bearings, see **Fig. 2.3**.

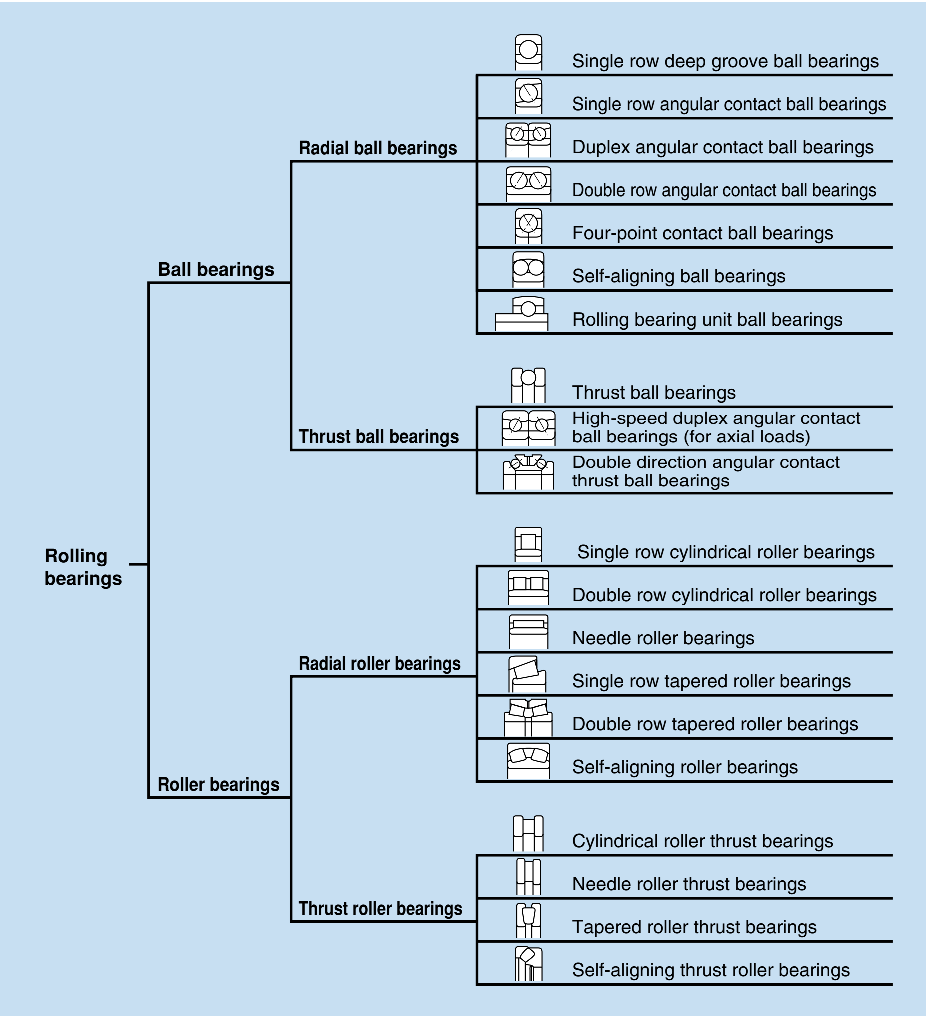

Fig. 2.2 Classification of Roller Bearings

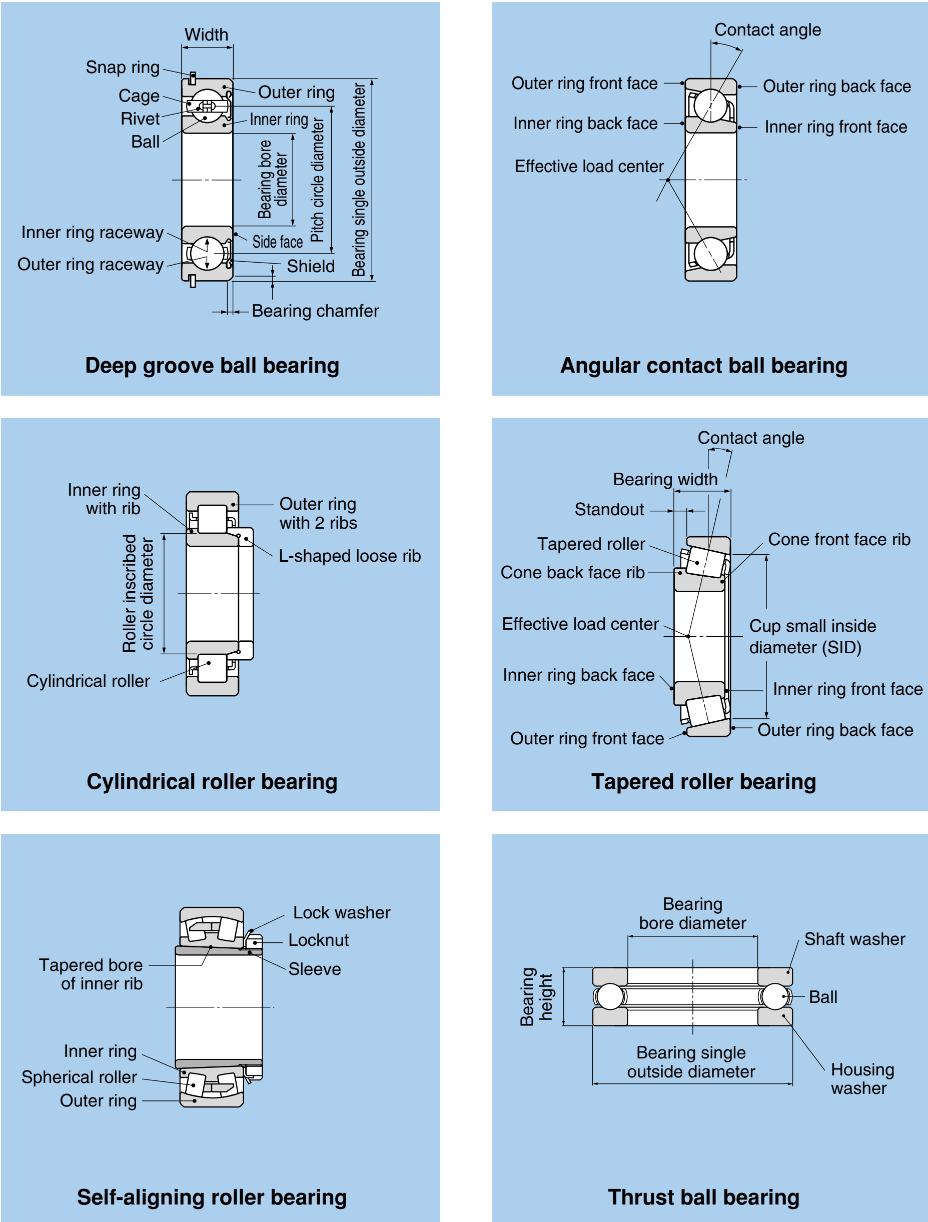

Fig. 2.3 Terminology of Bearing Parts

2.3 Bearing Manufacturing Process

There are many types of bearings, and manufacturing processes with many fine points of difference according to the type of bearing. Generally speaking, bearing manufacturing consists of the processes of forging, turning, heat treatment, grinding, and assembly.

The manufacturing process for deep groove ball bearings is shown below.

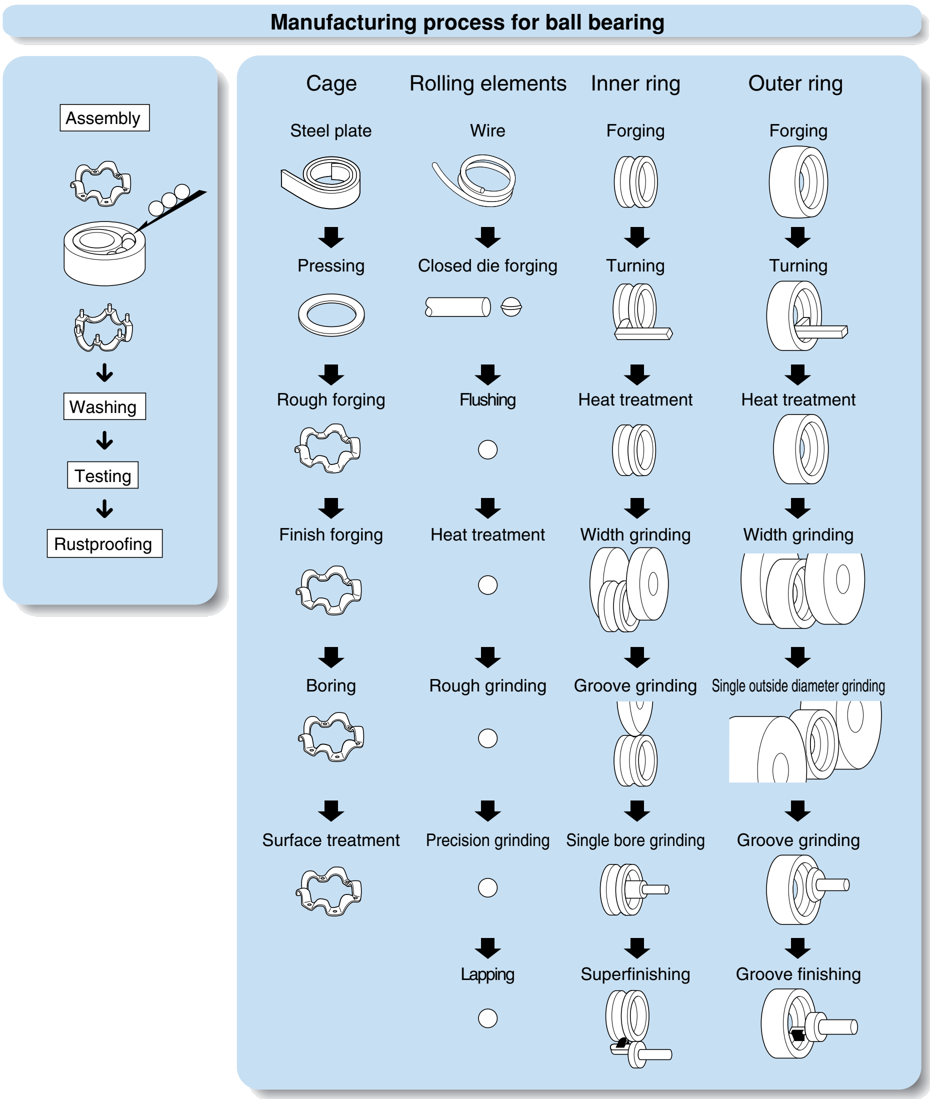

Fig. 2.4 Deep Groove Ball Bearing Manufacturing Process

2.4 Characteristics

● Ball bearings and roller bearings

Table 2.1 Comparison of Ball Bearings and Roller Bearings

	Ball bearings	Roller bearings
Contact with bearing ring	Point contact Contact surface becomes elliptical when a load is received. 	Line contact Contact surface generally becomes rectangular when a load is received. Characteristics	Balls make point contacts, so rolling resistance is slight, thus making it suitable for low torque, high-speed applications. Also has superior sound characteristics.	Because axial contact is made, rotation torque is less than that of balls, and rigidity is high.
Load capacity	Load capacity is small, so loads can be received in both radial and axial directions with radial bearings.	Load capacity is large. With cylindrical roller bearings with ribs, slight axial load can also be received. With tapered roller bearings, a combination of two bearings enables large axial load in both directions to be received.

● Deep Groove Ball Bearings

Widely used in a variety of fields, deep groove ball bearings are the most common type of bearing. Deep groove ball bearings may include seals or shields as shown in **Table 2. 2**.

Deep groove ball bearings also include bearings with snap rings for positioning when mounting the outer ring; expansion adjustment bearings which absorb dimension variation of the bearing fitting surface caused by temperature of the housing; and other various types of bearings such as TAB bearings which can withstand dirt in the lubrication oil.

Table 2.2 Construction and Characteristics of Sealed Ball Bearings

Type and symbol		Shielded type	Sealed type		
		Non-contact type ZZ	Non-contact type LLB	Contact type LLU	Low torque type LLH
Construction							● A metal shield is fastened to the outer ring, forming a labyrinth clearance with the V-groove of the inner ring seal surface.	● A seal plate of synthetic rubber anchored to a steel plate is fastened to the outer ring, and the edge of the seal forms a labyrinth clearance along the V-groove of the inner ring seal surface.	● A seal plate of synthetic rubber anchored to a steel plate is fastened to the outer ring, and the edge of the seal makes contact with the side of the V-groove of the inner ring seal surface.	● Basic construction is the same as the LU type, except the lip of the seal edge is specially designed with a slit to prevent absorption, forming a low-torque seal.
Performance comparison	Friction torque	Small	Small	Somewhat large	Medium
	Dustproof	Good	Better than ZZ type	Best	Better than LLB type
	Waterproof	Poor	Poor	Extremely good	Good
	High speed	Same as open type	Same as open type	Contact seal is limited	Better than LLU type
	Allowable temperature range ❶	-25˚C~120˚C	-25˚C~120˚C	-25˚C~120˚C	-25˚C~120˚C

❶ Allowable temperature range is indicated for standard product.

Angular Contact Ball Bearin
Single and duplex arrangements 79
High speed single and duplex arrange
Ultra-high speed angular contact ball
Ceramic ball angular contact ball bea
Four-point contact ball bearings QJ2
Double row angular contact ball beari

● Angular Contact Ball Bearings

The straight line that connects the inner ring, ball and outer ring runs at an angle (contact angle) to the radial direction. The angle is basically designed for three types of contact angle.

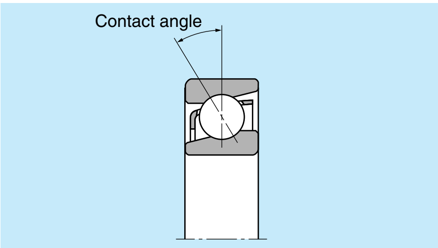
Angular contact ball bearings can bear an axial load. Since they however posses a contact angle, they cannot be used by themselves, but must rather be used in pairs or in combination. There is also a series that reconsiders internal design for high speed.

For more information, see the catalog. ☞

There are double row angular contact ball bearings that contain the inner and outer rings all in one, instead of duplex bearings, and have 30˚C contact angle.

Another bearing is the four-point contact ball bearing which can receive an axial load in both directions. Problems of temperature rise and friction however may occur depending upon load conditions.

Table 2.3 Contact Angle and Symbol



Contact Angle and Contact Angle Symbol

Contact angle	15˚	30˚	40˚
Contact angle symbol	C	A ❶	B

❶ Contact angle symbol A is omitted in nomenclature.

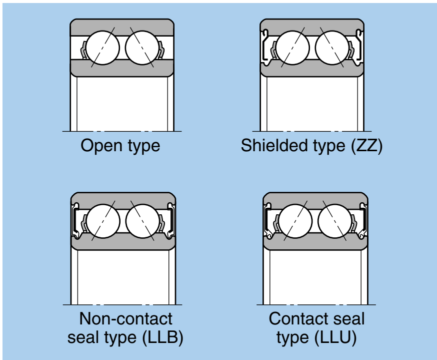


Fig. 2.5 Double Row Angular Contact Bearings

Table 2.4 Combinations Types and Characteristics of Duplex Angular Contact Bearings

Combination		Characteristics
Back-to-back duplex (DB)		● Able to receive radial load and axial load in both directions. ● Distance ℓ between load centers of bearings is large. Load capacity of moment load is consequently also large. ● Allowable inclination angle is small.
Face-to-face duplex bearing (DF)		● Able to receive radial load and axial load in both directions. ● Distance ℓ between load centers of bearings is small. Load capacity of moment load is consequently also small. ● Allowable inclination angle is larger than that of back-to-back duplex.
Tandem duplex bearing (DT)		● Able to receive radial load and axial load in one direction. ● Receives axial load in tandem. Is consequently able to receive a large axial load.

Remarks 1. Bearings are made in sets in order to adjust preload and internal clearance of the bearing, so a combination of bearings having the same product number must be used.

● Cylindrical Roller Bearings

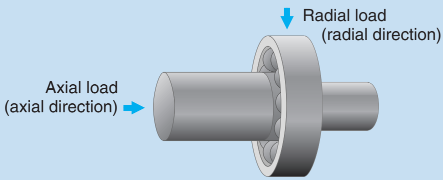
Because cylindrical roller bearings use rollers for rolling elements, load capacity is large, and the rollers are guided by the ribs of the inner and outer rings. The inner and outer rings can be separated to facilitate assembly, and tight fitting is possible for either. Types where either the inner or outer ring does not have a rib move freely in the direction of the shaft and therefore, are ideal for use as so-called "floating-side bearings" that absorb elongation of the shaft. Types with a rib, on the other hand, can receive an axial load, albeit slight, between the roller end face and rib. In order to further enhance axial load capacity, there is the HT type that takes roller end face shape and rib into consideration, and the E-type cylindrical roller bearing with a special internal design for raising radial load capacity. The E-type is standard for small diameter size. Basic shape is given in **Table 2.5**.

Besides these, there are full complement SL bearings without cages and bearings with multiple rows of rollers suitable for even larger loads.

Table 2.5 Types and Characteristics of Cylindrical Roller Bearings

Bearing type symbol	Example	Characteristics
NU type N type	 NU type N type	● The NU type has double ribs on the outer ring, and the outer ring / roller / cage assembly and inner ring can be separated. The N type has double ribs on the inner ring, and the inner ring / roller / cage assembly and outer ring can be separated. ● Cannot receive any axial load whatsoever. ● Most suitable types for floating side bearing; widely used.
NJ type NF type	 NJ type NF type	● The NJ type has double ribs on the outer ring, and a single rib on the inner ring; the NF type has a single rib on the outer ring, and double ribs on the inner ring. ● Able to receive axial load in one direction. ● If fixed and floating sides are not differentiated, they may be used by placing two close together.
NUP type NH type (NJ + HJ)	 NUP type NH type	● The NUP type has a loose rib mounted on the side of inner ring with no rib, and the NH type has an L-type loose rib mounted on the NJ type. The loose ribs can be separated, so the inner ring must be fixed in the axial direction. ● Able to receive an axial load in both directions. ● Sometimes used as a fixed side bearing.

Load Direction and Name



2

● Tapered Roller Bearings

The tapered vertex of the rollers and raceway surface of the outer and inner rings is designed to intersect a point on the centerline of the bearing. The rollers therefore are guided along the raceway surface by being pushed against the inner ring rib by synthetic power received from the outer and inner ring raceway surfaces.

Because component force is produced in the axial direction when a radial load is received, the bearings must be used in pairs. The outer and inner rings with rollers come apart, thus facilitating mounting with clearance and preload. It is however difficult to control the clearance. Tapered roller bearings are capable of receiving both large radial and axial loads.

NTN bearings with 4T-, ET-, T- and U conform to ISO and JIS sub-unit dimensions standards (contact angle, outer ring groove small diameter, outer ring width), and have international compatibility.

NTN offers bearings made of carburizing steel to extend life, such as ETA- and ET- bearings. We also have double row tapered roller bearings that combine two bearings, and heavy-duty four row tapered roller bearings.

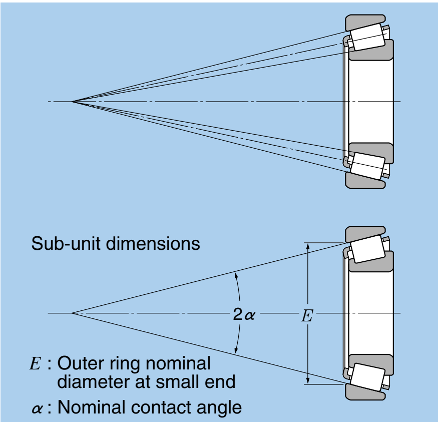


Fig. 2.6 Tapered Roller Bearing

● Self-Aligning Roller Bearings

Having an outer ring with a spherical raceway surface and an inner ring with a double row of barrel-shaped rolling elements, self-aligning roller bearings enable alignment of shaft inclination.

Types of self-aligning roller bearings differ according to internal design.

Some have a tapered inner ring bore to facilitate mounting on the shaft by adapter or withdrawal sleeve. The bearings are capable of receiving large loads and are therefore often used in industrial machinery. Single row rollers however bear no load when axial load becomes great, and are subject to various other problems.

Table 2.6 Types of Self-Aligning Roller Bearings

Type	Standard type (B type)	C type	213 type	E type
Construction				Bearing series	Other than C type	Bore 50 mm or series (222, 223, 213) and 24024 - 24038	Single bore 55 mm or more (213)	22211 - 22218
Roller	Asymmetrical rollers	Symmetrical rollers	Asymmetrical rollers	Symmetrical rollers
Roller guide system	By center rib united with inner ring	By guide ring positioned between rows of rollers	By guide ring between rows of rollers positioned on the outer ring raceway	By high-precision cage (no center rib or guide ring)
Cage type	Pressed cage Machined cage	Pressed cage	Machined cage	Resin formed cage

● Thrust Bearings

There are various types of thrust bearings that differ according to application and shape of rolling elements. Allowable speed is generally low, and lubrication requires attention.

There are various types of thrust bearings for special applications besides those listed below. For more information, see the **NTN** catalogs.

Table 2.7 Types and Characteristics of Thrust Bearings

Type	Characteristics
● Single-direction thrust ball bearing 	Has balls retained by a cage between the shaft washer (equivalent of inner ring) and housing washer (equivalent of outer ring), and is capable of receiving an axial load in one direction only.
● Needle roller thrust bearing  AXK type  AS type bearing washer  GS/WS type bearing washer	Some bearing washers use precut bearing washers, and some use bearing washers of pressed steel plate. Pressed bearing washers are used for bearings with the smallest cross-section height and large load capacity.
● Cylindrical roller thrust bearing 	The most common type uses a single row of cylindrical rollers, but some use two or three rows for larger load capacity.
● Self-aligning thrust roller bearing 	The raceway surface of the housing washer (outer ring) has a spherical surface that lines up with the bearing axis, and uses barrel shaped rolling elements to facilitate alignment. Self-aligning thrust roller bearings are capable of bearing large axial loads. The bearings have many sliding surfaces such as roller end faces and cages, and therefore requires lubricating oil even at low speeds.

● Needle Roller Bearings

The needle-shaped rollers used as rolling elements have a diameter of 6 mm or less and length three to ten times the diameter. Because needle rollers are used as rolling elements, cross-section height is slight and load capacity is large for the dimensions. Because the bearing has many rolling elements, rigidity is high, therefore it suitable for rocking motion.

There are many types of needle roller bearings, but here we shall introduce the most typical types only. For details, see the **NTN** catalog.

Table 2.8 Main Types and Characteristics of Needle Roller Bearings

Type	Characteristics
● Needle roller bearing with cage 	Most basic type of bearing, where the needle rollers are retained by the cage. Because the shaft and housing are directly used as the raceway surface, hardness and finish surface roughness require attention. There are various cage materials and shapes available.
● Machined ring needle roller bearing 	The basic shape is a precut outer ring attached to the previously described needle roller bearing with cage, and some are further equipped with an inner ring. In the case of a double rib type outer ring, there are many types where the cage is set in the bore diameter side and the needle rollers are inserted from the bore diameter. Some also come with seals.
● Drawn cup needle roller bearing 	With drawn cup needle roller bearings, the outer ring has a deep drawn steel plate and is press fit into the housing. Precision bore diameter shape of the housing affects the bearing performance as is. Housing precision therefore requires attention. The bearing on the other hand is retained by press fitting only, so it doesn't require snap rings, etc., thus enabling more economic design. This type includes sealed bearings and closed end bearings where one end is closed.
● Yoke type track rollers **● Stud type track rollers** 	Bearing is used for rolling where the outer ring single outside diameter is made to come in direct contact with the counterpart material. There is no need to cover the outer ring with a tire, etc., thus enabling compact design. Wear life however varies according to operating conditions and hardness of counterpart material.

● **Bearing Unit**

The unit that incorporates ball bearings inside housings of various shapes and sizes. The housing is mounted by bolting to the machine, and the shaft is simply attached to the inner ring by lockscrew. This means that rotating equipment can be supported without any sort of special design in the periphery of the bearing. Standardized housing shapes include pillow and flange types. The single outside diameter of the bearing is spherical, as is the bore diameter of the housing, to facilitate alignment.

Lubrication is sealed inside the bearing by grease; the double seal prevents dust from getting inside.

For more information concerning shapes, see the **NTN** catalog.

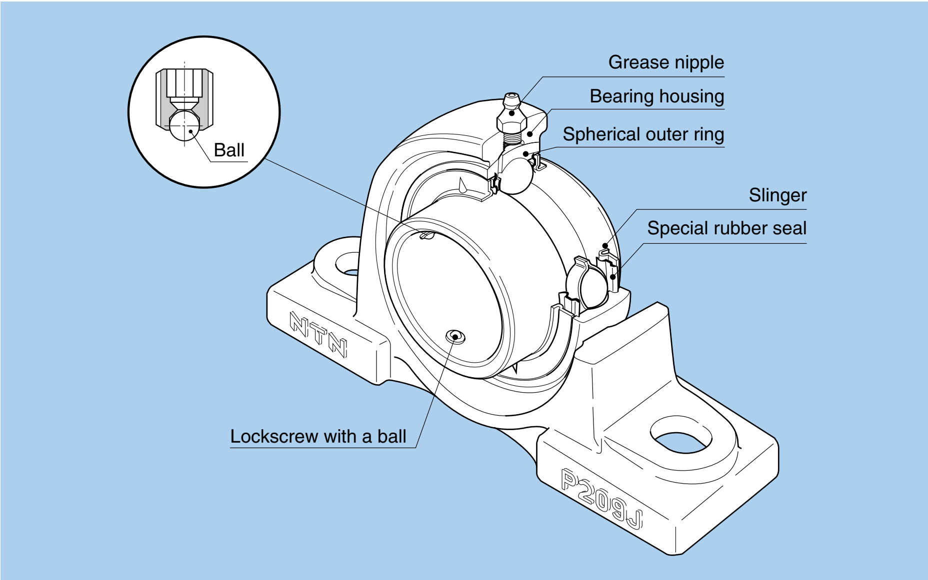

Fig. 2.7 Oiling Type Bearing Unit

3. Bearing Selection

3.1 Selection Procedure

Rolling bearings include many types and sizes. Selecting the best bearing is important for getting the machine or equipment to function in the way it's supposed to. There are various selection procedures, but the most common are shown in the following figure.

Procedure	Check items
Confirm operating conditions and operating environment	● Function and construction of components to house bearings ● Bearing mounting location ● Bearing load (direction and magnitude) ● Rotational speed ● Vibration and shock load ● Bearing temperature (ambient and friction-generated) ● Operating environment (potential for corrosion, degree of contamination, extent of lubrication)
↓ Select bearing type and configuration	● Allowable space of bearing ● Bearing load (magnitude, direction, vibration, presence of shock load) ● Rotational speed ● Bearing precision ● Rigidity ● Allowable misalignment of inner/outer rings ● Friction torque ● Bearing arrangement (floating side, fixed side) ● Installation and disassemble requirements ● Bearing availability and cost
↓ Select bearing dimensions	● Design life of components to house bearings ● Dynamic/static equivalent load conditions and life of bearing ● Safety factor ● Allowable speed ● Allowable axial load ● Allowable space
↓ Select bearing precision	● Shaft runout precision ● Rotational speed ● Torque fluctuation ● Noise level
↓ Select bearing's internal clearance	● Material and shape of shaft and housing ● Fit ● Temperature differential between inner/outer rings ● Allowable misalignment of inner/outer rings ● Load (magnitude, nature) ● Amount of preload ● Rotational speed
↓ Select cage type and material	● Rotational speed ● Noise level ● Vibration and shock load ● Load fluctuation ● Moment load ● Misalignment of inner/outer rings ● Lubrication type and method
↓ Select lubricant, lubrication method, sealing method	● Operating temperature ● Rotational speed ● Lubrication type and method ● Sealing method ● Maintenance and inspection
↓ Select any special bearing specifications	● Operating environment (high/low temperature, vacuum, pharmaceutical, etc.) ● Requirement for high reliability
↓ Confirm handling procedures	● Installation-related dimensions ● Assembly and disassembly procedures

3.2 Types and Performance Comparison

A comparison of the performance of the main rolling bearings is given in the following table.

Table 3.1 Types and Performance of Rolling Bearings

Bearings types / Characteristics	Deep groove ball bearings 	Angular contact ball bearings 	Cylindrical roller bearings 	Needle roller bearings 	Tapered roller bearings 	Self-aligning roller bearings 	Thrust ball bearings Load carrying capacity  Radial load / Axial load			 ❸				
High speed rotation ❶	☆☆☆☆	☆☆☆☆	☆☆☆☆	☆☆☆	☆☆☆	☆☆	☆
Low noise/vibration ❶	☆☆☆☆	☆☆☆	☆	☆			☆
Low friction torque ❶	☆☆☆☆	☆☆☆	☆				
High rigidity ❶			☆☆	☆☆	☆☆	☆☆☆	
Allowable misalignment for inner/outer rings ❶	☆					☆☆☆	★
Non-separable or separable ❷			○	○	○		○

❶ ☆The number of stars indicates the degree to which that bearing type displays that particular characteristic.
★Not applicable to that bearing type.
❷ ○Indicates both inner ring and outer ring are detachable.
❸ Some cylindrical roller bearings with rib can bear an axial load.

3

3.3 Bearing Arrangement

Shafts are generally supported by two bearings in the radial and axial directions. The side that fixes relative movement of the shaft and housing in the axial direction is called the "fixed side bearing," and the side that allows movement is called the "floating side bearing." The floating side bearing is needed to absorb mounting error and avoid stress caused by expansion and contraction of the shaft due to temperature change. In the case of bearings with detachable inner and outer rings such as cylindrical and needle roller bearings, this is accomplished by the raceway surface. Bearings with non-detachable inner and outer rings, such as deep groove ball bearings and self-aligning roller bearings, are designed so that the fitting surface moves in the axial direction.

If bearing clearance is short, the bearings can be used without differentiating between the fixed and floating sides. In this case, the method of having the bearings face each other, such as with angular contact ball bearings and tapered roller bearings, is frequently used.

Table 3.2 (1) Sample Bearing Arrangement (fixed and floating sides differentiated)

Arrangement		Abstract	Application example (reference)
Fixed side	Floating side		
		1. Typical arrangement for small machinery. 2. Capable of bearing a certain degree of axial load, as well as radial loads.	Small pumps Automobile transmissions
		1. Capable of bearing heavy loads. 2. You can enhance rigidity of shaft system by using back-to-back duplex bearing and applying preload. 3. Required improvement of shaft/housing precision and less mounting error.	General industrial machinery Reduction gears
		1. Frequently used in general industrial machinery for heavy loads and shock loads. 2. Able to tolerate a certain degree of mounting error and shaft flexure. 3. Capable of bearing radial loads and a certain degree of axial load in both directions.	General industrial machinery Reduction gears

Table 3.2 (2) Sample Bearing Arrangement (fixed and floating sides not differentiated)

Arrangement	Abstract	Application example (reference)
	1. Typical usage method for small machinery. 2. Preload sometimes provided by spring or adjusted shim on outer ring side.	Small electrical machinery Small Reduction gears
 Back mounting  Front mounting	1. Able to withstand heavy loads and shock loads, and has a wide range of use. 2. Rigidity can be enhanced by applying preload, but be careful not to apply too much preload. 3. Back mounting is suitable when moment load is produced, and front mounting when there is mounting error. 4. Front mounting facilitates mounting when the inner ring is tight-fitted.	Reduction gears Front and rear axles of automobiles

4. Main Dimensions and Bearing Numbers

4.1 Main Dimensions

As shown in **Figs. 4.1 - 4.3**, main dimensions of rolling bearings include bearing bore diameter, single outside diameter, width/height, and chamfer. These dimensions must be known when mounting on the shaft and housing.

The main dimensions have been standardized by the International Standards Organization (ISO), and the Japanese International Standard (JIS) is used in Japan.

The standard range of dimensions for single bore metric rolling bearings has been established as 0.6 - 2500 mm. For single bore, a code is used to express diameter series and width series, which indicate the size of the bearing cross-section.

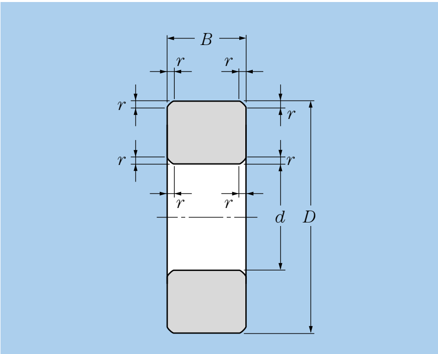

Fig. 4.1 Radial Bearing (tapered roller bearings not included)

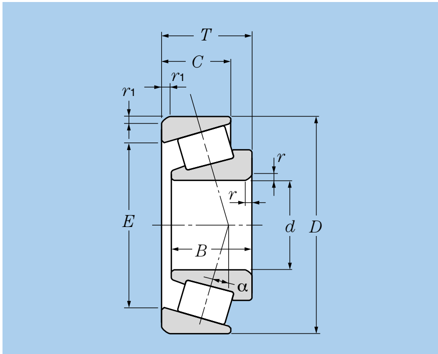

Fig. 4.2 Tapered Roller Bearing

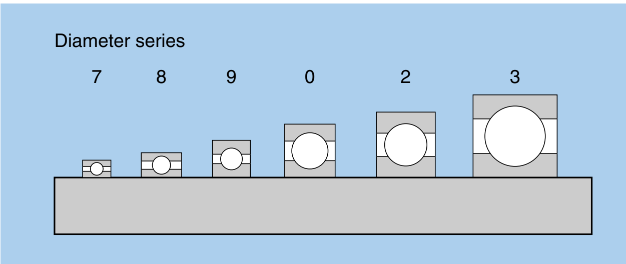

Fig. 4.3 Diameter Series of Radial Bearings

Table 4.1 Dimension Series Code

		Dimension series	
		Diameter series (outer dimension)	Width series (width dimension)
Radial bearing (tapered roller bearings not included)	Code	7. 8. 9. 0. 1. 2. 3. 4	8. 0. 1. 2. 3. 4. 5. 6

Tapered roller bearing	Code	9. 0. 1. 2. 3	0. 1. 2. 3
	Dimension	Small ←→ Large	Small ←→ Large

4

4.2 Bearing Numbers

Bearing numbers indicate the type, dimensions, precision and internal construction of the bearing. Bearing numbers are comprised of a basic number and supplementary code. The arrangement sequence of bearing numbers is as shown in **Table 4.2**.

Special code contents are given in **Table 4.3**.

Table 4.2 Configuration and Arrangement Sequence of Bearing Numbers

Prefix supplementary code Special application / material / heat treatment code		Basic number

5. Bearing Precision

5.1 Dimension and Turning Precision

Dimension and turning precision are regulated by ISO and JIS standards.

Dimension precision

- Single bore, single outside diameter, width, assembled bearing width tolerance
- Chamfer dimensions, tapered hole tolerance

Shape precision

- Bore diameter variation, mean bore diameter deviation, outside diameter variation, mean outside diameter variation
- Bearing ring width or height variation (in case of thrust bearing) tolerance

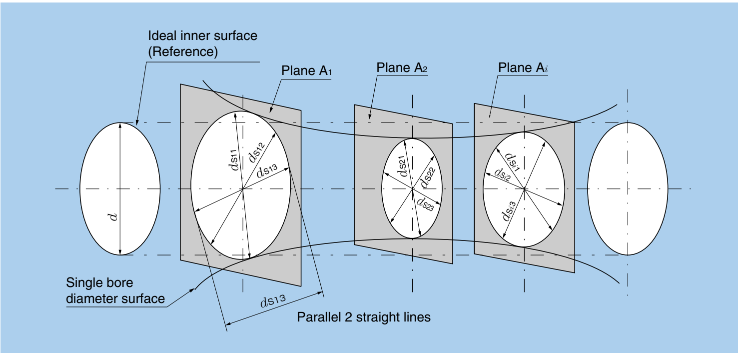
Turning precision

- Inner/outer ring radial and axial runout tolerance
- Inner ring face runout with bore tolerance
- Outer ring variation of outside surface generatrix inclination with face

5

Explanation of JIS Terminology

Because there are ambiguous expressions concerning dimension precision among those given in **Table 5.1**, an explanation of JIS terminology is provided below. (The terminology for outside surface is the same and has therefore been omitted.)



Shape Model Diagram

Nominal bore diameter d:
Reference dimension that expresses the size of a single bore diameter. Reference value for the dimension tolerance of the actual bore diameter surface.

Single bore diameter d_s:
Distance between two parallel straight lines that touch the intersecting line of the actual bearing bore diameter surface and radial plane.

Dimension tolerance of single bore diameter Δd_s:
Difference between d_s and d (difference between a single bore diameter and nominal bore diameter).

Single plane mean bore diameter d_{mp}:
In the arithmetic mean and model of the maximum and minimum values of a single bore diameter inside a single radial plane, concerning any radial plane A$_i$, if d_{si1} is the maximum single bore diameter and d_{si3} in the minimum, you get the value $(d_{si1} + d_{si3})$ /2. Thus there is one value per plane.

With ISO492, ISO 199 (JIS B 1514), precision class is decided; with JIS 0 class (generally called "ordinary class"), precision increases in the order of class 6 → class 5 → class 4 → class 2. **Table 5.1** is a sample precision table for radial bearings.

There are various other standards besides ISO (JIS).

The most frequently requested ones are provided as a reference in the back of this handbook.

Mean bore diameter d_m:

In the model diagram, the arithmetic mean of the maximum and minimum values of a single bore diameters obtained from the entire cylinder surface, concerning the entire surface of planes $A_1A_2 \cdots A_i$, if d_{s11} is the maximum measurement value of the single bore diameter and the minimum value is d_{s23}, then $(d_{s11} + d_{s23})/2$ is the mean bore diameter, and has one value for one cylinder surface.

Dimension tolerance of mean bore diameter Δd_m:

Difference between the mean bore diameter and the nominal bore diameter.

Dimension tolerance of single plane mean bore diameter Δd_{mp}:

Difference between the nominal bore diameter and the arithmetic mean of the maximum and minimum values of a single bore diameter of a single radial plane. Value as prescribed by ISO 492, ISO 199 (JIS B 1514).

Bore diameter variation in a single radial plane V_{dp}:

In the model diagram, difference between the maximum and minimum values of a single bore diameter of a single radial plane. In radial plane A_1, if d_{s11} is the maximum single bore diameter and d_{s13} is the minimum, we can obtain one value for the difference V_{dp} concerning the single plane. This characteristic could be thought of as an index for expressing roundness. Value as prescribed by ISO (JIS).

Mean bore diameter variation V_{dmp}:

Difference between the maximum and minimum values of a single plane mean bore diameter obtained for all planes. A unique value is obtained for each individual product. Expresses a type of cylindricity (differs from geometric cylindricity). Value as prescribed by ISO (JIS).

Nominal inner ring width B:

Theoretical distance between both sides of the bearing ring. In other words, the reference dimension for expressing the width of the bearing ring (distance between both sides).

Single inner ring width B_s:

Distance between the actual sides of the inner ring and both points of intersection of straight lines perpendicular to the plane that touches the reference side of the inner ring. Expresses the actual width dimension of the inner ring.

Dimension tolerance of single inner ring width ΔB_s:

Difference between the single inner ring width and the nominal inner ring width, and the difference between the actual inner ring width dimension and inner ring width. Value as prescribed by ISO (JIS).

Inner ring width variation V_{Bs}:

Difference between the maximum and minimum value of a single inner ring width. Value as prescribed by ISO (JIS).

❻ Applies when snap ring is not mounted. ❼ Applies to deep groove bearings and ball bearings such as angular contact ball bearings.
❽ 2.5 mm is included in the dimensional division.

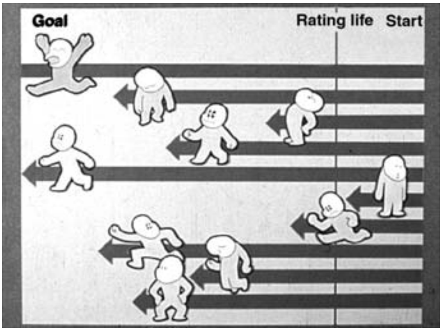
5.2 Bearing Precision Measurement Methods

The figure shows difficult-to-understand turning precision measurement methods only.

Table 5.2 Bearing Precision Measurement Methods

Precision characteristics	Measurement method	
Inner ring radial runout (K_{ia})	 	For inner ring radial runout, record the difference between the maximum and minimum reading of the measuring device when the inner ring is turned one revolution.
Outer ring radial runout (K_{ea})	 	For outer ring radial runout, record the difference between the maximum and minimum reading of the measuring device when the outer ring is turned one revolution.
Inner ring axial runout (S_{ia})	 	For inner ring axial runout, record the difference between the maximum and minimum reading of the measuring device when the inner ring is turned one revolution.
Outer ring axial runout (S_{ea})	 	For outer ring axial runout, record the difference between the maximum and minimum reading of the measuring device when the outer ring is turned one revolution.
Face runout with bore (S_d)	 	For face runout with bore, record the difference between the maximum and minimum reading of the measuring device when the inner ring is turned one revolution together with the tapered mandrel.
Variation of outside surface generatrix inclination with face for outer ring (S_D)		Variation of outside surface generatrix inclination with face for outer ring, record the difference between the maximum and minimum reading of the measuring device when the outer ring is turned one revolution along the reinforcement plate.

6. Load Rating and Life



6.1 Bearing Life

One of the most important factors when selecting bearings is the life of the bearing. Bearing life depends on the functions required of a machine.

Fatigue life ··· Life of the bearing in terms of material fatigue caused by rolling.

Lubrication life ··· Life of the bearing in terms of burning caused by deterioration of lubricant.

Sound life ··· Life of the bearing in terms of obstruction of bearing function caused by increase of turning sound.

Wear life ··· Life of the bearing in terms of obstruction of bearing function caused by wear of the internal parts, single bore diameter and outside diameter of the bearing.

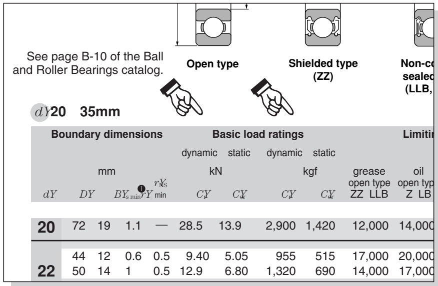
Precision life ··· Life of the bearing in terms of becoming unusable due to deterioration of the turning precision required by the machine.

In the case of fatigue life, the material becomes fatigued due to repeated load stress between the raceway and rolling elements, resulting in flaking. Duration of life can be predicted by statistical calculation. Generally speaking, fatigue life is treated as bearing life.

6.2 Basic Rating Life and Basic Dynamic Load Rating

When individual bearings of a group of the same type of bearing are turned under the same conditions, basic rating life is defined as the total number of times the bearing can be turned without flaking due to rolling fatigue in 90% (90% reliability) of the bearings.

Basic dynamic load rating expresses dynamic load capacity of rolling bearings, and therefore refers to a certain load, which provides basic rating life of one million revolutions. Basic dynamic load is expressed as pure radial load for radial bearings, and pure axial load for thrust bearings. Basic dynamic load rating C_r or C_a is given in the NTN catalog dimensions tables. ☞



See page B-10 of the Ball and Roller Bearings catalog.

Open type | Shielded type (ZZ) | Non-co sealed (LLB,

d 20 35mm

Boundary dimensions					Basic load ratings				Limiti	
					dynamic	static	dynamic	static		
mm					kN		kgf		grease	oil
d	D	B	$r_{s\,min}$	$r_{NS\,min}$	C_r	C_{or}	C_r	C_{or}	open type ZZ LLB	open typ Z LB
20	72	19	1.1	—	28.5	13.9	2,900	1,420	12,000	14,000
22	44	12	0.6	0.5	9.40	5.05	955	515	17,000	20,000
	50	14	1	0.5	12.9	6.80	1,320	690	14,000	17,000

Basic rating life is calculated by equation 6.1 or 6.2.

$$L_{10} = \left(\frac{C}{P}\right)^{p} \quad \text{.........................} \quad (6.1)$$

$$L_{10h} = \frac{10^6}{60n}\left(\frac{C}{P}\right)^{p} \quad \text{....................} \quad (6.2)$$

Where:

L_{10} : Basic rating life (10^6 revolutions)
L_{10h} : Basic rating life h (hours)
C : Basic dynamic load rating N {kgf}
C_r : Radial bearing
C_a : Thrust bearing
P : Dynamic equivalent load N {kgf}
P_r : Radial bearing
P_a : Thrust bearing
n : Rotational speed rpm
p : Ball bearing $p=3$
Roller bearing $p=10/3$

In equipment with several bearings, if the life of one develops rolling fatigue, it is considered to be the total life for all the bearings. Life can be calculated by equation 6.3.

$$L = \frac{1}{\left(\frac{1}{L_1} + \frac{1}{L_2} + \cdots + \frac{1}{L_n}\right)^{1/e}} \quad \cdots\cdots\cdots (6.3)$$

Where:

L : Total basic rating life as all bearings (h)

$L_1, L_2 \cdots L_n$: Basic rating life of individual bearings 1, $2 \cdots n$ (h)

e : Ball bearing········· $e=10/9$

Roller bearing······ $e=9/8$

In the case where load conditions vary at a fixed time percentage for a single bearing, life can be calculated by equation 6.4.

$$L_m = (\Sigma\, \phi_j / L_j)^{-1} \quad \cdots\cdots\cdots (6.4)$$

Where:

L_m : Total life of bearing

ϕ_j : Usage frequency of each condition ($\Sigma\, \phi_j = 1$)

L_j : Life under each condition

Life can also be calculated as bearing life of the entire machine by equation 6.3. To put life in more simple terms, in the case of a ball bearing for example, when load (dynamic equivalent load) is doubled, it has the effect of a cube, so life is reduced by 1/8, as shown by equation 6.2. When rotational speed is doubled, life is halved.

6.3 Adjusted Rating Life

If much is known about how the machine is being used, bearing life can be more accurately estimated under a variety of conditions. In other words, adjusted rating life can be calculated by equation 6.5.

$$L_{na} = a_1 \cdot a_2 \cdot a_3\, (C/P)^P \quad \cdots\cdots\cdots (6.5)$$

Where:

L_{na} : Adjusted rating life (10^6 revolutions)

a_1 : Life adjustment factor for reliability

a_2 : Bearing characteristic coefficient

a_3 : Usage condition coefficient

Life adjustment factor for reliability a_1

Bearing life is generally calculated at 90% reliability. In the case of bearings used in airplane engines, for example, reliability must however be above 90% if life directly affects the life of human beings. In this case, life is adjusted according to the values given in **Table 6.1**.

Table 6.1 Life adjustment factor for reliability a_1

Reliability %	L_n	Life adjustment factor for reliability a_1
90	L_{10}	1.00
95	L_5	0.62
96	L_4	0.53
97	L_3	0.44
98	L_2	0.33
99	L_1	0.21

Bearing characteristic coefficient a_2

Bearing characteristics concerning life vary if special materials, quality or manufacturing processes are used for bearings. In this case life is adjusted by the bearing characteristic coefficient a_2. Basic dynamic load rating given in the bearing dimensions table depends on the standard material and manufacturing method used by **NTN**, but $a_2 = 1$ is used under ordinary circumstances. $a_2 > 1$ is used for bearings made of special improved materials and manufacturing methods.

If bearings made of high carbon chrome are used at temperatures in excess of 120˚C for an extended period of time, with ordinary heat treatment, dimension variation is large. Bearings having undergone dimension stabilizing treatment (**TS treatment**) are therefore used in this case. Life is sometimes affected by a decrease in hardness due to treatment temperature. (See **Table 6.2**)

Table 6.2 Dimension stabilizing treatment

Code	Max. operating temp. (˚C)	Adjustment coefficient a_2
TS2	160	1.0
TS3	200	0.73
TS4	250	0.48

Life adjustment factor for operating condition a_3

Coefficient for adjusting life for lubrication conditions, rotational speed, running temperature, and other operating conditions. If lubrication conditions are favorable, a_3 is generally "1." If lubrication conditions are particularly good and other factors are normal, $a_3 > 1$ may be used.

Oppositely $a_3 < 1$ is used in the following cases:

- If lubrication oil viscosity is low (13 mm^2/s or less for ball bearing; 20 mm^2/s for roller bearing)
- Rotational speed is low (Rotational speed n by rolling element pitch circular d_p, $d_p \cdot n < 10,000$)
- If operating temperature is high (adjusted by **Fig. 6.1** due to decrease in hardness)

Items that consider coefficient a_2 by dimension stabilization treatment do not require adjustment of **Fig. 6.1** as long as each is used within maximum operating temperature.

Bearings are affected by various conditions other than these, but are not clarified as the a_3 coefficient. There is also the way of the a_{23} coefficient matching a_2 and a_3, but at the present there is need to overlap the data.

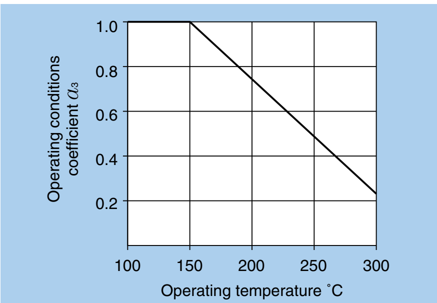


Fig. 6.1 Operating Conditions Coefficient According to Operating Temperature

In the case of an extremely large load, and there is danger of harmful plastic deformation developing on the contact surfaces of the rolling element and raceway, if P_r exceeds either C_{or} or 0.5 P_a in the case of radial bearings, or P_a exceeds 0.5 C_a in the case of thrust bearings, equations 6.1, 6.2 and 6.5 for calculating basic rating life cannot be applied.

6.4 Machine Applications and Requisite Life

When selecting bearings, you must select bearings that provide the life required for the machine. The general standards for life are given in **Table 6.3**.

6

6.5 Basic Static Load Rating

Bearing load where contact stress of maximum rolling element load is the following values is defined as basic static load rating.

Ball bearing	4 200MP	{428kgf/mm^2}
Roller bearing	4 000MPa	{408kgf/mm^2}

These values are the equivalent of the load where permanent set of approximately 0.0001 time the rolling element diameter is produced by the load in the area where the rolling elements make contact with the raceway surface. It is empirically known that the degree of deformation is as far as smooth rotation of the shaft is not impeded.

This basic static load rating is given in the dimension table as C_{or} and C_{oa} for radial and thrust bearings respectively.

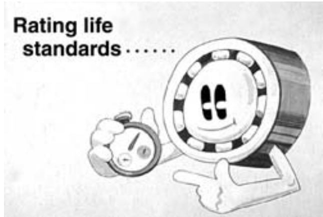

Table 6.3 Machine and Required Life (Reference)

Usage type	Machine and required life (reference) L_{10h}				×10³ hours
	~4	4~12	12~30	30~60	60~
Machine used occaisionally or for limited periods of time	Household electrical appliances Power tools	Farming equipment Office equipment			
Machine used occaisionally or for limited periods of time, but requires reliable operation	Medical equipment Measuring devices	Home air-conditioner Construction equipment Elevators Cranes	Cranes (sheave)		
Machine sometimes run for extended periods of time	Automobiles Motorcycles	Small motors Buses and trucks General gear-operated equipment Construction equipment	Machine tool spindles General purpose motors for factories Crushers Vibration screens	Important gear-operated equipment For use with rubber and plastic Calendar rollers Web presses	
Machines usually used more than 8 hours per day		Roller necks for rolling mills Escalators Conveyors Centrifuges	Passenger and freight vehicles (wheel) Air-conditioning equipment Large motors Compressor pumps	Locomotives (wheel) Traction motors Mining hoists Press flywheels	Pulp and papermaking equipment Ship propulsion units
Machines that operate 24 hours a day, for which breakdown cannot be permitted					Water works Mine drainage/ventilation equipment Power plant equipment

6.6 Allowable Static Equivalent Load

The quality of maximum static load for bearings is generally determined based on the value of the safety factor S_o.

$$S_o = \frac{C_o}{P_o} \quad \text{........................(6.6)}$$

Where:

S_o : Safety factor

C_o : Basic static load rating
(C_o or C_{oa}) N {kgf}

P_o : Static equivalent load
(P_{or} or P_{oa}) N {kgf}

For evaluation of S_o, the amount of permanent set is based on the previous definition of C_{or} and C_{oa}. It does not consider cracking of the rolling bearing ring or edge load of roller bearings. Evaluation must be empirically decided according to the machine and where it is used.

Table 6.4 Lower Limit Value of Safety Factor S_o

Operating conditions	Ball bearing	Roller bearing
If high rolling precision is required	2	3
If normal rolling precision is required (general purpose)	1	1.5

Remarks 1. "4" is used for the lower limit value of S_o for self-aligning thrust roller bearings.
2. "3" is used for the lower limit value of S_o for drawn cup needle roller bearings.
3. P_o is calculated taking shock load factor into consideration if there is vibration or shock load.
4. If a large axial load is applied to deep groove ball bearings or angular contact ball bearings, the fact that contact ellipse may ride up on the raceway surface must be considered.

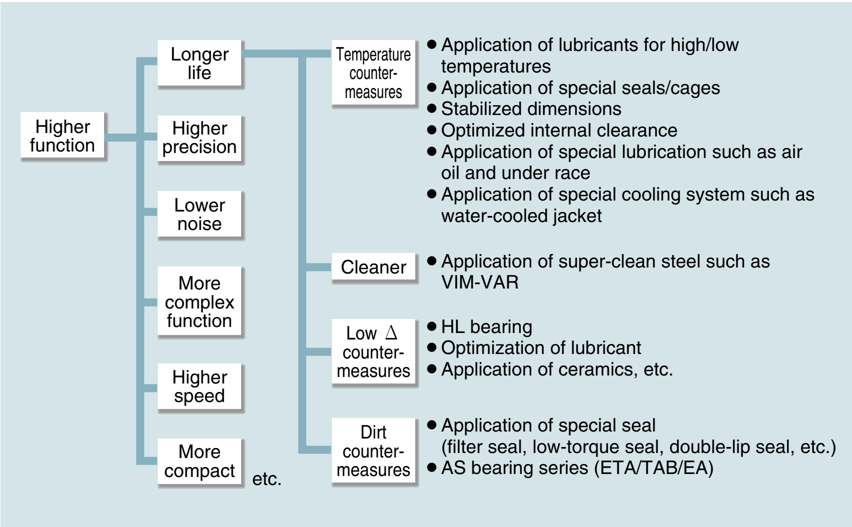
One-Point Advice

Bearing Tips

● Bearing with Higher Function and Longer Life

The life described in this handbook is basic rating life.

Bearings used for automobiles, steel equipment, machine tools, etc., must be designed to last a long time while providing the required function under limited conditions. **NTN** has the technologies required to do this. Some of them are given below.



7. Bearing Load

In order to calculate bearing life and safety factor, you must first know what sort of load is applied to the bearing. In other words, there are various types of loads and directions such as the weight of the rolling elements and the object supported by the bearing, conductivity of the belt and gears and the load produced when the machine performs work. These must be arranged in radial and axial load directions and calculated as a combined radial and axial load.

7.1 Load Used for Shafting

(1) Load factor

Depending upon the machine, a large load is produced by vibration and shock from theoretical calculation values. Taking advantage of the load factor, it is sometimes treated as actual load.

$$K = f_w \cdot K_c \quad \text{......(7.1)}$$

Where:
- K : Actual load placed on shaft N {kgf}
- f_w : Load factor (**Table 7.1**)
- K_c : Theoretical calculation value N {kgf}

Table 7.1 Load Factor fw f_w

Shock type	f_w	Machine
Almost no shock	1.0~1.2	Electric machinery, machine tools, measuring devices
Light shock	1.2~1.5	Railway cars, automobiles, rolling mills, metal machines, papermaking equipment, printing equipment, aircraft, textile machinery, electrical equipment, office equipment
Strong shock	1.5~3.0	Crushers, farming equipment, construction equipment, hoists

(2) Load on gears

When power is conveyed by gears, operating load differs according to the type of gear (spur, helical, bevel). As the simplest examples, spur and helical gears calculation is given here. Gear tangent load when shaft input torque is known:

$$K_t = \frac{2T}{D_p} \quad \text{......(7.2)}$$

Where:
- K_t : Gear tangent load N {kgf}
- T : Input torque N・mm {kgf・mm}
- D_p : Gear pitch round mm

When transfer power as shaft input is known:

$$K_t = \frac{19.1 \times 10^6 \cdot H}{D_p \cdot n} \quad \text{N}$$

$$K_t = \frac{1.95 \times 10^6 \cdot H}{D_p \cdot n} \quad \{\text{kgf}\} \quad \text{......(7.3)}$$

Where:
- n : Rotational speed rpm
- H : Transfer power kW

$$K_r = K_t \cdot \tan\alpha \quad \text{(Spur gear) ......(7.4)}$$

$$= K_t \cdot \frac{\tan\alpha}{\cos\beta} \quad \text{(Helical gear) ......(7.5)}$$

$$K_a = K_t \cdot \tan\beta \quad \text{(Helical gear) ......(7.6)}$$

Where:
- K_r : Radial load of gear
- K_a : Parallel load on gear shaft
- α : Pressure angle of gear
- β : Helix angle of gear

The following is calculated as a combined radial and axial load of radial load:

$$F_r = \sqrt{K_t^2 + K_t^2} \quad \text{......(7.7)}$$

F_r : Right angle load on gear shaft

When actually calculating bearing load, however, axial load Ka also affects radial load. It is therefore easier to calculate combined radial and axial load last.

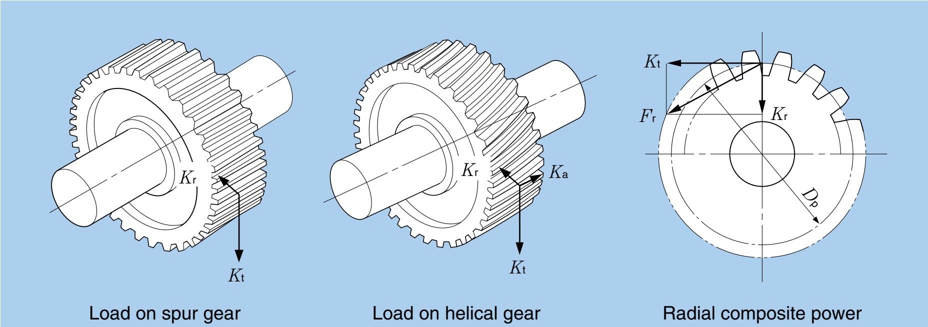


Fig. 7.1 Load on Gears

7

(3) Load on chain and belt shaft

The load on a sprocket or pulley when power is conveyed by a chain or belt is calculated as follows:

$$K_t = \frac{19.1 \times 10^6 \cdot H}{D_p \cdot n} \quad \text{N}$$

$$= \frac{1.95 \times 10^6 \cdot H}{D_p \cdot n} \quad \{\text{kgf}\} \quad \cdots\cdots\cdots\cdots(7.8)$$

Where:

K_t : Load on sprocket or pulley N {kgf}
H : Transfer power kW
D_p : Pitch diameter of sprocket or pulley mm

To account for initial tension applied to the belt or chain, radial load is calculated by equation 7.9.

$$K_r = f_b \cdot K_t \quad \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots(7.9)$$

Where:

K_r : Radial load
f_b : Chain/belt factor

Table 7.2 Chain/Belt Factor f_b

Type of chain/belt	f_b
Chain (single row)	1.2～1.5
V-belt	1.5～2.0
Timing belt	1.1～1.3
Flat belt (with tension pulley)	2.5～3.0
Flat belt	3.0～4.0

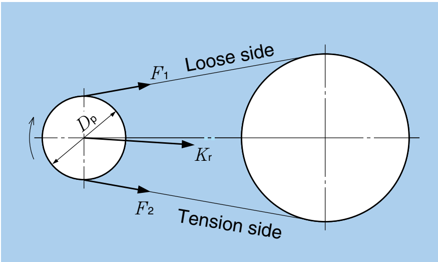

Fig. 7.2 Load on Chain/Belt

7

7.2 Bearing Load Distribution

Generally speaking, loads are placed on a shaft supported by bearings from various directions. The load is arranged as a radial or axial load depending on the size and direction of the load.

The following calculation procedure is modeled on the gears of the most common reduction gears. In **Fig. 7.3**, gear 1 is output (spur gear) and gear 2 is input (helical gear).

Where:

K_{t1}, K_{t2} : Gear tangential force (perpendicular to space)
K_{r1}, K_{r2} : Gear separation force
K_a : Gear axial force
r_1, r_2 : Gear pitch circular radius

$$K_{t1} = \frac{r_2}{r_1} \cdot K_{t2}$$

The correlation of K_t and K_r/K_a is in accordance with equations 7.4, 7.5 and 7.6.

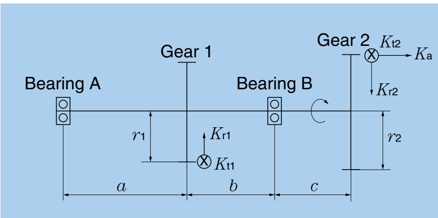

Fig. 7.3 Gear Load Transfer Example

(1) Load on bearing A

Load by K_{t1}/K_{t2}

$$F_{rAt} = \frac{b}{a+b} \cdot K_{t1} - \frac{c}{a+b} \cdot K_{t2}$$

Load by K_{r1}/K_{r2}/K_a

$$F_{rAr} = \frac{b}{a+b} \cdot K_{r1} + \frac{c}{a+b} \cdot K_{r2} + \frac{r_2}{a+b} \cdot K_a$$

Thus radial load on bearing A is:

$$F_{rA} = \sqrt{F_{rAt}^2 + F_{rAr}^2}$$

(2) Load on bearing B

(Axial load received by bearing B)

Load by K_{t1}/K_{t2}

$$F_{rBt} = \frac{a}{a+b} \cdot K_{t1} + \frac{a+b+c}{a+b} \cdot K_{t2}$$

Load by K_{r1}/K_{r2}/K_a

$$F_{rBr} = \frac{a}{a+b} \cdot K_{r1} - \frac{a+b+c}{a+b} \cdot K_{r2} - \frac{r_2}{a+b} \cdot K_a$$

Radial load on bearing B:

$$F_{rB} = \sqrt{F_{rBt}^2 + F_{rBr}^2}$$

Axial load on bearing B is K_a.

When one shaft is supported by three bearings, and there is a lot of distance between bearings, bearing load is calculated as 3-point support. A specific calculation example is extremely complicated, so the bearing load equation is given for a simple load example only. (See **Table 7.3**)

In actuality, various complicated loads are applied. We have therefore clearly indicated load direction and calculated these for each load individually. Finally we calculated bearing life as combined radial and axial load.

Table 7.3 Bearing Load of 3-Point Support Bearings

Load and moment direction	Bearing load
	$R_B = -\frac{\ell_o(2\ell_2+\ell_1)}{2\ell_1\ell_2}W$ $R_A = \frac{(\ell_1+\ell_2+\ell_o)W-\ell_2 R_B}{\ell_1+\ell_2}$ $R_C = -\frac{\ell_o W+\ell_1 R_B}{\ell_1+\ell_2}$
	$R_B = -\frac{(2\ell_2+\ell_1)M_o}{2\ell_1\ell_2}$ $R_A = \frac{M_o-\ell_2 R_B}{\ell_1+\ell_2}$ $R_C = -\frac{M\ \ell_1 R_B}{\ell_1+\ell_2}$
	$R_B = \frac{\ell_3(\ell_1^2+2\ell_1\ell_2-\ell_3^2)W}{2\ell_1^2\ell_2}$ $R_A = \frac{(\ell_1+\ell_2-\ell_3)W-\ell_2 R_B}{\ell_1+\ell_2}$ $R_C = \frac{\ell_3 W-\ell_1 R_B}{\ell_1+\ell_2}$
	$R_B = \frac{(-\ell_1^2-2\ell_1\ell_2+3\ell_3^2)M_o}{2\ell_1^2\ell_2}$ $R_A = \frac{M_o-\ell_2 R_B}{\ell_1+\ell_2}$ $R_C = -\frac{M_o+\ell_1 R_B}{\ell_1+\ell_2}$

7

7.3 Equivalent Load

7.3.1 Dynamic Equivalent Load

In many cases, both radial and axial loads are applied to bearings at the same time. In such a case, this is converted to pure radial load for radial bearings, and pure axial load for thrust bearings. A hypothetical load which provides an equal life is called a "dynamic equivalent load."

(1) Dynamic equivalent radial load

Dynamic equivalent radial load is calculated by equation 7.10.

$$P_r = XF_r + YF_a \quad \cdots\cdots\cdots\cdots (7.10)$$

Where:

P_r : Dynamic equivalent radial load N {kgf}
F_r : Radial load N {kgf}
F_a : Axial load N {kgf}
X : Radial load factor
Y : Axial load factor

The values of XY are given in the dimensions table of the catalog.

(2) If bearing has a contact angle

A bearing having a contact angle such as angular contact ball bearings and tapered roller bearings have their pressure cone apex at a position off center of the bearing. When a radial load is placed on the bearing, a component force is produced in the axial direction. This force is generally referred to as "induced thrust," and its magnitude is calculated by equation 7.11.

$$F_a = \frac{0.5F_r}{Y} \quad \cdots\cdots\cdots\cdots (7.11)$$

Where:

F_a : Axial direction component force (induced thrust) N {kgf}
F_r : Radial load N {kgf}
Y : Axial load factor

These bearings are generally used in symmetrical arrangement. A sample calculation is given in **Table 7.4.**

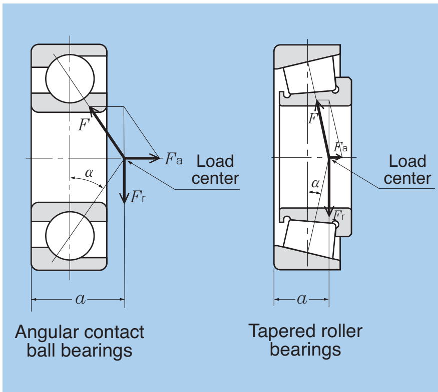

Fig. 7.4 Pressure Cone Apex and Axial Component Force

Table 7.4 Sample Calculation of Axial Component Force

Bearing arrangement	Load conditions	Axial load	Dynamic equivalent radial load
	$\frac{0.5F_{rI}}{Y_I} \leqq \frac{0.5F_{rII}}{Y_{II}} + F_a$	$F_{aI} = \frac{0.5F_{rII}}{Y_{II}} + F_a$	$P_{rI} = XF_{rI} + Y_I\left(\frac{0.5F_{rII}}{Y_{II}} + F_a\right)$
		$F_{aII} = \frac{0.5F_{rII}}{Y_{II}}$	$P_{rII} = F_{rII}$
	$\frac{0.5F_{rI}}{Y_I} > \frac{0.5F_{rII}}{Y_{II}} + F_a$	$F_{aI} = \frac{0.5F_{rI}}{Y_I}$	$P_{rI} = F_{rI}$
		$F_{aII} = \frac{0.5F_{rI}}{Y_I} - F_a$	$P_{rII} = XF_{rII} + Y_{II}\left(\frac{0.5F_{rI}}{Y_I} - F_a\right)$

Remarks 1. F_{rI} and F_{rII} are applied to bearings I and II respectively, as well as axial load F_a.
2. Applies when preload is 0.

7.3.2 Static Equivalent Load

Static equivalent load refers to pure radial or axial load that provides the same amount of permanent set as the maximum permanent set produced in the contact surface of the rolling elements and raceway when receiving the maximum load under actual load conditions.

This is used for bearing selection under load conditions where the bearing is stationary or turns at extremely low speed.

(1) Static equivalent radial load

The larger one of the values calculated by equations 7.12 and 7.13 is used for static equivalent radial load of radial bearings.

$$P_{or}=X_oF_r+Y_oF_a \quad \text{........................(7.12)}$$
$$P_{or}=F_r \quad \text{...................................(7.12)}$$

Where:

P_{or} : Static equivalent radial load N {kgf}
F_r : Radial load N {kgf}
F_a : Axial load N {kgf}
X_o : Static radial load factor
Y_o : Static axial load factor

The values of X_o and Y_o are given in the dimensions table of the catalog. ☞

	3	1	1	11	0.35	1.74	0.96	0.104

7.4 Allowable Axial Load

A radial bearing can also receive an axial load, but there are various limits according to the type of bearing.

(1) Ball bearings

When an axial load is applied to ball bearings such as deep groove ball bearings and angular contact ball bearings, contact angle changes along with load. When the permissible range is exceeded, contact ellipse of the balls and raceway surface protrudes from the groove.

As shown in **Fig. 7.5**, the contact surface is elliptical with a major axis radius of a. The critical load where the contact ellipse doesn't go over the edge of the groove is the maximum allowable axial load (even if the contact ellipse doesn't go over the edge of the groove, allowable axial load must be P_{max} < 4 200 MPa). This load differs for the bearing internal clearance, groove curvature, groove edge, etc. If it is also carrying a radial load, critical load is checked by maximum rolling element load.

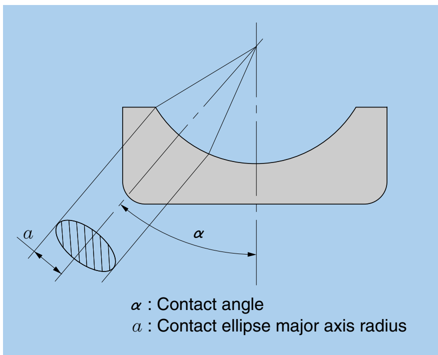

Fig. 7.5 Contact Ellipse

7

(2) Tapered roller bearings

Tapered roller bearings receive an axial load at both the raceway surface and where the roller end faces come in contact with the cone back face rib. Thus, by increasing contact angle α , the bearing becomes capable of receiving a large axial load. Because the roller end faces slide along the surface of the cone back face rib, this is limited according to rotational speed and lubrication conditions. This is generally checked by the value of PV, which takes advantage of sliding speed of surface pressure of the sliding surface.

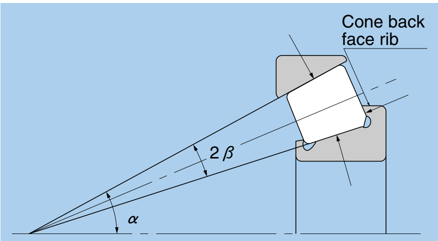

Fig. 7.6 Tapered Roller Bearing

(3) Allowable axial load for cylindrical roller bearings

Cylindrical roller bearings with inner and outer rings having ribs are capable of simultaneously receiving a radial load and a certain amount of axial load. In this case, allowable axial load is decided by heat and wear of the sliding surface between the roller end faces and rib.

Based on experience and testing, allowable load in the case where a centric axial load is to be supported can be approximated by equation 7.14.

$$P_t = k \cdot d^2 \cdot P_z \quad \text{……………………} \quad (7.14)$$

Where:

P_t : Allowable axial load when turning N {kgf}

k : Factor decided according to bearing internal design (see **Table 7.5**)

d : Bearing bore mm

P_z : Allowable surface pressure of rib MPa {kgf/mm²} (see **Fig. 7.7**)

If axial load is however larger than radial load, normal rolling of the rollers is negatively affected, so be careful not to allow $F_{a\ max}$ to be exceeded. Lubrication conditions, mounting dimensions and precision must also be taken into consideration.

Table 7.5 Value of Factor k and Allowable Axial Load ($F_{a\ max}$)

8. Fits

8.1 Bearing Fits

The inner and outer rings of bearings support a load that rotates, and are therefore mounted on the shaft and housing. In this case, fitting of the inner ring with the shaft, and outer ring with the housing differs according to nature of the load, assembly of the bearing and ambient environment, depending upon whether the fit is provided with clearance or interference. The three basic types of fitting are as follows:

(1) Clearance fit

Mounted with clearance in the fit.

(2) Transition fit

Mounted with both clearance and interference in the fit.

(3) Interference fit

Mounted in if fixed position with interference in the fit.

The most effective method of mounting a bearing to support a load is to provide interference by fastening with an interference fit. There are also advantages in providing clearance, such as mounting, dismounting and absorption of expansion and contraction of the shaft and housing due to change in temperature. If you do not provide interference that matches the load, creep may be produced by rotation. As shown in **Fig. 8.1**, if there is creep in the clearance difference of the fit that turns while receiving the load, slipping may be produced by the difference in the inner ring bore and circumference length, resulting in abnormal heat, abrasion and powder which negatively affect the bearing. Even if there is no clearance, creep may occur if the load is large. You should therefore decide the proper fit using **Table 8.2** as a guideline.

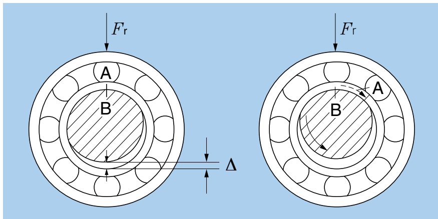

Fig. 8.1 Bearing Creep

Table 8.1 Nature and Fit of Radial Loads

Diagram	Rotation division		Nature of load	Fit
Static load 		Inner ring: rotating Outer ring: stationary	Inner ring turning load Outer ring static load	Inner ring: Interference fit Outer ring: Clearance fit
Unbalanced load 		Inner ring: stationary Outer ring: rotating		
Static load 		Inner ring: stationary Outer ring: rotating	Inner ring static load Outer ring turning load	Inner ring: Clearance fit Outer ring: Interference fit
Unbalanced load 		Inner ring: rotating Outer ring: stationary		

Interference or clearance range on the other hand is decided by dimension tolerance of the bearing, shaft and housing. Fit therefore requires sufficient consideration.

8.2 Fit Selection

Proper fit selection is dependent upon thorough analysis of bearing operating conditions:

- **Shaft and housing material, wall thickness, rigidity and finished surface precision**
- **Machinery operating conditions (nature and magnitude of load, rotating speed, temperature, etc.)**

The basic philosophy for fit concerns whether it is the inner or outer ring that turns. Fit is decided by which of the bearing rings the load moves along, and is as given in **Table 8.1**.

The relationship of dimension tolerance for the housing and shaft on which the bearing is to be mounted is as shown in **Fig. 8.2**.

Some of the general fitting criteria for various types of bearings under various operating conditions is given in **Figs. 8.2** through **8.4**. For details, see "A45 - 53 of the NTN Ball and Roller Bearings catalog".

Table 8.2 Tolerance Class of Shaft Used for Radial Bearings (Class 0, 6X, 6)

Conditions		Ball bearings		Cylindrical roller bearings Tapered roller bearings		Self-aligning roller bearings		Shaft tolerance class	Remarks
		Shaft diameter (mm)							
		Over	Up to	Over	Up to	Over	Up to		
Cylindrical bore bearing (Class 0, 6X, 6)									
Inner ring rotating load or indeterminate direction load	Light or ❶ fluctuating load	—	18	—	—	—	—	h5	js5, k5 and m5 may be used in place of js6, k6 and m6 if more precision is required.
		18	100	—	40	—	—	js6	
		100	200	40	140	—	—	k6	
		—	—	140	200	—	—	m6	
	Normal load ❶	—	18	—	—	—	—	js5	Internal clearance variation according to fit doesn't have to be considered for single row angular contact ball bearings and tapered roller bearings. You may therefore use k6 and m6 in place of k5 and m5.
		18	100	—	40	—	40	k5	
		100	140	40	100	40	65	m5	
		140	200	100	140	65	100	m6	
		200	280	140	200	100	140	n6	
		—	—	200	400	140	280	p6	
		—	—	—	—	280	500	r6	
	Heavy or ❶ shock load	—	—	50	140	50	100	n6	Use bearing with internal clearance larger than CN clearance bearing.
		—	—	140	200	100	140	p6	
		—	—	200	—	140	200	r6	
Inner ring static load	Inner ring must be able to move easily on shaft.	All shaft diameters						g6	Use g5 if more precision is required. F6 is also OK to facilitate movement in the case of large bearings.
	Inner ring does not have to be able to move easily on shaft.	All shaft diameters						h6	Use h5 if more precision is required.
Centric axial load		All shaft diameters						js6	Shaft and bearing are not generally fixed by fit.
Tapered bore bearing (class 0) (W/ adapter or withdrawal sleeve)									
All loads		All shaft diameters						h9/IT5 ❷	H10/IT7 may also be used with conductive shaft ❷

❶ Light, normal and heavy load refer to basic dynamic radial load rating of 6% or less, above 6% to 12% and less, and over 12% for dynamic equivalent radial load.

❷ Shaft circular and cylindrical tolerance values are given for IT5 and IT7.

Remarks: This table applies to steel solid shafts.

Table 8.3 Tolerance Class of Housing Bore Used for Radial Bearings (Class 0, 6X, 6)

Conditions				Tolerance class of housing bore	Remarks
Housing	Load type, etc.		Transfer in axial ❸ direction of outer ring		
Integral or two-piece housing	Outer ring static load	All load types	Able to transfer.	H7	G7 may be used for large bearings or when there is a large temperature difference between outer ring and housing.
		❶ Light or normal loads ❶	Able to transfer.	H8	—
		Temperature of shaft and inner ring become high.	Easily able to transfer.	G7	F7 may be used for large bearings or when there is a large temperature difference between outer ring and housing.
Integral housing		Requires precision rotation with light or normal loads.	As a rule, not able to transfer.	K6	Primarily applies to roller bearings.
			Able to transfer.	JS6	Primarily applies to ball bearings.
		Requires silent running.	Able to transfer.	H6	—
	Indeterminate direction load	Light or normal loads	Able to transfer.	JS7	JS6 and K6 may be used in place of JS7 and K7 if more precision is required.
		Normal or heavy loads ❶	As a rule, not able to transfer.	K7	
		Large shock loads	Not able to transfer	M7	—
	Outer ring rotating load	Light or fluctuating loads	Not able to transfer	M7	—
		Normal or heavy loads	Not able to transfer	N7	Primarily applies to ball bearings.
		Heavy or large shock loads with thin wall housing	Not able to transfer	P7	Primarily applies to roller bearings.

❶ In accordance with ❶ of **Table 8.2**.
❸ Data for non-separable bearings is given separately according to whether or not the outer ring is capable of transfer in the axial direction.
Remarks 1. This table applies to cast iron or steel housing.
2. If only centric axial load is applied to the bearing, select a tolerance class that provides the outer ring with clearance in the radial direction.

Table 8.4 Tolerance Class of Shaft Used for Thrust Bearings (Class 0, 6X, 6)

Conditions		Shaft diameter (mm)		Shaft tolerance class	Remarks
		Over	Up to		
Centric axial load (thrust bearings in general)		All shaft diameters		js6	Also used for h6.
Combined radial and axial load (self-aligning thrust roller bearing)	Inner ring static load	All shaft diameters		js6	—
	Inner ring rotating or indeterminate direction load	—	200	k6	js 6, k6 and m6 may be used in place of k6, m6 and n6 respectively.
		200	400	m6	
		400	—	n6	

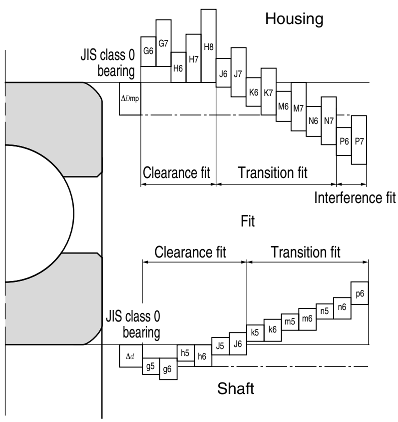

Fig. 8.2 Bearing Fit Status

8.3 Fit Calculation

As was previously stated, standards for bearing fits have already been set, but problems such as creep, bearing ring cracking and premature flaking may occur depending on conditions such as actual assembly, load and temperature. The following items must be checked if interference is necessary.

(1) Load and interference

When a radial load is placed on a bearing, interference between the inner ring and shaft is reduced. Thus, interference varies according to the size of the load. The required interference is calculated by the following equation. (The equation supposes that a solid steel shaft is used.)

When $F_r \leqq 0.3\,C_{or}$

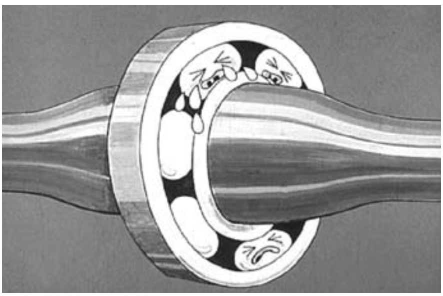
$$\left.\begin{aligned}\Delta d_F &= 0.08\,(d \cdot F_r/B)\ 1/2\ \text{N}\\ &= 0.25\,(d \cdot F_r/B)\ 1/2\ \{\text{kgf}\}\end{aligned}\right\} \cdots (8.1)$$

When $F_r > 0.3\,C_{or}$

$$\left.\begin{aligned}\Delta d_F &= 0.02\,(F_r/B)\ \text{N}\\ &= 0.2\ (F_r/B)\ \{\text{kgf}\}\end{aligned}\right\} \cdots (8.2)$$

Where

Δd_F : Required effective interference according to radial load (μm)
d : Bearing bore (mm)
B : Inner ring width (mm)
F_r : Radial load N {kgf}
C_{or} : Basic static load rating N {kgf}



(2) Temperature and interference

The temperature of the shaft and housing generally rises while the bearing is operating. As a result, interference between the inner ring and shaft is reduced. In this case, interference is calculated by the following equation.

$$\Delta d_r = 0.0015 \cdot d \cdot \Delta T \qquad (8.3)$$

Where:

Δd_r : Required effective interference according to temperature difference (μm)
ΔT : Difference between bearing temperature and ambient temperature (˚C)
d : Bearing bore (mm)

(3) Interference and surface roughness of fit surface

Fit surface roughness of the shaft and housing is crushed to a certain extent, reducing interference by that amount. The amount that interference is reduced differs according to roughness of the fit surface, but this is generally compensated somewhat when calculating inner ring expansion and outer ring contraction factors.

(4) Maximum interference

Tensile stress is produced in the bearing ring mounted on the shaft when interference is provided. If excessive interference is applied, the bearing ring could be cracked or life reduced. The upper limit value for interference is generally 1/1000 of the shaft diameter or less.

In the case of heavy or shock loads, calculate fit stress with detailed analysis. It is generally safe as long as 13 kgf/mm^2 is not exceeded for bearing steel, or 18 kgf/mm^2 for carburizing steel.

8.4 Pressure of Fit Surface

The pressure that is produced on the fit surface and equation for calculating maximum stress are given in **Table 8.5**.

Mean groove diameter for the inner and outer rings of the bearing can be approximated from **Table 8.6**.

Interference that effectively works on fit surface pressure, i.e. "effective interference Δ_{deff}, is smaller than interference Δ_d (theoretical interference) calculated from dimension measurements of the shaft or bearing bore. This is primarily due to the influence of finish surface roughness. The following reduction amounts must therefore be anticipated.

Grinding shaft : 1.0 ～ 2.5 μm
Turning shaft : 5.0 ～ 7.0 μm

Table 8.5 Pressure and Maximum Stress of Fit Surface

Fit conditions		Equation	Symbols (Unit: N {kgf} , mm)
Fit surface pressure MPa {kgf / mm^2}	Fit of hollow steel shaft and inner ring	$P = \frac{E}{2}\frac{\Delta_{deff}}{d}\left[1-\left(\frac{d}{D_i}\right)^2\right]$	d : Shaft diameter, inner ring bore d_o : Hollow shaft bore D_i : Inner ring mean groove diameter Δ_{deff} : Effective interference E : Elastic factor = 208 000 MPa {21 200 kgf/mm^2} 	Fit of hollow steel shaft and inner ring	$P = \frac{E}{2}\frac{\Delta_{deff}}{d}\frac{[1-(d/D_i)^2][1-(d_o/d)^2]}{[1-(d_o/D_i)^2]}$	
	Fit of steel housing and outer ring	$P = \frac{E}{2}\frac{\Delta_{Deff}}{D}\frac{[1-(D_o/D)^2][1-(D/D_h)^2]}{[1-(D_o/D_h)^2]}$	DS : Housing bore, bearing outside diameter D_o : Outer ring mean groove diameter D_h : Housing outside diameter Δ_{Deff} : Effective interference Max. stress MPa {kgf / mm^2}	Fit of shaft and inner ring	$\sigma_t max = P\frac{1+(d/D_i)^2}{1-(d/D_i)^2}$	Tangent stress of inner ring bore is maximum.
	Fit of housing and outer ring	$\sigma_t max = P\frac{2}{1-(D_o/D)^2}$	Tangent stress of outer ring bore is maximum.

Table 8.6 Mean Groove Diameter

Bearing type		Mean groove diameter	
		Inner ring (D_i)	Outer ring (D_o)
Deep groove ball bearing	All types	$1.05\frac{4d+D}{5}$	$0.95\frac{d+4D}{5}$
Cylindrical roller bearing ❶	All types	$1.05\frac{3d+D}{4}$	$0.98\frac{d+3D}{4}$
Self-aligning roller bearing	All types	$\frac{2d+D}{3}$	$0.97\frac{d+4D}{5}$

d: Inner ring bore mm　　D: Outer ring outside diameter mm
❶ Values given for mean groove diameter are those for double ribs.

8.5 Force Required for Press Fit and Drawing

The force required to pressure fit the inner ring on the shaft and the outer ring on the housing, or for drawing the inner ring off the shaft or outer ring off the housing is calculated by equations 8.4 and 8.5.

For shaft and inner ring:

$$K_d = \mu \cdot P \cdot \pi \cdot d \cdot B \quad \text{(8.4)}$$

For housing and outer ring:

$$K_D = \mu \cdot P \cdot \pi \cdot D \cdot B \quad \text{(8.5)}$$

Where:

K_d : Inner ring pressure fit or drawing force N {kgf}
K_D : Outer ring pressure fit or drawing force N {kgf}
P : Fit surface pressure MPa {kgf/mm^2} (See **Table 8.5**)
d : Shaft diameter, inner ring bore (mm)
D : Housing bore, outer ring outside diameter (mm)
B : Inner or outer ring width
μ : Sliding friction coefficient (See **Table 8.7**)

Table 8.7 Sliding Friction Coefficient for Pressure Fit and Draw

Item	μ
When pressure fitting inner (outer) ring on cylindrical shaft (hollow)	0.12
When drawing inner (outer) ring off cylindrical shaft (hollow)	0.18
When pressure fitting inner ring on tapered shaft or sleeve	0.17
When drawing inner ring off tapered shaft	0.14
When pressure fitting sleeve on shaft or bearing	0.30
When drawing sleeve off shaft or bearing	0.33

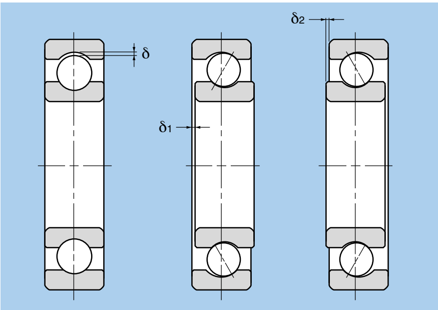
8

9. Bearing Internal Clearance and Preload

9.1 Bearing Internal Clearance

As shown in **Fig. 9.1**, prior to mounting the bearing on the shaft and housing, when either the inner or outer ring is in a fixed position the amount of transfer when the counterpart is moved in the radial or axial direction is called radial internal clearance or axial internal clearance. This internal clearance is standardized by ISO 5753 (JIS B 1520). Radial internal clearance for deep groove ball bearings is given as an example in **Table 9.1**. For details, see "A54 - 65 of the "**NTN** Ball and Roller Bearings catalog".

Measurement load is of course applied when measuring clearance. Measurement load and correction values have been established as shown in **Table 9.2** due to elastic deformation caused by measurement load, particularly for ball bearings.



Radial internal clearance = δ
Axial internal clearance = $\delta_1 + \delta_2$

Fig. 9.1 Bearing Internal Clearance

Table 9.2 Radial Internal Clearance Correction Values for Measurement Load (Deep Groove Ball Bearing) Unit: μm

9.2 Internal Clearance Selection

During operation, clearance largely affects bearing performance such as bearing life, heat, vibration and sound. It is therefore necessary to select the clearance that matches operating conditions. If the clearance is theoretically slightly negative, optimal bearing life values are given, but if the clearance is further to the negative side, life decreases radically. Operating conditions are likely to fluctuate during operation due to a variety of factors. Generally speaking, you should therefore select initial bearing internal clearance so that operating clearance is slightly larger than 0.

Internal clearance during operation is calculated by the following equation:

$$\delta_{eff} = \delta_o - (\delta_f + \delta_t) \quad \cdots\cdots(9.1)$$

Where:

δ_{eff} : Operating clearance (mm)
δ_o : Bearing initial internal clearance (mm)
δ_f : Internal clearance reduction due to interference (mm)
δ_t : Internal clearance reduction due to the difference in temperature of the inner and outer rings (mm)

(1) Internal clearance reduction due to interference

If the inner and outer rings are mounted on the shaft or housing with interference, the inner ring expands, the outer ring contracts, and internal clearance decreases by that amount.

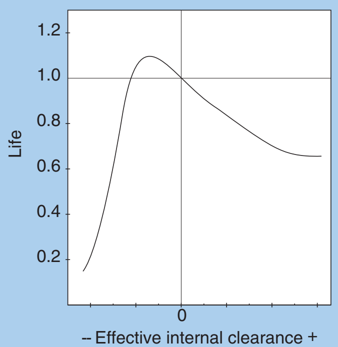

Fig. 9.2 Internal Clearance and Life

The amount of reduction differs according to the type of bearing, shape of shaft or housing, dimensions and material, but it is approximately 70 - 90% of effective interference.

$$\delta_f = (0.70 \sim 0.90)\ \Delta_{eff} \quad \cdots\cdots(9.2)$$

δ_f : Internal clearance reduction due to interference (mm)
Δ_{eff} : Effective interference (mm)

To calculate more precisely, you can take material, shape and dimensional shape of each part into consideration. Dimension tolerance is supposed to be normal distribution, and is generally calculated by 3σ.

(2) Internal clearance reduction due to the difference in temperature of the inner and outer rings

As for bearing temperature during operation, temperature of the outer ring is generally 5 - 10˚C lower than that of the inner ring or rolling elements. When heat radiation of the housing and shaft are connected to the heat source, temperature difference further increases. Internal clearance decreases by precisely the amount of the inner and outer rings expand due to the difference in temperature.

$$\delta_t = \alpha \cdot \Delta T \cdot D_o \quad \cdots\cdots(9.3)$$

δ_t : Internal clearance reduction due to the difference in temperature of the inner and outer rings
α : Coefficient of linear expansion for bearing materials 12.5×10^{-6}/˚C
ΔT : Difference in temperature of the inner and outer rings (˚C)
D_o : Raceway diameter of the outer ring (mm)

Raceway diameter of outer ring is approximated by the following equation.

For ball bearings and self-aligning roller bearings

$$D_o = 0.2\,(d + 4D) \quad \cdots\cdots(9.4)$$

For ball bearings and self-aligning roller bearings

$$D_o = 0.25\,(d + 3D) \quad \cdots\cdots(9.5)$$

d : Bearing bore diameter
D : Bearing outside diameter

Note that the formula in item 9. 2 only applies to copper bearings, shafts and housings.

9.3 Preload

Bearings are used with minimal clearance during operation. Bearings used in pairs such as angular contact ball bearings and tapered roller bearings are sometimes used with negative clearance in the axial direction, depending upon the application. This condition is called "preload." This means there is elastic contact between the rolling elements and raceway surface.

The following effects are obtained as a result:

- Bearing rigidity increases.
- Suitable for high-speed rotation.
- Rotation precision and positioning precision is enhanced.
- Vibration and noise are suppressed.
- Smearing which can cause the rolling element to slip is reduced.
- Fretting produced by external vibration is prevented.

Excessive preload however invites life reduction, abnormal heating, and increase of rotating torque.

(1) Preload method

There are two ways to provide preload: one is fixed position preload where the opposing bearing is fastened in a fixed position and a certain preload is applied by adjusting bearing width dimensions, spacer and shim dimensions, and the other is fixed pressure preload where preload is applied by a spring.

Concrete examples of the preload methods are given in **Table 9.3**.

Standard preload amounts are set for duplex angular contact ball bearings. (See NTN catalog) ☞

●Bearing Internal Clearance and Preload

See page A-64 of the Ball and Roller Bearings catalog.

Table 8.13 The normal preload of duplex arrangement angular contact ball bearings

Table 9.3 Preload Method and Characteristics

Preload method	Preload basic pattern	Applicable bearings	Objective of preload	Method and preload amount	Usage example
Fixed position preload		Angular contact ball bearings	Maintain shaft precision, prevent vibration, enhance rigidity	Certain amount of preload is provided by planar difference of inner/outer ring width or spacer.	Grinders Turning machines Milling machines Measuring devices
		Tapered roller bearings Thrust ball bearings Angular contact ball bearings	Enhance rigidity of bearing.	Preload is provided by loosening screws. Amount of preload is set with measuring starting torque of bearing or transfer distance of bearing rings.	Turning machines Milling machines Automobiles Differential pinions Printing presses Wheels
Fixed pressure preload		Angular contact ball bearings Deep groove ball bearings Tapered roller bearings (high speed)	Maintain precision and prevent vibration/noise without changing preload by load, temperature, etc.	Preload is provided by coil springs, disc springs, etc. Deep groove ball bearings 4～10 d N 0.4～1.0 d {kgf} d : Shaft diameter (mm)	Internal cylindrical grinding machines Electric motors Small high-speed shafts Tension reels

(2) Preload and rigidity

When an axial load is placed on a bearing, in many cases rigidity is enhanced and preload is applied to reduce displacement of the bearing in the axial direction. Let's therefore consider the correlation of load and displacement when outside pressure is placed on a bearing to which preload is applied.

Displacement of various bearings by elastic deformation is shown in **Fig. 9.3**.

As shown in the figure, when the inner ring tightly adheres in the axial direction, preload load F_o is applied, producing δ_o elastic deformation. When external force F_a is added, displacement increases by exactly δ_a for bearing Ⅰ, and decreases for bearing Ⅱ. At this time bearings Ⅰ and Ⅱ become balanced by the loads of $F_Ⅰ$ and $F_Ⅱ$ respectively. The amount of displacement of bearing Ⅰ when external force F_a is applied without preload is δ_b, which is quite a bit larger than δ_a. In other words, this shows that rigidity is enhanced by preload.

10. Allowable Speed

As rotational speed of the bearing becomes larger, bearing temperature rises due to friction produced inside the bearing, producing damage such as seizure, making continued stable operation impossible. Allowable speed is the rotational speed limit at which the bearing can perform. Allowable speed differs according to bearing type, dimensions, precision, clearance, type of cage, load conditions, lubrication conditions, and various other factors.

The catalog dimensions table gives allowable speed standards for grease and oil lubrication, but allowable speed is based on the following conditions: ☞

- Bearing of proper internal design and clearance is correctly mounted.
- Suitable lubricant is used, and is properly replenished or replaced.
- Normal operating temperature under normal load conditions ($P \leqq 0.09\,C_r$, $F_a/F_r \leqq 0.3$).

Correction is necessary if load is large (see **Figs. 10.1** and **10.2**). For sealed bearings, speed is determined by peripheral speed of the seal contact section. If a radial bearing is used for a vertical shaft, there are disadvantages concerning lubrication maintenance and cage guide, so about 80% of the allowable speed is suitable. If using in excess of the allowable speed, you must reconsider bearing specifications and lubrication conditions.

11. Bearing Characteristics

11.1 Friction

One characteristic of rolling bearings is that they produce less friction than sliding bearings, particularly starting friction. Friction of rolling bearings involves a variety of factors.

- Friction that accompanies rolling (load)
- Sliding friction between cage and rolling elements, and cage and guide surface
- Sliding friction between roller end faces and guide rib
- Friction of lubricant or sealing device

The friction factor for rolling bearings is generally expressed by the following equation.

$$\mu = \frac{2M}{Pd} \quad \text{.................................} \quad (11.1)$$

Where:
μ : Friction factor
M : Friction moment N·mm {kgf·mm}
P : Bearing load N {kgf}
d : Bearing bore mm

The dynamic friction factor for rolling bearings is affected by various factors as mentioned before. Dynamic friction factor also differs according to rotational speed as well as bearing type. Values are generally taken from **Table 11.1**

11

Table 11.1 Friction Factor for Bearings

Bearing type	Friction factor $\mu \times 10^{-3}$
Deep groove ball bearings	1.0～1.5
Angular contact ball bearings	1.2～1.8
Self-aligning ball bearings	0.8～1.2
Cylindrical roller bearings	1.0～1.5
Needle roller bearings	2.0～3.0
Tapered roller bearings	1.7～2.5
Self-aligning roller bearings	2.0～2.5
Thrust ball bearings	1.0～1.5
Thrust roller bearings	2.0～3.0

11.2 Temperature Rise

Almost all friction loss is converted to heat inside the bearing, causing the temperature of the bearing itself to rise. The amount of heat produced by friction moment is expressed by equation 11.2.

$$Q = 0.105 \times 10^{-6}\, M \cdot n \quad \text{N}$$
$$= 1.03 \times 10\text{-}6^{-6}\, M \cdot n \quad \{\text{kgf}\} \quad \text{......}(11.2)$$

Where:
Q : Amount of heat produced kW
M : Friction moment N·mm {kgf·mm}
n : Rotational speed of bearing rpm

Bearing temperature is determined by the balance of the amount of heat produced and the amount of heat released.

In most cases temperature rises sharply during the initial stages of operation, and then stabilizes to a somewhat lower temperature after a certain amount of time elapses. The amount of time it takes to reach this constant temperature differs according to various conditions such as bearing size, type, rotational speed, load, lubrication, and heat release of the housing. If constant temperature is never reached, it is assumed that there is something wrong. Possible causes are as follows:

- Insufficient bearing internal clearance or excessive preload.
- Bearing is mounted improperly.
- Excessive axial load due to heat expansion or improper mounting of the bearing.
- Excess/lack of lubricant, improper lubricant.
- Heat is being generated from the sealing device.

Data concerning temperature rise due to load or rotational speed is provided for your reference. (See **Figs. 11.1** and **11.2** on the following page)

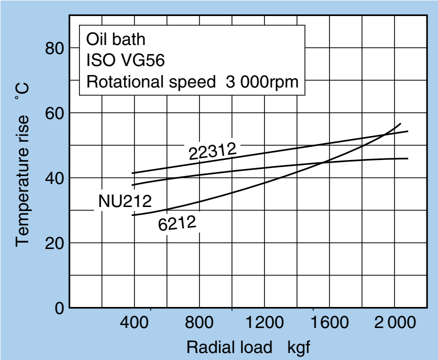

Fig. 11.1 Radial Load and Temperature Rise

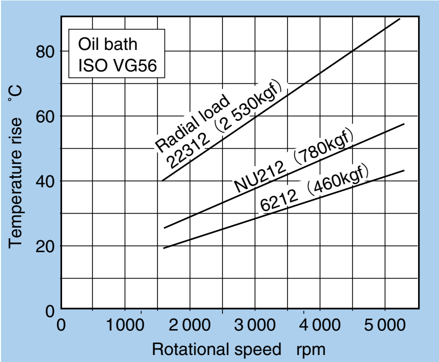

Fig. 11.2 Rotational Speed and Temperature Rise

11.3 Sound

When the inner or outer ring of the bearing turns, the rolling elements roll along the raceway surface accompanying the cage, thus producing various sounds and vibrations. In other words, vibration and sound is produced according to shape and roughness of the rolling surface and sliding parts, and the lubrication status.

With improved quality in various fields, including the data equipment field, the demand for less vibration and sound has escalated in recent years. It is rather difficult to express sound, but a list of typical abnormal sounds produced by bearings is given in **Table 11.2**.

One-Point Advice

Bearing Tips

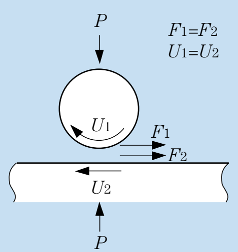
●What is rolling friction?

They say it is theoretically extremely difficult to measure pure rolling friction where difference in speed of two surfaces must be zero.

In actuality, however, the influence of pure rolling friction is extremely small compared to other factors involved in rolling bearings (such as friction between the cage and rolling elements, agitation resistance of the lubricant), and is usually ignored.

Friction is however produced between two surfaces by rolling, and there is an intimate connection between rolling and sliding friction.

Various past experiments suggest that the rolling friction factor is approximately between 0.00001 and 0.001.



Rolling friction measurement model diagram

Sound	Characteristics	Related factors
Swoosh Swoop	Sound quality does not change when rotational speed changes (dirt). Sound quality changes when rotational speed changes (Flaw).	Dirt. Surfaces of raceway, balls or rollers is rough. Damage of raceway, balls or roller surface.
Sssss	Small bearing	Surface roughness of raceway, balls or rollers.
Hiss	Produced intermittently as a rule.	Contact with labyrinth. Contact with cage and seal.
Growl (Moaning sound)	Size and height changes when rotational speed changes. Loud sound is produced at certain rpm. Sound becomes louder and softer. Sounds sometimes like siren or whistle.	Resonance, improper fit (improper shaft shape). Deformation of bearing rings. Chatter of raceway surface, balls or rollers (in the case of large bearings, a small amount of chatter is normal).
Scratch	Sensed when turned manually.	Scratching of raceway surface (regular). Scratching of balls or rollers (irregular). Dirt, deformation of bearing rings (negative clearance in places).
Roll Rumble	Large bearings, Small bearings: Continuous sound according to high speed.	Scratching of raceway surface, surface of balls or rollers.
Whirr	Stops as soon as power is turned off.	Electromagnetic sound of motor.
Crackle	Occurs irregularly (Doesn't change when rotational speed is altered). Primarily applies to small bearings.	Dirt in bearing.
Pitter-patter, Flap flap, Flutter	Tapered roller bearings, Large bearings, Small bearings: Regular continuous sound at high speed.	Clear sound from cage is normal. Improper grease at low temperature → grease should be soft. Operation with cage pocket wear, insufficient lubrication, insufficient bearing load.
Click Clack	Noticeable at low speed. Continuous sound at high speed.	Sound of impact in cage pocket; insufficient lubrication. Eliminated by decreasing clearance or applying preload. Mutual impact of full complement rollers.
Crack Clang	Loud metallic impact sound. Low-speed, thin-wall large bearings (TTB), etc.	Sound of rolling elements popping.
Urrr	Primarily cylindrical roller bearings; changes when rotational speed is altered. Sounds metallic if loud. Stops temporarily when grease is replenished.	Large consistency of lubricant (grease). Excessive radial clearance. Insufficient lubrication.
Squeak Screech	Sound of crunching between metals. High-pitched sound.	Crunching between rollers and rib surface of roller bearings. Insufficient lubrication
Pip pop	Occurs irregularly in small bearings.	Sound of air bubbles in the grease being smashed.
Krak	Squeaking sound produced irregularly.	Sliding of fit sections. Squeaking of mounting surfaces.
Sound pressure is generally too large.		Surface of raceway, balls or roller is rough. Deformation of raceway surface, balls or rollers due to wear. Clearance has been enlarged due to wear.

11

12. Lubrication

The objective of lubricating a bearing is to form a film of oil on the rolling and sliding surfaces to prevent metal parts from making direct contact with each other. Lubrication provides the following effects.

- Reduces friction and wear
- Discharges friction heat
- Extends bearing life
- Prevents rust
- Prevents foreign material from getting inside

In order to get the most from the lubricant, you must choose a lubricant and lubrication method that suits your usage conditions, and must make use of sealing devices for preventing dirt from getting in and lubricant from leaking out.

12.1 Grease Lubrication

Grease is widely used because it is easy to handle, it facilitates sealing device design, and is the most economical lubricant. Lubrication methods include sealed bearings where the grease is sealed inside the bearing in advance, and the method of filling an open bearing and housing with grease, and replenishing or replacing the grease at fixed intervals.

(1) Types of grease

Grease is hardened to a semi-solid by adding thickener to base oil (mineral oil or synthetic fluid), and then augmented by additives such as oxidation stabilizers, extreme-pressure additives and rust-preventive agents.

The nature of the grease therefore varies according to the types and combinations.

An example is given in **Table 12.1**.

Table 12.1 Grease Types and Characteristics

Name	Lithium grease			Non-soap grease	
Thickener	Li soap			Bentone, silica gel, urea, carbon black, fluorine compounds, etc.	
Base oil	Mineral oil	Diester oil	Silicon oil	Mineral oil	Synthetic oil
Dropping point (˚C)	170 ～ 190	170 ～ 190	200 ～ 250	250 or more	250 or more
Operating temperature range (˚C)	-30 ～ +130	-50 ～ +130	-50 ～ +160	-10 ～ +130	-50 ～ +200
Mechanical stability	Superior	Good	Good	Good	Good
Pressure resistance	Good	Good	Poor	Good	Good
Water resistance	Good	Good	Good	Good	Good
Applications	Largest range of applications. All-purpose grease for rolling bearings.	Superior low-temperature and friction characteristics. Suitable for small and miniature bearings.	Suitable for high and low temperatures. Has low oil film strength, and is therefore not suitable for large loads.	Can be used in a wide range of temperatures, from low to high. Exhibits superior heat, cold and chemical resistance characteristics through proper combination of base oil and thickener. All-purpose grease for rolling bearings.	

Consistency is the standard used by JIS for expressing softness of grease. The smaller the consistency number, the softer and more fluid is the grease. (See **Table 12.2**)

Main grease brands and nature table are given in **Table 12.3** on page 60. Nature is lost by mixing greases of different types. This must be avoided.

NLGI consistency No.	JIS (ASTM) 60-times mixing consistency	Application
0	355～385	Concentrated greasing
1	310～340	Concentrated greasing
2	265～295	General purpose, sealed bearings
3	220～250	General purpose, high temperature
4	175～205	Special purpose

■**Solid grease (for polylube bearing)**

Solid grease is a mixture of ultra high polymer polyethylene and lubricating grease, which is hardened by heating after sealing in the bearing. The lubricant is maintained inside polyethylene, so there is minimal leaking of the lubricant. The lubricant itself has no fluidity, so spot-pack specifications are characterized by small torque. This is also connected with preventing dirt from entering and soiling of the surrounding area by grease discharge. If used at high temperatures, however, discharge of oil increases, thus shortening lubrication life. Precautions therefore must be taken for high-speed operation or when using in high temperatures. Packing examples are shown in **Figs. 12.1** and **12.2**. **Photographs 12.1** and **12.2** were taken with the aid of an electron microscope.

12

(2) Grease filling and replacement

The amount of grease it takes to fill the bearing differs according to housing design, space volume, rotational speed, and grease type. The standard for filling is 30 to 40% of the bearing space volume, and 30 to 60% of space volume for the housing.

Use less grease if rotational speed is high, or you want to hold down the temperature. Too much grease could cause temperature to rise, grease to leak, or performance to decrease due to deterioration. Be careful not to overfill the bearing with grease. Approximate value for space volume in the bearing is calculated by equation 12.1.

$$V = K \cdot W \quad \cdots\cdots (12.1)$$

Where:

V : Space volume of an open bearing (approximate value) (cm^3)

K : Bearing space factor (see **Table 12.4**)

W : Bearing mass (kg)

Performance of grease deteriorates with the passing of time. Grease must therefore be replenished at suitable intervals. Replenishment interval differs according to bearing type, dimensions, rotational speed, temperature and type of grease. The standard is given in **Fig. 12.3**. This is however under normal operating conditions. Grease is also largely affected by temperature. When the bearing temperature rises above 80˚C, make the replenishment interval 1/1.5.

Table 12.4 Bearing Space Factor K

Bearing type	Cage type	K

12.2 Oil Lubrication

Along with facilitating lubrication of rolling and sliding parts inside the bearing, oil lubrication functions to eliminate heat produced from inside and outside the bearing. There are various methods of providing oil lubrication. The main ones are given in **Table 12.5**.

Table 12.5 Oil Lubrication Method

Lubrication method	Example	Lubrication method	Example
Oil bath lubrication ● Oil bath lubrication is the most common method of lubrication and is widely used for low to moderate rotation speed applications. ● For horizontal shaft applications, oil level should be maintained at approximately the center of the lowest rolling element, according to the oil gauge, when the bearing is at rest. For vertical shafts at low speeds, oil level should be maintained at 50 - 80% submergence of the rolling elements.		Disc lubrication ● With this method, part of the disc mounted on the shaft is submerged in oil, and the bearing is lubricated by oil springing upward.	Oil spray lubrication ● With this method, an impeller or similar device mounted on the shaft draws up oil and sprays it on the bearing. This method can be used at considerably high speeds.		Oil mist lubrication ● The bearing is lubricated by oil mist propelled by pressurized air. ● Low resistance of lubricating oil makes this method suitable for high-speed rotation. ● Produces a lot of atmospheric pollution.	Drip lubrication ● With this method, oil collected above the bearing is allowed to drip down into the bearing where it changes to a mist as it comes in contact with the rolling elements in the housing. Another version allows only a slight amount of oil to pass through the bearing. ● Used at relatively high speeds for light to moderate loads. ● In most cases, oil volume is a few drops per minute.		Air-oil lubrication ● With this method, the minimum required amount of oil is measured out and fed by compressed air to each bearing at the optimal interval. ● Bearing temperature can be minimized by constant supply of fresh lubricating oil to the bearing, coupled with the cooling effect of compressed air. ● Only an extremely small amount of oil is required, resulting in less pollution released into the atmosphere.	Circulating lubrication ● Used for bearing cooling applications or for automatic oil supply systems in which oil supply is centrally located to many portions. ● Features clean maintenance of lubricating oil if the lubrication system is provided with a cooler to cool the lubricating oil, or a filter is used. ● Provided on mutually opposing side relative to the oil inlet and outlet of the bearing so that the oil reliably lubricates the bearing.		Oil jet lubrication ● Lubricates by high-pressure injection of oil from the side of the bearing. Provides high reliability under harsh conditions such as high speeds and high temperatures. ● Used for lubricating main bearings in jet engines, gas turbines and other high-speed equipment. ● Under-race lubrication for machine tools is one example of this type of lubrication.	
12

(1) Selection of lubricating oil

Various mineral oils such as spindle oil, machine oil and turbine oil are used as lubricating oil. For high temperature of 150˚C and above, and low temperatures of -30˚C and below, however, synthetic oils such as diester oil, silicone oil and fluorocarbon oil are used. Viscosity of lubricating oil is an important characteristic that determines lubricating performance. If viscosity is too low, oil film does not form sufficiently, resulting in damage to the bearing surface. On the other hand, if viscosity is too high, viscosity resistance becomes large, causing temperature to rise and friction loss to increase. Generally, the higher the rotational speed, the lower the viscosity should be, and the heavier the load is, the higher viscosity should be.

The viscosity required for lubrication of rolling bearings at this operating temperature is given in **Table 12.6**. The correlation of viscosity and temperature is given in **Fig. 12.4**. **Table 12.7** gives standards for selecting lubricating oil viscosity according to bearing operating conditions.

Table 12.6 Viscosity Required for Bearings

Bearing type	Viscosity mm^2/s
Ball bearings, cylindrical roller bearings, needle roller bearings	13
Self-aligning roller bearings, tapered roller bearings, thrust needle roller bearings	20
Self-aligning thrust roller bearings	30

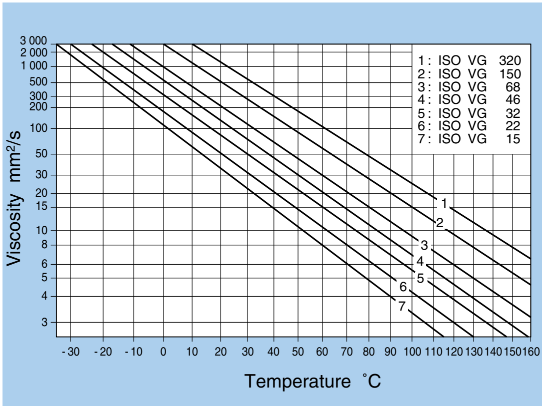

Fig. 12.4 Correlation of Temperature and Viscosity of Lubricating Oil

Table 12.7 Standard for Selecting Lubricating Oil

Bearing operating temperature ˚C	*dn* Value	ISO viscosity grade of lubricating oil (VG)		Applicable bearings
		Normal load	Heavy or shock load	
—30～ 0	Up to allowable rpms	22, 32	46	All types
0～ 60	15 000 Up to	46, 68	100	All types
	15 000 ～80 000	32, 46	68	All types
	80 000 ～150 000	22, 32	32	All bearings except thrust ball bearings
	150 000～500 000	10	22, 32	Single row radial ball bearings, cylindrical roller bearings
60～100	15 000 Up to	150	220	All types
	15 000 ～80 000	100	150	All types
	80 000 ～150 000	68	100, 150	All bearings except thrust ball bearings
	150 000～500 000	32	68	Single row radial ball bearings, cylindrical roller bearings
100 ～150	Up to allowable rpms	320		All types
0～ 60	Up to allowable rpms	46, 68		Self-aligning roller bearings
60～100	Up to allowable rpms	150		

Remarks 1: When the lubrication method is oil bath or circulating lubrication.

(2) Oil quantity

When lubrication is forcibly fed to the bearing, the amount of heat generated from the bearing, etc. equals the sum of the radiant heat given off by the housing and heat given off by the oil. The quantity of oil required for a standard housing is calculated by the equation 12.2.

$$Q=K\cdot q \quad \cdots\cdots\cdots\cdots\cdots\cdots (12.2)$$

Where

Q : Quantity of oil supplied per bearing (cm³/min)

K : Allowable oil temperature rise factor (see **Table 12.8**)

q : Oil quantity according to diagram (cm³/min) (**Fig. 12.5**)

In the case of actual operation, it is safe to adjust the oil supply quantity to meet the amount that is adequate for the actual situation because the sum of the radiant heat varies depending on the housing shape by referring to the calculated value as a guideline. Assuming that the oil carries away all the generated heat in **Fig. 12.5**, the oil supply quantity should be calculated as the shaft diameter d = 0.

The oil replacement limit in the oil bath lubrication may vary depending on the using condition, oil quantity or lubricant type. It is recommended to replace the oil around once a year if the oil is used in the range lower than 50˚C, and at least every three months in the case of range between 80 and 100˚C.

Discharge oil temperature minus supplied oil temperature (˚C)	K
10	1.5
15	1
20	0.75
25	0.6

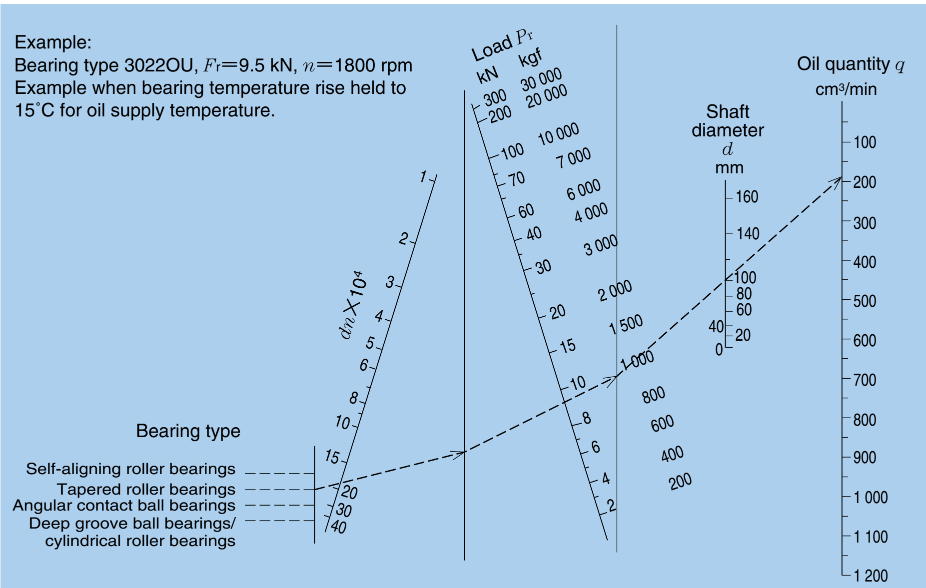

Fig. 12.5 Oil Supply Quantity Diagram

13. External Bearing Sealing Devices

The objective of sealing devices is to prevent lubricant from leaking out of the bearing and prevent dirt and water from getting inside the bearing. Sealing devices work well to seal and make the bearing dust-proof for various operating conditions. Sealing devices are durable - they produce little friction and no abnormal heat. They are also good for applications requiring ease of assembly.

Sealing devices are roughly divided into non-contact seals and contact seals. Seals can also be used in various combinations, the most common of which are given in **Table 13.1**.

Type	Seal construction	Name	Seal characteristics
Non-contact seal		Clearance seal	Extremely simple seal design with small radial clearance.
		Oil groove seal (Oil grooves on housing side)	Several concentric oil grooves are provided on the housing inner diameter to greatly improve the sealing effect. When the grooves are filled with lubricant, the intrusion of contaminants from the outside is prevented.
		Oil groove seal (Oil grooves on shaft and housing side)	Oil grooves are provided on both the shaft outer diameter and housing inner diameter to form a more efficient seal.
		Radial labyrinth seal	Seal where labyrinth passages are formed in the radial direction. Used for housing vertically divided in two. Provides better sealing than axial labyrinth seals.
		Internal slinger in housing	The housing is provided with a slinger. The centrifugal force of the turning slinger prevents lubricant from leaking out.
Contact seal		Z grease seal	Contact seal has a Z-shaped cross-section. The hollow portion is packed with grease to form a grease seal. Often used for plummer blocks.
	  	Oil seal	Contact seals are generally used as oil seals. The type and dimensions are standardized by ISO 6194 (JIS B 2402). Sealing effect is enhanced by a ring-shaped spring mounted on the lip of the oil seal, which presses the lip edge against the shaft surface. If the bearing and oil seal are close to each other, heat produced from the oil seal may cause internal clearance of the bearing to be insufficient. Select bearing internal clearance with proper regard for heat produced from the oil seal due to peripheral speed. Depending upon orientation, the seal functions to prevent lubricant from leaking out the bearing, or foreign matter from getting inside.
Combination seals		Oil groove seal + slinger + Z grease seal	In order to enhance performance, some Z grease seals include an oil groove seal and slinger. The figure on the left shows triple seal construction for prevention intrusion of foreign matter by seal orientation. Used for mining equipment and plummer blocks and other places exposed to excessive dust.

14. Bearing Materials

14.1 Bearing ring and Rolling element materials

When a rolling bearing turns while receiving a load, a lot of stress is repeatedly placed on the small contact surface of the bearing rings and rolling elements, and the bearing must maintain high precision while rotating. That means bearing materials must satisfy the following demands.

- Must be hard.
- Rolling fatigue life must be long.
- Wear must be slight.
- Must be shock-resistant.
- Dimensions must not vary largely with the passing of time.
- Must be economical and easy to machine.

Among the things that affect rolling fatigue life most are non-metallic debris in steel. Various steel manufacturing methods have been developed to reduce non-metallic debris, which have contributed to enhancing life.

The same materials are generally used for bearing rings and rolling elements, especially high carbon chrome bearing steel. The chemical constituents of the various types of steel have been standardized by ISO 683 (JIS G 4805). The composition table for the most frequently used material, SUJ2, is given in **Table 14.1**.

Table 14.1 High Carbon Chrome Bearing Steel (ISO 683 (JIS G 4805))

Steel type code	Chemical composition %					
	C	Si	Mn	P	S	Cr
SUJ2	0.95~ 1.10	0.15~ 0.35	Max. 0.50	Max. 0.025	Max. 0.025	1.30~ 1.60

In addition to this, there is shock-resistant carburized steel whereby the surface is carbon tempered and the core softened to provide it with toughness, high-speed steel used at high temperatures, stainless steel which emphasizes corrosion resistance, ceramics with small specific gravity for ultra high speed, and plastics used in liquids, each of which is used according to objective.

Dimensions of the same bearing steel are subject to change in high temperatures in excess of 120˚C. Development of all kinds of bearings including bearings that are treated to resist dimension change and those whose life has been extended by modified heat treatment and carbon-nitride surface treatment.

14.2 Cage materials

Cages function to correctly retain rolling elements as the bearing turns, but they must also be strong enough to withstand vibration and shock loads while turning, and must be able to withstand operating temperature of the bearing. The cages must also be lightweight and produce little friction between rolling elements and bearing rings.

Pressed cages of cold or hot-rolled steel sheets are often used for small and medium-sized bearings, but stainless steel is also used, depending upon the purpose. Machine structure carbon steel, high strength brass and aluminum alloys are also used for machined cages such as large-sized bearings. If cage strength is required, heat-treated materials of nickel chrome molybdenum (SNCM) are used, and copper and silver plating is used for enhancing lubrication characteristics. In recent years injection molded heat-resistant polyamide reinforced with glass or carbon fibers have come to be used. Plastic cages are lightweight, corrosion-resistant, and have superior attenuation and lubrication characteristics. Teflon cages are sometimes used for high temperatures.

15. Shaft and Housing Design

Bearing performance is largely affected by inclination, deformation and creep according to shaft and housing design. The following are therefore very important.

- Bearing arrangement selection and method of fastening the bearing suited to the selected arrangement
- Suitable shaft and housing fillet radius and shoulder height dimensions, squareness, runout
- Dimensions, shape precision and roughness of fitted parts
- Outer diameter of shaft and housing (including thickness variation)

15.1 Fixing of Bearings

When fastening a bearing to the shaft or housing, the bearing must be fixed in the axial direction as well as fastening by interference with some exceptions. In the case of an axial load, bearing rings may move due to shaft flexure when cylindrical roller bearings are used as the floating side bearing, and must therefore be fixed in the axial direction. Shaft shoulder height should not exceed groove bottom.

The most common methods of fastening are shown in **Fig. 15.1**.

Inner ring fixing	Outer ring fixing	Fixing with snap ring
		The most common fixing method is to fasten the edge of the bearing ring to the shaft or housing shoulder by nuts or bolts.		Construction is simplified by using a snap ring, but dimensions related to bearing mounting such as interference with chamfers must be considered. Snap rings are not suitable if high precision is required and a large axial load is applied to the snap ring.

Fixing by adapter sleeve	Fixing by withdrawal sleeve
	When mounting on a cylindrical shaft using an adapter sleeve or withdrawal sleeve, the bearing can be fixed in the axial direction. In the case of an adapter sleeve, the bearing is fixed in place by frictional force between the inside of the sleeve and the shaft.	

Fig. 15.1 Examples of Bearing Fixing Methods

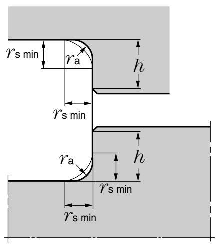
15.2 Bearing Fitting Dimensions

The shaft and housing shoulder height (h) should be larger than the bearing's maximum allowable chamfer dimensions ($r_{s\,max}$), and the shoulder should be designed so that it directly contacts the flat part of the bearing end face. The fillet radius must be smaller than the bearing's minimum allowable chamfer dimension ($r_{s\,min}$) so that it does not interfere with bearing seating. Dimensions are given in **Table 15.1**.

If shaft fillet R is increased in order to enhance shaft strength, and the shaft shoulder dimension is too small, mount with a spacer between the shaft shoulder and bearing. (See **Fig. 15.2**)

Grinding undercut is needed if the shaft is to be grind-finished. Undercut dimensions are given in **Table 15.2**.

Table 15.1 Shoulder Height and Fillet Radius



Unit: mm

$r_{s\,min}$	$r_{as\,max}$	h (Min.) General ❶	h (Min.) Special ❷
0.05	0.05	0.3	
0.08	0.08	0.3	
0.1	0.1	0.4	
0.15	0.15	0.6	
0.2	0.2	0.8	
0.3	0.3	1.25	1
0.6	0.6	2.25	2
1	1	2.75	2.5
1.1	1	3.5	3.25
1.5	1.5	4.25	4
2	2	5	4.5
2.1	2	6	5.5
2.5	2	6	5.5
3	2.5	7	6.5
4	3	9	8
5	4	11	10
6	5	14	12

15.3 Shaft and Housing Precision

Precision required for normal operating conditions is given in **Table 15.3**, and allowable bearing misalignment for various types of bearings is given in **Table 15.4**.

Using bearings in excess of these limits, bearing life decreases and could damage the cage, etc. Pay special attention to rigidity of the shaft and housing, mounting error resulting from machining precision, and then select bearing type carefully.

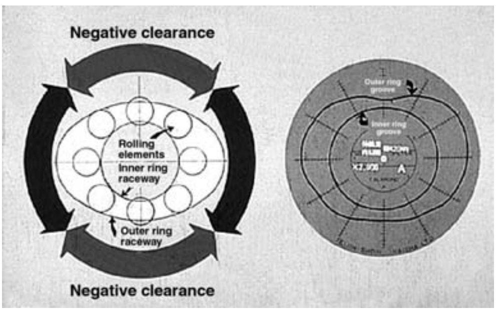
Table 15.3 Shaft and Housing Precision

Item		Shaft	Housing
Dimension precision		IT6 (IT5)	IT7 (IT5)
Circularity (max) Cylindricity		IT3	IT4
Shoulder runout tolerance		IT3	IT3
Fit surface roughness	Small bearings	0.8a	1.6a
	Medium to large bearings	1.6a	3.2a

Reference: In the case of precision bearings (precision given on P4 and P5), precision must be kept down to approx. 1/2 for circularity and cylindricity.

Table 15.4 Allowable Bearing Misalignment

Allowable misalignment	
Deep groove ball bearings	1/1 000～1/300
Angular contact ball bearings	
Single row	1/1 000
Double row	1/10 000
Back-to-back	1/10 000
Face-to-face	1/1 000
Cylindrical roller bearings	
Bearing Series 2, 3, 4	1/1 000
Bearing Series 22, 23, 49, 30	1/2 000
Tapered roller bearings	
Single row and back-to-back	1/2 000
Face-to-face	1/1 000
Needle roller bearings	1/2 000
Thrust bearings (excluding self-aligning thrust roller bearings)	1/10 000
Allowable alignment	
Self-aligning ball bearings	1/20
Self-aligning roller bearings	1/50～1/30
Self-aligning thrust roller bearings	1/30



15

16. Handling

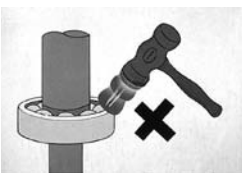
Rolling bearings are precision parts, and must be handled with care to ensure their precision. The following care should be taken:

- Bearings must be kept clean. Dirt affects wear and noise. Be careful of dirt in the air as well.
- Do not expose to strong shocks. Doing so could cause dents or crack the raceway surface. Do not drop or strike with a hammer.
- In order to prevent rust, do not handle with your bare hands. Should be coated with rust preventative, and stored in package in max. relative humidity of 60%.

16.1 Mounting

Remove all dirt, spurs, metal shavings, etc., from the shaft, housing, related parts and mounting fixtures before mounting the bearing. Check the dimension precision, shape precision, and roughness of the mounting section and make sure they are within tolerance. Leave the bearing in its packaging until you are ready to mount it.

In the case of oil lubrication, or even when using grease lubrication, if there is danger of destroying effectiveness of the lubricant by mixing with rust preventatives, remove the rust preventative with detergent oil prior to mounting. If you plan to apply grease after cleaning the bearing, you should dry the bearing somewhat before applying grease. If the bearing is to be inserted on the shaft or in the housing, you must apply equal pressure to the entire circumference of the bearing rings (inner and outer) while inserting. Inserting while applying force to just one part will cause the ring to become cocked to one side. If you apply force to the ring that is not to be inserted, load is applied via the rolling elements. This could dent the raceway surface, and should absolutely be avoided. Inserting bearing rings by striking directly with a hammer could crack or break the ring, as well as dent it.



(1) Mounting cylindrical bore bearings

As shown in **Fig. 16.1**, bearings with comparatively low interference are press or hammered into place while applying an equal load to the entire circumference of the bearing by positioning the guide on the edge of the bearing ring to be fit. If mounting the inner and outer rings simultaneously, press fit evenly using a metal block as shown in **Fig. 16.2**. In either case, be careful the bearing does not become misaligned when you begin mounting. In some cases a guide is used to prevent misalignment. If interference of the

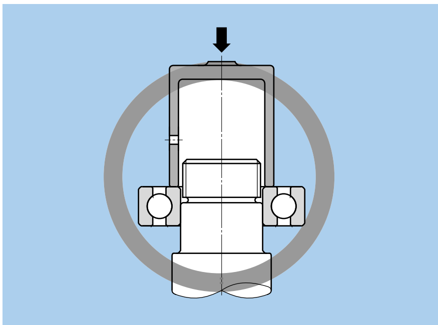


Fig. 16.1 Inner Ring Press Fitting

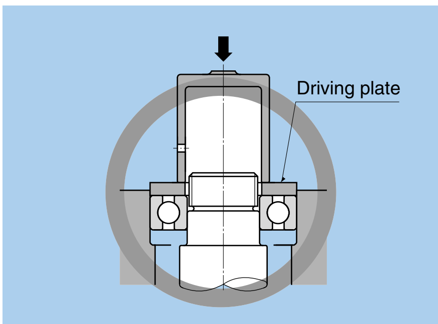

Fig. 16.2 Inner/Outer Ring Simultaneous Press Fitting

16

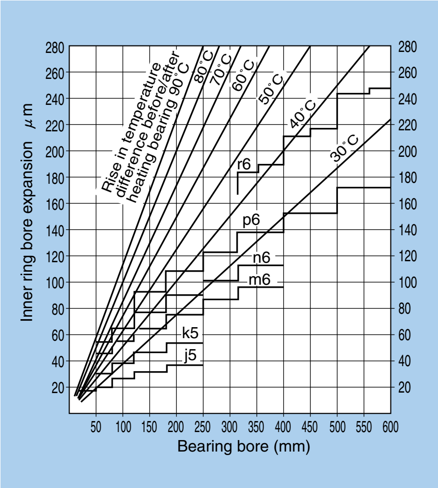

Fig. 16.3 Heating Temperature Required for Heat Fit of Inner Ring

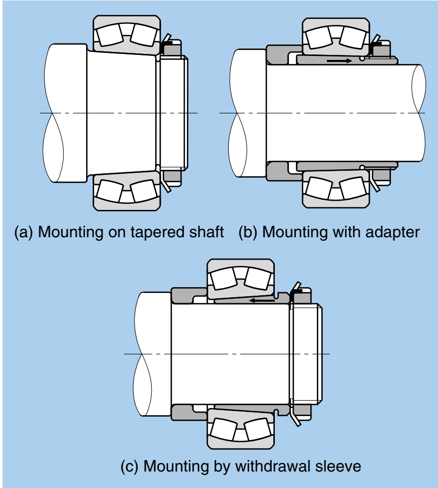

Fig. 16.4 Mounting by Locknut

inner ring is large, the bearing is generally heated to make the inner ring expand can easily be inserted on the shaft. The amount of expansion according to temperature difference of the bearing bore is shown in **Fig. 16.3**.

Dipping in clean heated oil is the most common method of heating the bearing (this cannot be done with grease sealed bearings). You must also be careful not to heat the bearing in excess of 120˚C. In addition to this there is heating in air in a thermostatic chamber, and inductance heaters are used for inner ring separation (required demagnetization) such as cylindrical rollers. After inserting the heated bearing on the shaft, the inner ring must be pressed against the shaft shoulder until the bearing cools in order to prevent clearance from developing.

(2) Mounting tapered bore bearings

A tapered shaft or adapter/withdrawal sleeve is used for small bearings with tapered bore. The bearings are driven into place with a locknut. (See **Fig. 16.4**)

Large bearings require a lot of driving force,

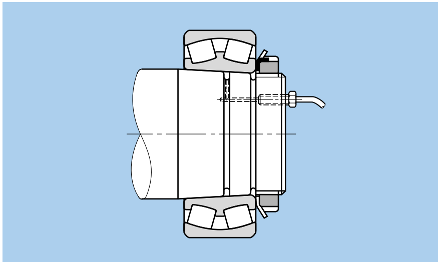

Fig. 16.5 Mounting by Oil Injection

and are mounted by hydraulic pressure. **Fig. 16.5** shows the bearing directly mounted on a tapered shaft. With this method, high-pressure oil is sent to the fit surface (oil injection) in order to reduce friction of the fitting surface and tightening torque of the nut. In addition to this, bearings can be mounted by a hydraulic nut or sleeve using hydraulic pressure. In the case of bearings mounted in this fashion, interference is increased and radial internal clearance is decreased by driving the tapered surface in the axial direction. You can estimate interference by measuring the amount the clearance decreases. To measure radial internal clearance of self-aligning roller bearings, let the roller settle into their correct positions and insert a thickness gauge in between the rollers and outer ring where there is no load (**Fig. 16.6**). At this time, it is important to measure with the rollers still. You can also obtain the proper interference by measuring the amount of drive in the axial direction instead of the amount of radial internal clearance reduction.

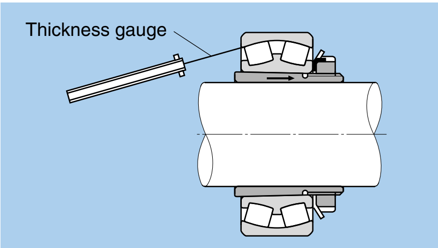

Fig. 16.6 Measuring Internal Clearance of Self-Aligning Roller Bearings

(3) Mounting outer rings

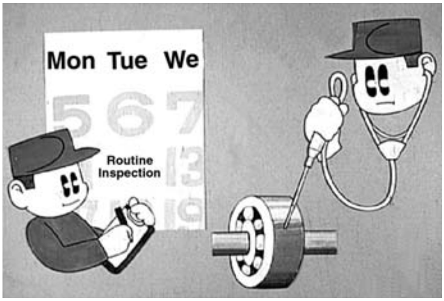
If the outer ring is interference-fit into the housing and the interference is large, depending upon the dimensions and shape of the housing, the housing can be heated to accommodate the outer ring, but cold fitting is generally used. With this method, the outer ring is shrunk using a coolant such as dry ice. With cold fitting, however, moisture in the atmosphere tends to condense on the bearing surface, thus necessitating suitable measures for preventing rust and frostbite.

16.2 Post-Installation Running Test

After mounting, the bearings must be checked to make sure they are properly installed. First, turn the shaft or housing with your hand to make sure there is no looseness, the torque isn't too great, or anything else out of the ordinary. If you don't notice anything unusual, run the equipment at low speed without a load. Gradually increase speed and load while checking rotation. If you notice any unusual noise, vibration or temperature increase, stop operation and check out the problem. If necessary, remove and inspect the bearing. You can check the sound volume and the tone of the turning bearing by placing a stethoscope on the housing (see **Table 11.2**).

If there is a lot of vibration, it is possible to infer the source of the problem by measuring amplitude and frequency. Bearing temperature rises along with rotation time, and then stabilizes after a certain period of time elapses. If temperature rises sharply and does not stabilize no matter how much time elapses, you must stop operation and investigate the cause of the problem.

Possible causes include too much lubricant, too much seal interference, insufficient clearance, and too much pressure. It is best to measure bearing temperature by touching the measurement probe to the outer ring, but temperature is sometimes measured from the housing surface, or if there is no problem with doing so, by feeling the housing with the hand.



16.3 Bearing Removal

Bearings are removed for routine inspection and parts replacement. The shaft and housing are usually always reused, and in many cases the bearing itself can be reused. It is therefore important to be careful not to damage the bearing when removing. In order to do so, a structural design that facilitates removal and the use of proper tools are required. When removing a bearing ring mounted with interference, withdrawal load must be placed on that ring only. Never attempt to remove a bearing ring via the rolling elements.

(1) Cylindrical bore bearing removal

As shown in **Figs. 16.7** and **16.8**, a press or puller are often used to remove small bearings. Design must also take removal into consideration as shown in **Figs. 16.9** - **16.11**. Removal of large interference-fit bearings used for an extended period of time require a large load. Such bearings should be designed for removal by hydraulic means such as shown in **Fig. 16.12**. Inductance heaters can be used to remove cylindrical roller bearings with separable inner and outer rings.

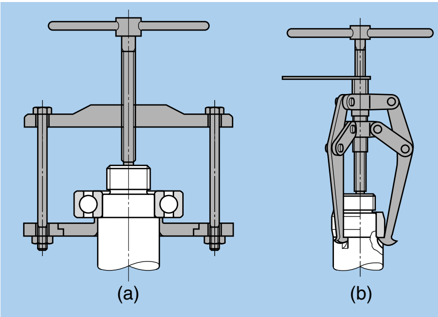


Fig. 16.7 Removal by Puller

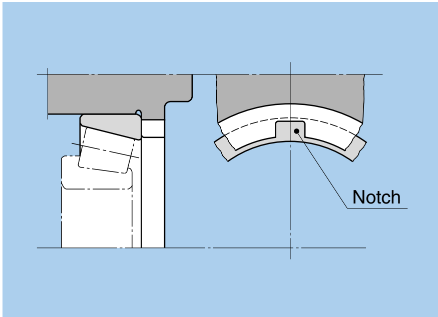

Fig. 16.10 Notch for Outer Ring Removal

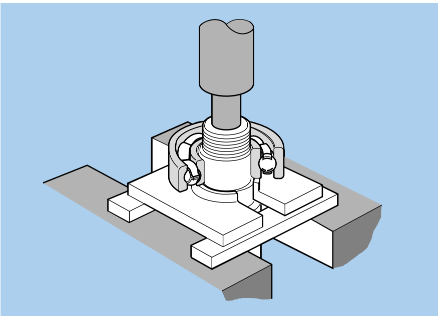

Fig. 16.8 Removal by Press

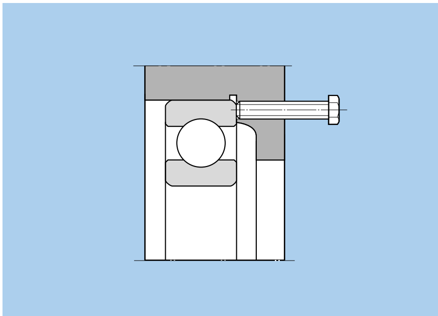

Fig. 16.11 Bolt for Outer Ring Removal

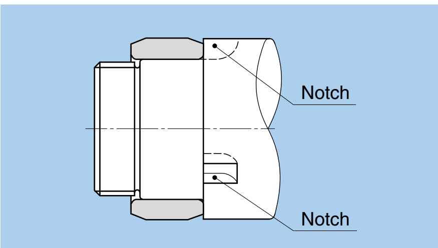

Fig. 16.9 Notch for Removal

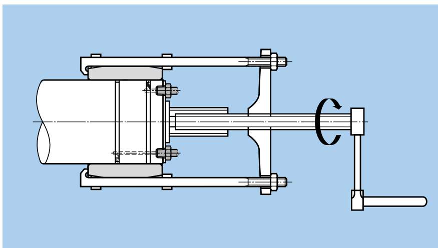

Fig. 16.12 Removal by Hydraulic Means

16

(2) Tapered bore bearing removal

Small bearings mounted using an adapter sleeve are removed by loosening the fastening nut, placing a metal block on the inner ring as shown in **Fig. 16.13**, and tapping with a hammer.

The task of removing large bearings mounted on a tapered shaft using an adapter sleeve or withdrawal sleeve is facilitated by using a hydraulic means of removal. (See **Figs. 16.14** and **16.15**)

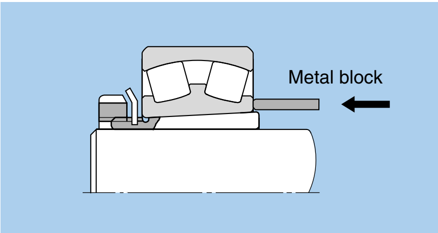

Fig. 16.13 Removal of Bearing W/Adapter Sleeve

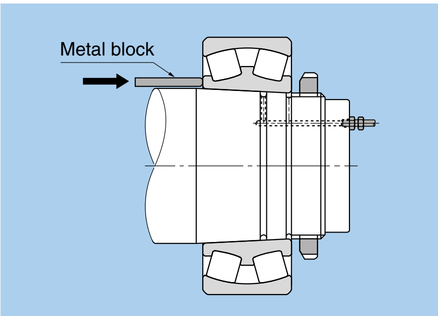

Fig. 16.14 Removal of Bearing by Hydraulic Means

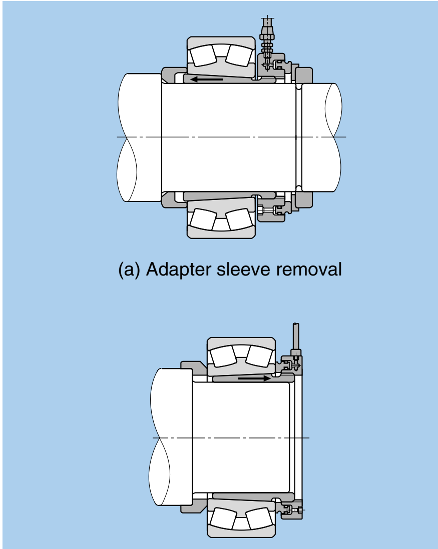

Fig. 16.15 Removal by Hydraulic Nut

16.4 Press Fit and Pullout Force

The force required to press fit or remove a bearing on/from a shaft or in/from a housing is calculated by the following equations.

For shaft and inner ring:

$$K_d = \mu \cdot P \cdot \pi \cdot d \cdot B \quad \cdots\cdots\cdots\cdots\cdots (16.1)$$

For housing and outer ring:

$$K_D = \mu \cdot P \cdot \pi \cdot D \cdot B \quad \cdots\cdots\cdots\cdots\cdots (16.2)$$

Where:

K_d : Inner ring press fit or withdrawal force N {kgf}
K_D : Outer ring press fit or withdrawal force N {kgf}
P : Fit surface pressure MPa {kgf／mm²}

Inner ring $P = \frac{E}{2} \frac{\Delta_{deff}}{d} \frac{(1-k^2)(1-k_0^2)}{1-k^2 k_0^2}$

Outer ring $P = \frac{E}{2} \frac{\Delta D_{eff}}{D} \frac{(1-h^2)(1-h_0^2)}{1-h^2 h_0^2}$

Where:

$k = \frac{d}{d_i}$ $\quad k_0 = \frac{d_0}{d}$ $\quad h = \frac{D_e}{D}$ $\quad h_0 = \frac{D}{D_0}$

d : Inner ring bore (shaft diameter) mm
d_i : Inner ring raceway diameter mm
d_0 : Hollow shaft bore ($d_0 = 0$ for solid shaft) mm
Δ_{deff} : Inner ring effective interference mm
D : Outer ring outer diameter (housing inner diameter) mm
D_e : Outer ring raceway diameter mm
D_0 : Housing outer diameter mm
ΔD_{eff} : Outer ring effective interference mm
E : Modulus of longitudinal elasticity 2.07×10^6 MPa {21 200kgf／mm²}
μ : Friction factor (see **Table 16.1**)
B : Width of inner ring or outer ring mm

Table 16.1 Friction Factor for Press Fitting and Withdrawal

Applications	μ
When inner (outer) ring is press-fitted on/into cylindrical shaft (hole)	0.12
When inner (outer) ring is withdrawn from cylindrical shaft (hole)	0.18
When inner ring is press-fitted onto tapered shaft or sleeve	0.17
When inner ring is withdrawn from tapered shaft	0.14
When sleeve is press-fitted onto shaft/bearing	0.30
When sleeve is withdrawn from shaft/bearing	0.33

16

17. Bearing damage and corrective measures

As long as they are handled properly, bearings can usually be used the entire extent of their rolling fatigue life. Premature damage is usually the result of improper bearing selection, handling, lubrication or sealing device. Because there are so many factors involved, it is almost impossible to infer the cause from the appearance of the damage. It is however important to know the type of machine used, the location and conditions of usage and construction surrounding the bearing, etc., and infer the cause from the situation when the damage occurred and the type of damage to prevent reoccurrence. Primary causes and corrective measures for bearing damage are given in **Table 17.1 (a), (b), (c), (d)** and **(e)**.

Table 17.1 (a) Bearing damage and corrective measures

Description	Causes	Corrective measures
●Flaking  Flakes form on the surfaces of the raceway and roller elements. When the flakes fall off, the surface becomes rough and uneven.	● Excessive loads, fatigue life, improper handling ● Improper mounting ● Insufficient precision of shaft or housing ● Insufficient clearance ● Contamination ● Rust ● Improper lubrications ● Softening due to abnormal temperature rise	● Select another type of bearing. ● Reconsider internal clearance. ● Improve precision of shaft or housing. ● Improve operating conditions. ● Improve method of assembly and handling. ● Check bearing periphery. ● Reconsider lubricant and lubrication method.
●Seizure  Bearing heats up, becomes discolored and eventually seizes up.	● Insufficient clearance (including clearances made smaller by local deformation) ● Insufficient lubrication, improper lubricant ● Excessive load (excessive preload) ● Roller skew ● Softening due to abnormal temperature rise	● Reconsider lubricant type and quantity. ● Reconsider internal clearance (enlarge internal clearance). ● Prevent misalignment. ● Reconsider operating conditions. ● Improve method of assembly and handling.

17

Table 17.1 (b) Bearing damage and corrective measures

Description	Causes	Corrective measures
●Cracking and notching  Localized flaking and cracking.	● Excessive shock load ● Improper handling (use of steel hammer and impact of large foreign particles) ● Surface deformation due to improper lubrication ● Excessive interference ● Large flaking ● Friction cracks ● Insufficient precision of counterpart (fillet radius too large)	● Reconsider lubricant (prevent friction cracks). ● Reconsider proper interference and material. ● Reconsider operating conditions. ● Improve method of assembly and handling.
●Cage damage  Rivets become loose or break off. Cage becomes damaged.	● Excessive moment load ● High-speed rotation or excessive rotation fluctuation ● Improper lubrication ● Impact of foreign matter ● Excessive vibration ● Improper mounting (misalignment)	● Reconsider lubricant and lubrication method. ● Select a different type of cage. ● Investigate rigidity of shaft and housing. ● Reconsider operating conditions. ● Improve method of assembly and handling.
●Meandering wear patterns  Meandering or irregular wear of raceway surface by rolling elements	● Insufficient precision of shaft or housing. ● Improper mounting ● Insufficient rigidity of shaft and housing ● Shaft sling due to excessive internal clearance	● Re-check internal clearance. ● Reconsider machining precision of shaft or housing. ● Reconsider rigidity of shaft and housing.

Table 17.1(c) Bearing damage and corrective measures

Description	Causes	Corrective measures
●Smearing and scuffing     Surface becomes rough with small deposits. "Scuffing" generally refers to roughness of the bearing ring ribs and roller end faces.	● Improper lubrication ● Invasion of foreign matter ● Roller skew due to bearing misalignment ● No oil on rib surface due to excessive axial load ● Excessive surface roughness ● Excessive sliding of rolling elements	● Reconsider lubricant and lubrication method. ● Improve sealing performance. ● Reconsider preload. ● Reconsider operating conditions. ● Improve method of assembly and handling.
●Rust and corrosion     Surface becomes partially or fully rusted. Rust may also develop on rolling element pitch lines.	● Improper storage ● Improper packaging ● Insufficient rust preventative ● Invasion of moisture, acid, etc. ● Handling with bare hands	● Take measure to prevent rusting while in storage. ● Inspect lubricant on regular basis. ● Improve sealing performance. ● Improve method of assembly and handling.
●Fretting   There are two types of fretting: the type where rust-colored wear powder forms on fitting surfaces, and the type where brinneling indentation forms on the raceway along the pitch of the rolling elements.	● Insufficient interference ● Small bearing oscillation angle ● Insufficient lubrication (unlubricated) ● Fluctuating load ● Vibration during transport or when not operating	● Select a different type of bearing. ● Reconsider lubricant and lubrication method. ● Reconsider interference and apply lubricant to fitting surface. ● Package inner and outer rings separately for transport.

Description	Causes	Corrective measures
●Wear  The surface becomes worn, resulting in dimension change. Wear is often accompanied by roughness and damage.	● Foreign matter in the lubricant ● Insufficient lubrication ● Roller skew	● Reconsider lubricant and lubrication method. ● Improve sealing performance. ● Prevent misalignment.
●Electrolytic corrosion  Pits form on raceway and develop into ripples.	● Electric current flowing through raceway	● Create a bypass for current. ● Insulate the bearing.
●Dents and scratches  Impact of solid foreign matter. Scoring during assembly, gouges in surface due to impact.	● Solid foreign matter ● Dents caused by flakes ● Impact or dropping due to improper handling ● Misalignment when assembling	● Improve method of assembly and handling. ● Improve sealing performance (to prevent foreign matter from getting inside). ● Check bearing periphery (when caused by metal shavings).

Description	Causes	Corrective measures
●Creep  Surface becomes mirror finished due to slipping of the inner and outer surfaces. Sometimes accompanied by discoloration or scuffing.	● Insufficient interference of fitted parts ● Insufficient sleeve tightening ● Abnormal temperature rise ● Excessive load	● Reconsider interference. ● Reconsider operating conditions. ● Reconsider machining precision of shaft and housing.
●Surface matting  Surface luster disappears, and surface becomes matted and rough. Surface becomes covered with tiny dents.	● Foreign matter ● Improper lubrication	● Reconsider lubricant and lubrication method. ● Improve sealing devices ● Clean lubricating oil (with filter)
●Peeling  Patches of minute peeling (approx. 10 μm). Accompanied by innumerable cracks that have not yet peeled. (Tends to form on roller bearings.)	● Foreign matter ● Improper lubrication	● Reconsider lubricant and lubrication method. ● Improve sealing performance (prevent foreign matter from getting in). ● Perform warm-up operation prior to work.

One-Point Advice

Bearing Tips

●Transition of NTN Technology (Introduction of "Technical Review")

NTN technology has developed along with advancements in various industries based on rolling bearings. There is practically no industry that can exist without the use of bearings, beginning with the steel industry in the postwar reconstruction period, and including railway cars, automobiles, aircraft, high-speed communications and environment-related industries. Some of these are covered in **NTN** TECHNICAL REVIEW (formerly "Bearing Engineer").

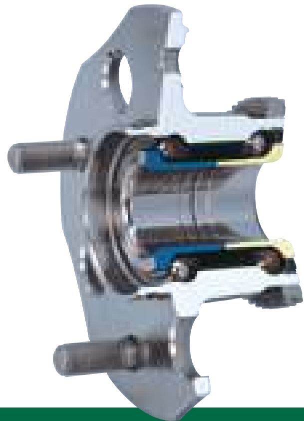
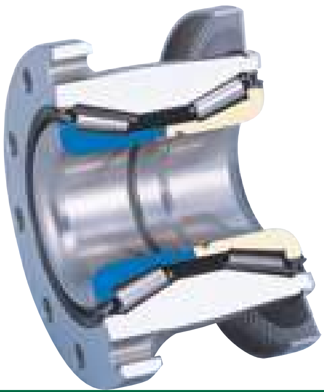
2 Bearing number

GEN 1 ball type

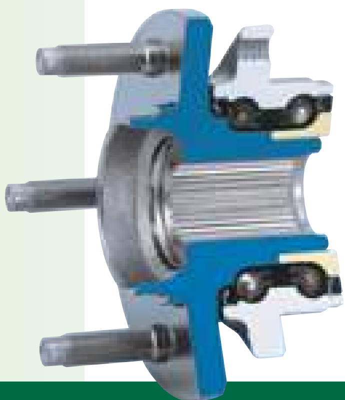
GEN 1 roller type

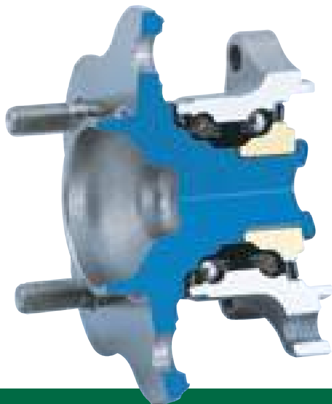




GEN 2 ball type

GEN 2 roller type





GEN 3 ball type (driven wheel)

GEN 3 ball type (non driven wheel)

Bearing type	Code name	Bearing number	Configuration
GEN 1 Ball type	AU	AU 08 04—1 LL ／L260 L260: Grease code LL: Seal code 1: Sequential number 08: Inner diameter No. AU: Type code	Consists of inner ring, outer ring, balls, cage and seal.
GEN 1 Roller type	TU	TU 08 11—1 LXL ／L244 L244: Grease code LXL: Seal code 11—1: Sequential number 08: Inner diameter No. TU: Type code	Consists of inner ring, outer ring, rollers, cage and seal.
GEN 2 Ball type	HUB	HUB 227—1 227—1: Sequential number HUB: Type code	Consists of inner ring, outer ring, balls, cage and seal. Outer ring rotating type: Brake disc and wheel mounted on hub/outer ring unit. Inner ring rotating type: Outer ring with flange fastened to vehicle body.
GEN 2 Roller type	HUR	HUR 040—2 040—2: Sequential number HUR: Type code	Consists of inner ring, outer ring, rollers, cage and seal. Outer ring rotating type: Brake disc and wheel mounted on hub/outer ring unit. Inner ring rotating type: Outer ring with flange fastened to vehicle body.
GEN 3 Ball type	HUB___T	HUB 005T—1 005T—1: Sequential number HUB: Type code	Consists of inner ring, outer ring, balls, cage and seal. Outer ring rotating type: Brake disc and wheel mounted on hub/outer ring unit, outer ring with flange fastened to vehicle body. Inner ring rotating type: Outer ring with flange fastened to vehicle body, Brake disc and wheel mounted on hub.

3 Hub bearing selection

3.1 Selection overview

Hub bearings are very important part in terms of vehicle safety. Selecting the type of bearing most suited to the vehicle ensures safety and is very important for exhibiting the required performance. To select the best bearing, one must consider and evaluate the bearings from a variety of angles. The procedure for selecting hub bearings is provided in the form of a flowchart.

Hub bearing selection flowchart

Order	Check, study and evaluation items
Usage conditions check ↓	● Vehicle model ● Front/rear ● Vehicle specifications ● Custom specifications ● Configuration of area surrounding bearing ● Driven / non driven wheel ● Traveling conditions ● Evaluation test items / determination standards
Bearing type selection ↓	● Allowable space for bearing ● Rigidity ● Whether or not equipped with ABS sensor ● Cost ● Inner/outer ring rotation ● Whether or not equipped with seal ● Ease of assembly, serviceability
Bearing type study ↓	● Life calculation ● Shoulder protrusion (ball type) ● Flange PV value (roller type) ● Seal type ● Tone wheel ● Magnetic encoder ● Allowable stress ● Rigidity/strength ● Bearing materials ● Grease ● ABS sensor
Initial axial clearance study ↓	● Axle/housing material and shape ● Fitting ● Nut fastening torque / axial force ● Axial clearance reduction amount calculation (preload setting)
Sample fabrication ↓	● Quality check
Evaluation by various tests	● Fitting test ・Axial clearance reduction amount measurement (verification of set preload) ● Bearing bench test ・Life evaluation test / seizure resistance evaluation test ・Seal performance evaluation test ● Actual vehicle test

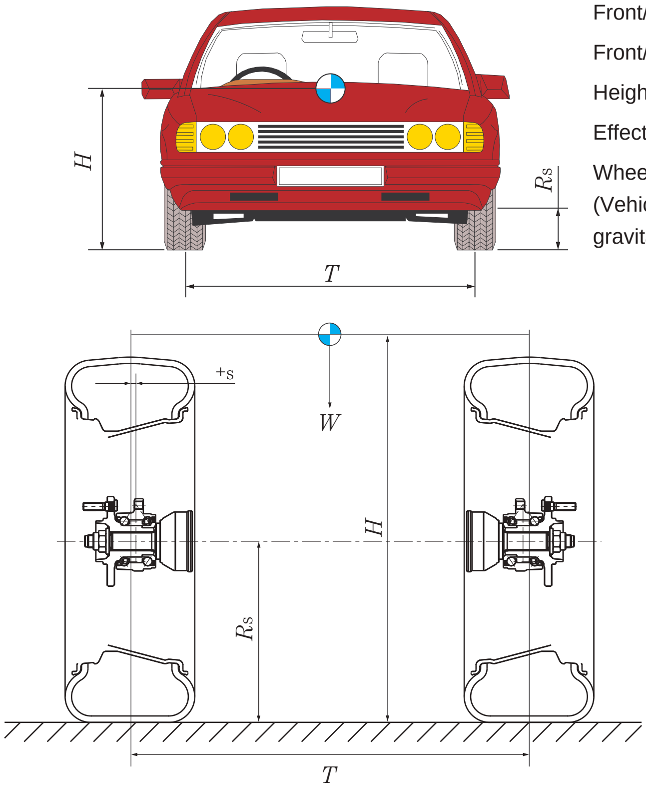
3.3 Life calculation

Life of hub bearings is calculated by inputting reaction force (radial load and axial load) on the wheel given as set traveling conditions as load. Each bearing is a "unit bearing" consisting of two rows of bearings. Life of the bearings is calculated separately for the each of the bearings. Bearing life is calculated for the outer and inner bearings. The shorter of the calculated values is considered the calculated life of hub bearings.

1) Vehicle specifications



Front/rear wheel axle static load ···W (N)
Front/rear wheel tread ··················T (mm)
Height of gravitational center ·········H (mm)
Effective radius of tires ···············Rs (mm)
Wheel offset ·································S (mm)
(Vehicle outside positive relative to gravitational center of bearing)

2) Calculation of road reaction force

First, we calculate road reaction force applied to the wheel by the road. Road reaction force in the axial and radial directions is calculated by the following formula.

$$W_r = f_w\,(W/2 + G \cdot W \cdot H/T)$$
$$W_t = G \cdot W_r$$

W_r : Road reaction force in the radial direction (N)
W_t : Road reaction force in the axial direction
f_w : Load coefficient
G : Turning acceleration (positive in case of turning outer wheel, negative in case of turning inner wheel)

3) Calculation of bearing load

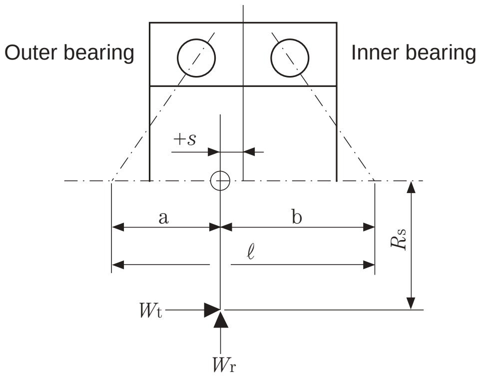
Next, we calculate bearing load (radial/axial load) applied by road reaction force on the wheel.

(1) Radial load

Radial load applied to outer/inner bearing is determined by the following formula:

$$F_{ro} = | b/\ell \times W_r - R_s/\ell \times W_t |$$
$$F_{ri} = | a/\ell \times W_r + R_s/\ell \times W_t |$$

F_{ro} : Outer bearing radial load (N)
F_{ri} : Inner bearing radial load (N)
ℓ : Distance between pressure cone apexes (mm)
a : Distance from pressure cone apex of outer bearing to wheel center (mm)
b : Distance from pressure cone apex of inner bearing to wheel center (mm)



(2) Axial load

If an axial load is applied to the hub bearing, induced thrust is produced by the radial load. Induced thrust load when there is no clearance (no preload) is determined by the following formula. Induced thrust can be calculated by altering the clearance (preload), but such is extremely complicated. You may leave the calculation up to **NTN** in this case.

$F_{ro}/(2Y)$: Outer bearing induced thrust load (N)
$F_{ri}/(2Y)$: Inner bearing induced thrust load (N)
Y : Axial load coefficient
(For the Y coefficient, use the value of $F_a/F_r > e$ of **tables 1** and **2**.)

Next, we compare large and small values of induced thrust load produced for the inner and outer bearings. In this case, you must take note of the direction of the induced thrust load and direction of outside force axial load.

Example: Axial load in the case of turning outer wheel (and $F_{ri}/(2Y) + W_t > F_{ro}/(2Y)$) is as follows:
Outer bearing axial load: $F_{ao} = F_{ri}/(2Y) + W_t$
Inner bearing axial load: F_{ai} = O

3) Equivalent radial load

Equivalent radial load if the inner and outer bearings is determined by the following formula:

$$P_r = XF_r + YF_a$$

At this time, X and Y are called the radial load coefficient and axial load coefficient respectively, and use a different value for each type of bearing. The X and Y coefficients are given in **tables 1** and **2**.

Table 1 X and Y coefficients of radial ball type

Contact angle α	X		Y		e
	$F_a/F_r \leqq e$	$F_a/F_r > e$	$F_a/F_r \leqq e$	$F_a/F_r > e$	
35	1	0.37	0	0.66	0.95
40	1	0.35	0	0.57	1.14

X=1 and Y=0 are used in the case of $F_a/F_r \leqq e$.

Table 2 X and Y coefficients of radial roller type

Contact angle α	X		Y		e
	$F_a/F_r \leqq e$	$F_a/F_r > e$	$F_a/F_r \leqq e$	$F_a/F_r > e$	
$\alpha \neq 0$	1	0.4	0	0.4cotα	1.5tanα

4) Bearing life calculation

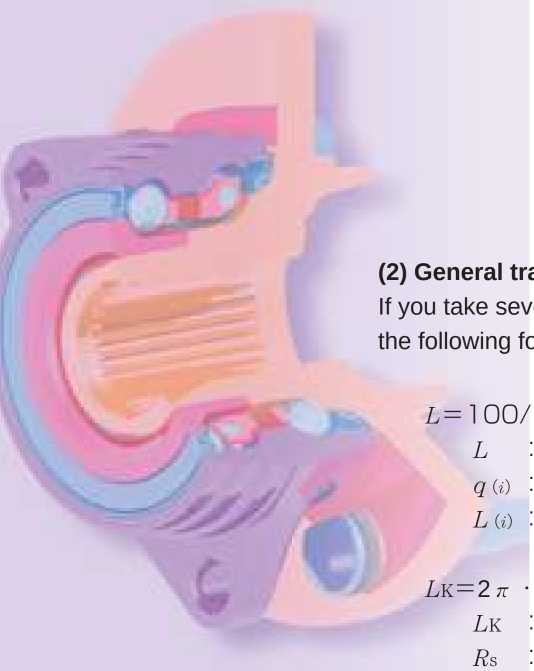
(1) Rated life

Rated bearing life is determined by the following equation.

$$L_{10} = (C_r/P_r)^p$$

L_{10} : Rated bearing life ($\times 10^6$ rotations)
p : Constant (3 in case of ball type, 10/3 in case of roller type)
C_r : Basic load rating (N) of radial bearing (single row)
P_r : Equivalent radial load (N)

Hub bearing selection



(2) General travel distance life

If you take several travel conditions into consideration, you can determine general travel distance life by the following formula integrating the respective calculated lives.

$$L=100/\Sigma\ [q_{(i)}/L_{(i)}]$$

L : General life (×10^6 rotations)

$q_{(i)}$: Frequency of each traveling condition (%)

$L_{(i)}$: Calculated life of each traveling condition (×10^6 rotations)

$$L_K=2\pi\cdot R_s\cdot L/10^6$$

L_K : General travel distance life (km)

R_s : Effective tire radius

An example of life calculation results is provided in **Fig. 1** for your reference.

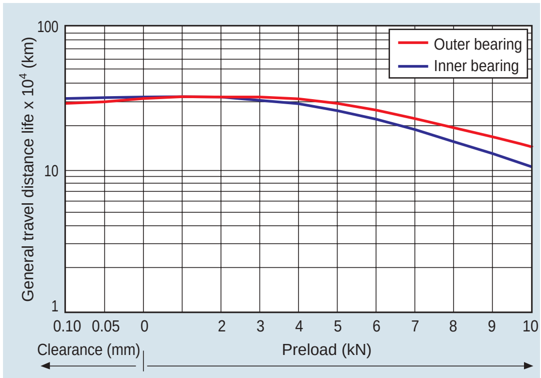


Fig. 1 Example of life calculation results

3.4 Allowable stress and shoulder protrusion

1) Allowable stress

When a load is placed on a bearing, contact stress at the center of the rolling elements and raceway where the maximum stress is received should be no greater than the following values:

Ball type : 4,200 MPa

Roller type: 4,000 MPa

2) Shoulder protrusion

The contact surface of the rolling elements and raceway is generally elliptical in shape. If the radius of the major axis of the contact ellipse protrudes from the shoulder of the inner or outer ring, concentrated stress is produced at the shoulder. Because it could result in early damage, take measure to prevent the contact ellipse from protruding from the shoulders.

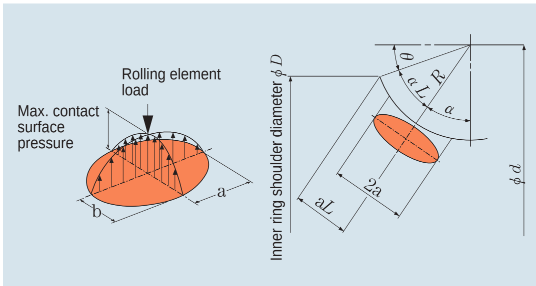

Fig. 2

3.5 Rigidity

Moment load is placed on hub bearings when the vehicle turns, which produces an inclination in the tire mounting surface. Variation in the angle of incline is called "rigidity" of the hub bearing.

Rigidity of the hub bearing is determined by the amount of elastic distortion of the rolling elements, hub or hub with outer ring. The amount of distortion is calculated by structural analysis (FEM).

Elastic distortion of the rolling elements is affected by internal clearance of the hub bearing. A comparison of angle of housing incline for clearance and preload (negative clearance) is given in **Fig. 3**.

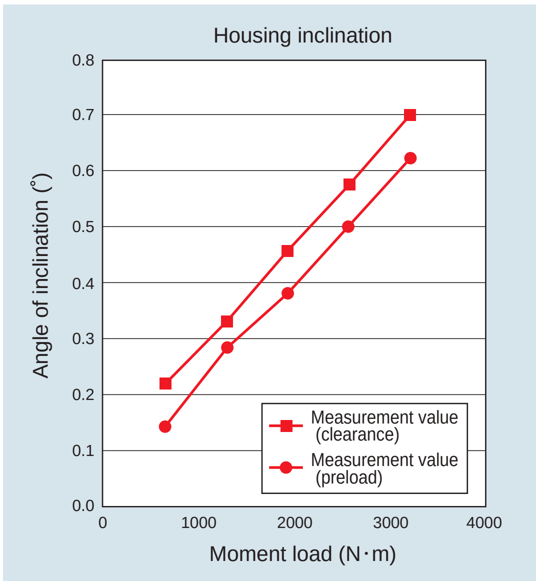

Fig. 3: Housing incline rigidity measurement example

3.6 Strength

When inclination rigidity and strength of a hub bearing is analyzed by FEM, the optimal shape taking weight reduction into account must be decided.
Fig. 4 gives an example of housing strength analysis and **Fig. 5** gives an example of a study of weight reduction.

3.7 Fitting and preload

Bearings are generally provided with a slight internal clearance during operation. Hub bearings use the preload method whereby a negative axial clearance is provided after assembly. The effects of preload are as follows:

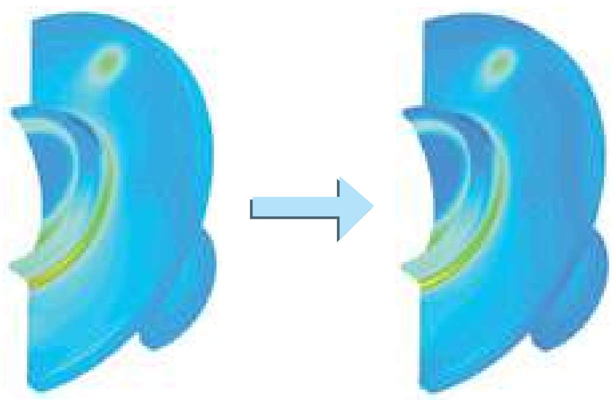
(1) Internal clearance does not tend to be produced by elastic distortion when a load is placed on the bearing and rigidity is high.
(2) Axle run-out is suppressed and rotation precision is enhanced.
(3) Prevents fretting from being produced on the raceway by external vibration.

If excessive preload is applied, however, it can invite reduction of life, abnormal heating, or increase in rotational torque. With hub bearings, therefore, fitting and initial axial clearance are decided to produce suitable preload.

Axial clearance of hub bearings is reduced by fitting with other parts and nut fastening. This reduction in clearance is taken into account when initial axial clearance is established. The amount of reduction is confirmed by fitting test using the actual parts. If fastening due to fitting of the bearing inner ring is too tight, undesired conditions such as galling of the press fitting surface, distortion and inner ring cracking may be produced. Fitting is decided by calculating maximum stress on the inner ring when fitting.
For fitting and stress, you should consult with **NTN**.
Recommended fitting for each type of bearing is given in **Table 3**.

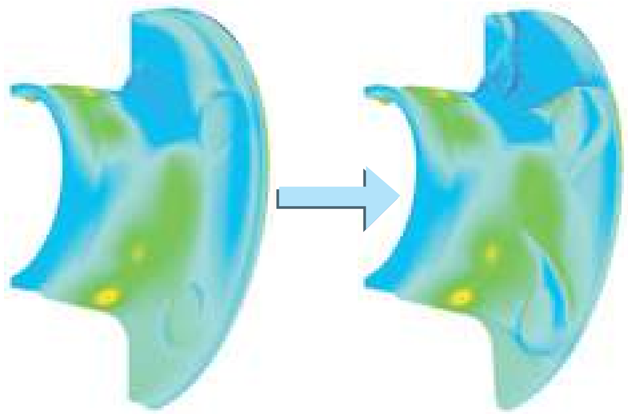
Table 3 Recommended fitting

Bearing type		Axle	Housing
GEN 1	Inner ring rotation	m6	R7
	Outer ring rotation	m6	R7
GEN 2	Inner ring rotation	m6	—
	Outer ring rotation	Loose	—



The corner R dimension is decided by studying housing corner R stress.

Fig. 4 Example of strength analysis of housing



Weight is reduced without excessively reducing strength by changing type of flange for hub with outer ring.

Small Large

Fig. 5 Example of weight reduction

4. Hub bearing materials

4.1 Raceway and rolling element materials

Innovations in steel manufacturing technologies such as vacuum gas removal, out-of-furnace smelting and continuous casting have notably reduced harmful non-metallic inclusion, thus realizing longer bearing life. **NTN** selects quality materials that best suit each type of bearing.

(1) NKJ65M

Based on carbon steel, NKJ65M was developed as a substitute for SUJ2. NKJ65M is high quality clean carbon steel that offers lower cost and better rolling fatigue life.
NKJ65M is used for the inner and outer rings of the GEN 1 and inner rings of the GEN 2 and GEN 3 ball types.

(2) SUJ2 (equivalent of SAE52100)

The most commonly used material, SUJ2 is a quality material having minimal non-metallic inclusion.
SUJ2 is used for balls, the inner and outer rings of the GEN 1 and balls and inner rings of the GEN 2 and GEN 3 ball types.

(3) S53C (equivalent of SAE1053)

Raceways are made of induction hardened S53C, a highly forgeable carbon steel. S53C offers superior characteristics such as rotational bending fatigue strength and impact resistance as well as long rolling fatigue life.
S53C is used for the hub, outer ring of GEN 2 and GEN 3 ball types and outer ring of GEN 2 roller type.

(4) ET material (equivalent of SCr4435)

Hardened from the surface to a suitable depth, ET material forms a comparatively soft core. Offering a combination of hardness and toughness, ET material is long-life case hardened steel with superior impact resistance.
ET material is used for the rollers, inner and outer rings of the GEN 1 roller type, and the rollers and inner ring of the GEN 2 roller type.

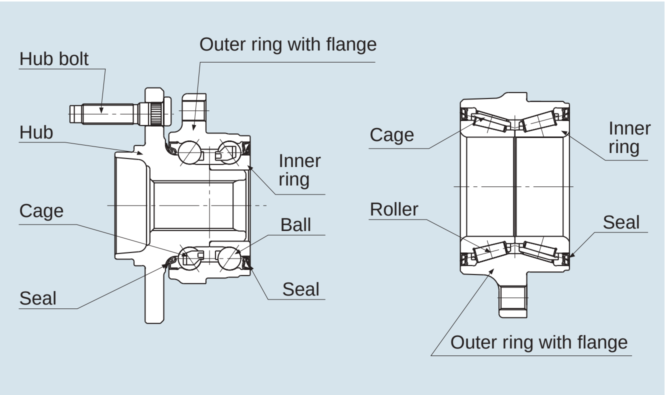


Fig. 6 Material part names

(5) ETA material

ETA material is a long-life case hardened steel that is specially heat-treated (carbonitriding) to enhance toughness of the surface layer structure. It is particularly effective for suppressing cracking caused by contaminated lubrication.
ETA material is used for the rollers, inner and outer rings of the GEN 1 roller type, and the inner ring of the GEN 2 roller type.

4.2 Cage material

Cages are made of polyamide resin reinforced with fiberglass, except the roller type for use in high temperature environments, which is made of cold rolled steel.

5. Lubrication

The objective of lubricating bearings is to form a film of oil on rolling or sliding surfaces to prevent the metals from making direct contact with each other. Lubrication has the following effects:

(1) Reduces friction and wear.
(2) Extends bearing life.
(3) Prevents rusting.
(4) Prevents penetration of foreign matter.

Fretting wear particularly tends to occur on the raceway of hub bearings during transport of finished automobiles. Fretting resistance must therefore be taken into account for hub bearings.
Grease is used for hub bearings because it is economical, easy to use, and it facilitates design of sealed equipment.
Table 4 gives characteristics of greases currently used for hub bearings.

Table 4 Characteristics of grease

Characteristics	Resists fretting, enhances rust prevention performance.	Resists fretting, extends life at high temperatures.
Maker	Nisseki Mitsubishi	Kyodo Yushi
Name	PYRONOC Universal N6C	Raremax 9B367
Thickener	Urea	Urea
Base oil	Mineral oil	Mineral oil and synthetic oil
Working temperature (˚)	-30 to 150	-30 to 150
Color	Cream	Yellow
Remarks	Recommended grease for passenger vehicles	HUR/TU recommended grease for trucks and passenger vehicles.

6. Seals

Hub bearing seals prevent water ingress and have low torque. The shape and characteristics of currently used seals are given in **Table 5**.

7. Orbital forming

Nuts were used to fasten the inner ring of the GEN 3 ball type, but we have recently switched to forming the end of the hub with cold plastic working (orbital forming) to fasten the inner ring. This method is more reliable than fastening with nuts. It also weighs less, costs less, and is more compact.
Fig. 7 shows the orbital forming method and **Fig. 8** gives examples of the forming structures for the driven and non driven wheels.

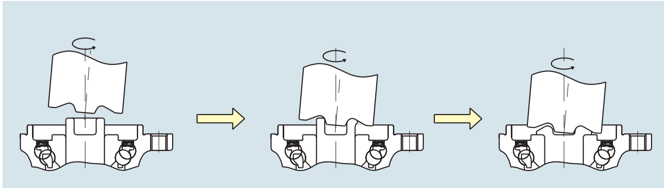

Fig. 7: Orbital forming method

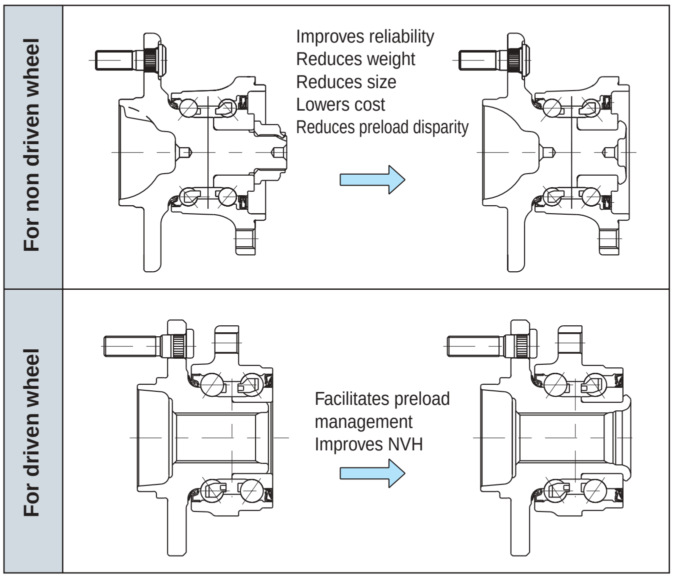

Fig. 8: Examples of fastening configuration for driven/non driven wheel inner ring forming

Hub bearing for active ABS sensor

8. Hub bearing for active ABS sensor

8.1 Magnetic encoder for active sensor

In the past electromagnetic sensors and magnetic tone wheels (passive type) have been used to detect wheel rotational speed for antilock brake systems (ABS). In recent years, however, makers have begun to use sensors equipped with a semiconductor element that can detect extremely low speed ranges (active type).
Some active type semiconductor sensors are equipped with a built-in bias magnet and some are not. The former uses a conventional tone wheel, and the latter requires a multipolar magnetized encoder.

(1) Types

There are two types of magnetized encoder: axial and radial type according to sensing direction (see **Fig. 9**).

(2) Features

Conventional sintered tone wheels are designed with a large diameter. Magnetic encoders enable smaller outer diameter and more compact size. **Fig. 10** shows an example of more compact construction.

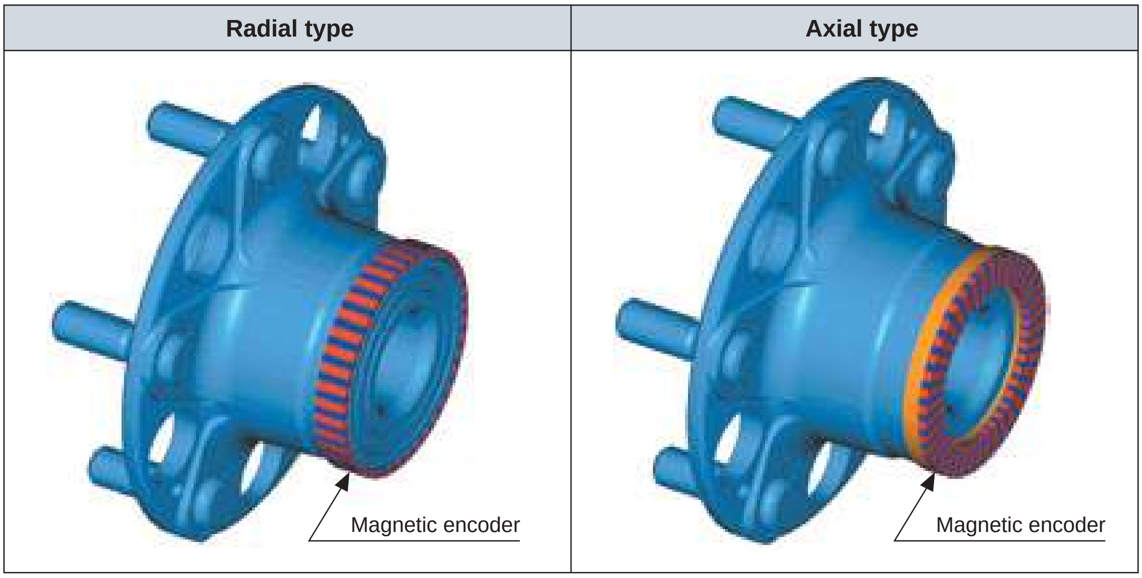

Fig. 9 Configuration of radial and axial type encoders

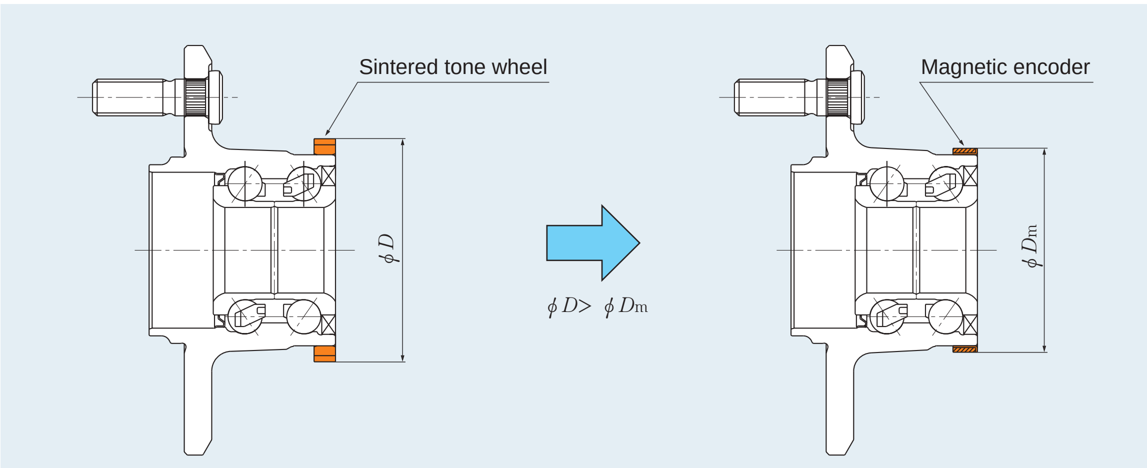

Fig. 10 More compact construction (comparison with GEN 2 ball type for non driven wheel)

8.2 Hub bearing with integrated ABS sensor

(1) Configuration

With GEN 2 and GEN 3 hub bearings, the ABS sensor and magnetic encoder can be unified with the axle. The ones for the driven wheel are provided with the ABS sensor and magnetic encoder between two rows of raceway surfaces, and the ones for the non driven wheel are provided with the ABS sensor and magnetic encoder on the inner side, and are unified with the bearing as a single unit.

Fig. 11 shows examples of the configuration of the GEN 3 ball type with integrated ABS sensor.

(2) Features

1. Less weight, more compact: Unifying the magnetic encoder and seal as a single unit enables more compact configuration in the axial direction.
2. Enhanced reliability relative to the outside environment: Housing the ABS sensor and magnetic encoder within the bearing prevents damage from small stones and rust due to dirty water or saltwater and enhances reliability.
3. Doesn't require air gap adjustment: Housing the ABS sensor and magnetic encoder within the bearing eliminates the need to adjust the air gap (distance between ABS sensor and magnetic encoder) when mounting the bearing.

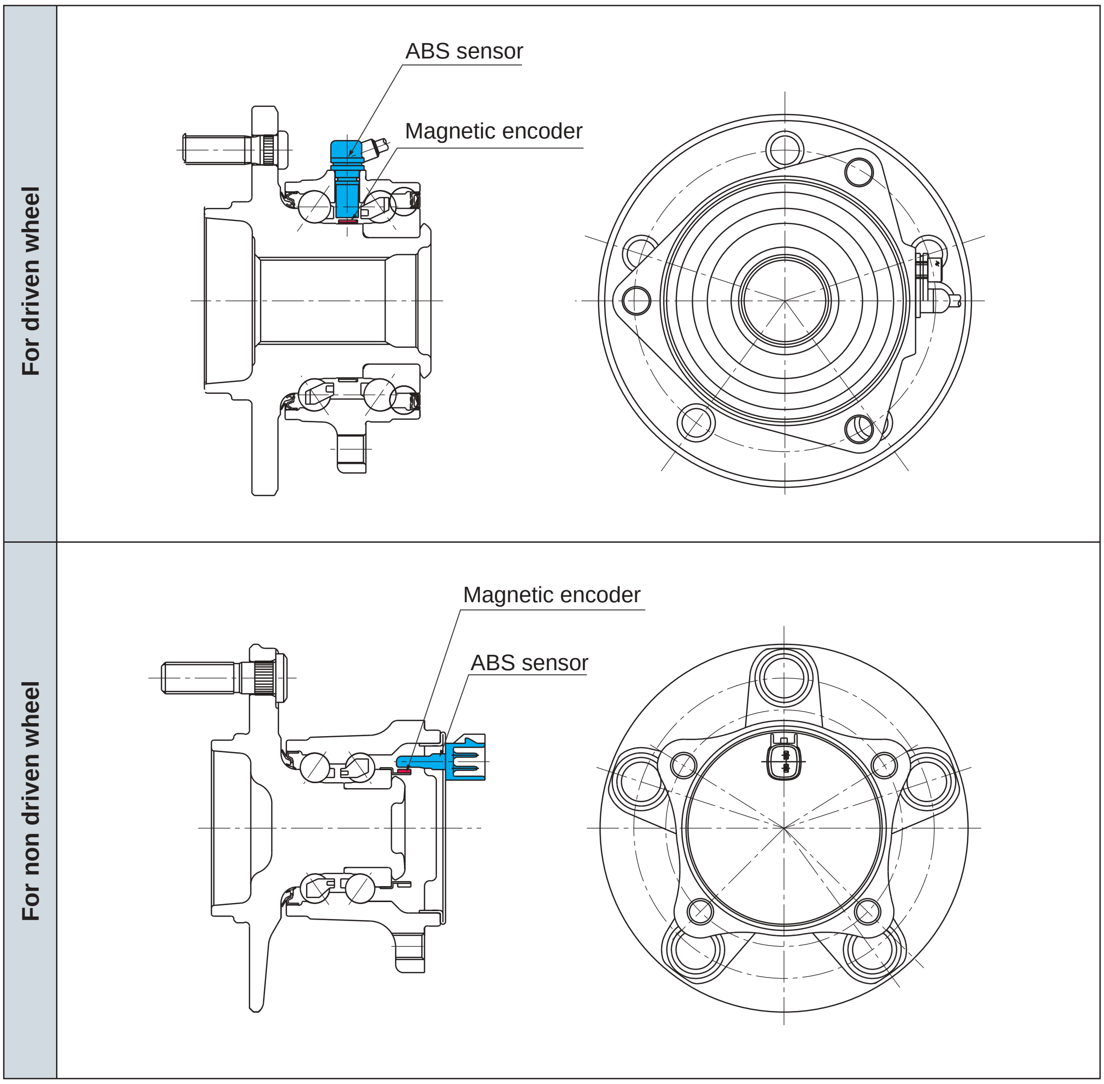

Fig. 11 Example configuration of GEN 3 ball type with integrated ABS sensor

Spherical Roller Bearings ULTAGE Series

[Type EA, Type EM]

CAT.No.3033-5/E

CAT.No.3033-5/E 22.05.005 DS/DS

Up to
3.7 times
longer
service life

【Type EA· Type EM】

ULTAGE™

Up to
20 % higher
allowable
speed

Longer service life and higher rotational speed improve ease-of-use while contributing to more eco-friendly operation.

ULTAGE Series spherical roller bearings are products developed to provide longer service life, higher rotational speed, and improved ease-of-use required for any industrial machinery.

Longer Service Life

- Larger rollers provide the industry's highest load capacity.
- Extended maintenance intervals
- Lighter and more compact design
- Withstands operating temperatures up to 200℃.

Higher Rotational Speed

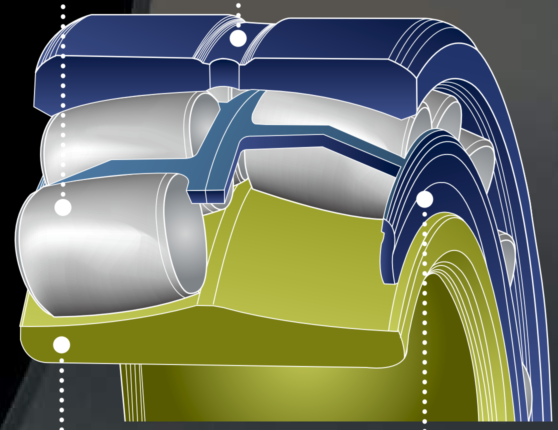
- The industry's highest allowable rotational speed
- Type EA has a simple window-type configuration employs a pressed steel cage.

Improved Ease-of-Use

- Unique structure readily accepts lubricant.
- Improved application of grease

Rollers
- Larger rollers
- Maximum number of rollers

Outer ring
- With oil inlets and oil groove
- Optimal curvature



【Type EA】

Inner ring
- No rib
- Optimal curvature

Cage
- Window-type pressed steel cage
- Cage end faces function as guides.

INDEX

ULTAGE "ULTAGE" (a name created from the combination of "ultimate," signifying refinement, and "stage," signifying NTN's intention that this series of products be employed in diverse applications) is the general name for NTN's new generation of bearings that are noted for their industry-leading performance.

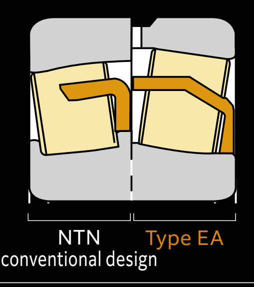
ULTAGE™ The ULTAGE Advantage【Type EA】

1 The industry's highest load capacity

These bearings have a significantly increased roller diameter and incorporate the maximum number of rollers, thus achieving both a high load capacity and a longer service life. Maintenance intervals can also be extended.

① Basic dynamic load rating: up to 50 % greater than the NTN conventional design
② Basic static load rating: up to 35 % greater than the NTN conventional design
③ Service life: up to 3.7 times longer than the NTN conventional design

Figure 1



2 The industry's highest allowable speed

The new pressed steel cage results in allowable rotational speed up to 20 % greater than NTN's conventional design.

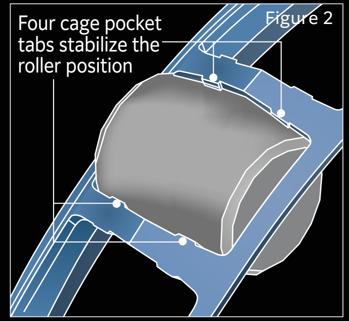


Figure 2

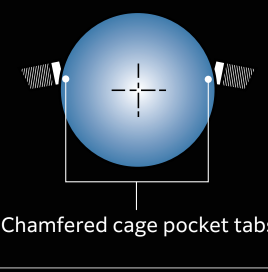
3 Pressed steel cage provided as standard.

The window-type pressed steel cage provides higher rigidity. Each roller pocket is provided with four tabs.

① The guide system employs a back-to-back cage system.
② Four tabs in each cage pocket stabilize the roller position.
③ The innovative cage pocket shape ensures a stable supply of lubricating oil or grease into the bearing.
④ A special surface treatment enhances wear resistance.

Figure 3



4 Compact, lightweight design

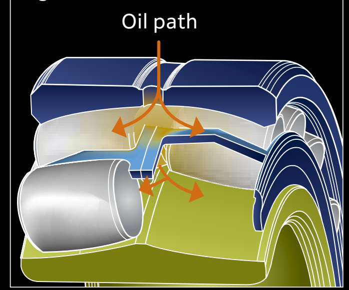
The increased load capacity contributes to a lighter and more compact design.

Benchmarks

Model No.	Load rating (kN)		Boundary dimensions (mm)	Bearing volume (cm³)	Mass (kg)
	C_r	C_{0r}			
22220B	350	415	ϕ100×ϕ180×46	810	4.95
22218EA	384	398	ϕ90×ϕ160×40	550	3.34

Results in approximately a 30 % reduction in volume ratio and mass ratio

Figure 4



5 Improved ease-of-use

Adoption of a simple window-type pressed steel cage improves ease of assembly/disassembly and grease application.

① Improved application of grease to the roller surface
② Improved roller retention contributes to easier assembly/disassembly

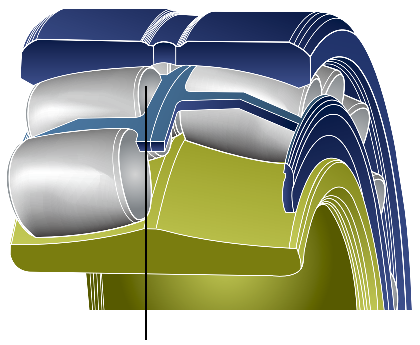
【Bearing Number】

222 20 EA K D1 C3

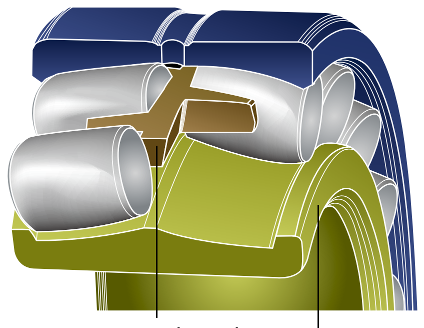
- **222** — Dimension series code
- **20** — Bore diameter code
- **EA** — Type code
  EA: Window-type pressed steel cage
  EM: One-piece machined high-tension brass cage
- **K** — Raceway configuration code
  No code: Cylindrical bore
  K: Tapered bore
- **D1** — Oil inlet/oil groove code
  D1: With oil inlet/oil groove
  W33: With oil inlet/oil groove (Made in Europe)
- **C3** — Internal clearance code
  No code: Normal clearance
  C3: C3 clearance

For applications that expose bearings to severe vibration and impact, we recommend Type EM bearings, which incorporate a high-tension brass cage machined from a single piece. (Type EM differs from Type EA in the shape of the inner ring.)

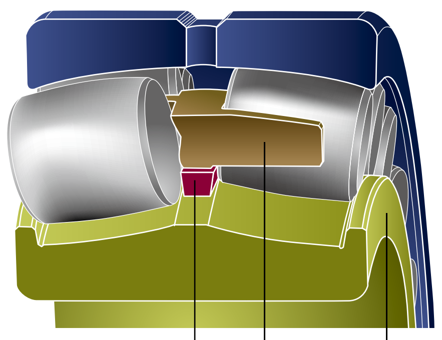
Type EA



Type EM



Type EM (Large size)



【Allowable Misalignment】

- Normal or heavy load ……… 1/115
- Light load ……………………… 1/30

*If the installed misalignment is greater than recommended, there is a risk of roller/cage protrusion and impact to surrounding components.

1 Bearing Tolerances

1.1 Dimensional accuracy and running accuracy

(1) Inner ring

unit : μm

Nominal bore diameter d mm		Dimensional tolerance of mean bore diameter in single plane Δ_{dmp} Class 0		Radial runout K_{ia} Class 0	Width deviation Δ_{Bs} Class 0		Width variation V_{Bs} Class 0
Over	Including	High	Low	Max	High	Low	Max
-	30	0	-10	13	0	-120	20
30	50	0	-12	15	0	-120	20
50	80	0	-15	20	0	-150	25
80	120	0	-20	25	0	-200	25
120	150	0	-25	30	0	-250	30
150	180	0	-25	30	0	-250	30
180	250	0	-30	40	0	-300	30
250	315	0	-35	50	0	-350	35
315	400	0	-40	60	0	-400	40
400	500	0	-45	65	0	-450	50

(2) Outer ring

unit : μm

Nominal outside diameter D mm		Dimensional tolerance of mean outside diameter in single plane Δ_{Dmp} Class 0		Radial runout K_{ea} Class 0	Width deviation Δ_{Cs} Class 0		Width variation V_{Cs} Class 0
Over	Including	High	Low	Max	High	Low	Max
50	80	0	-13	25	Same as Δ_{Bs} and V_{Bs} of bearings of same nominal bore diameterd.		
80	120	0	-15	35			
120	150	0	-18	40			
150	180	0	-25	45			
180	250	0	-30	50			
250	315	0	-35	60			
315	400	0	-40	70			
400	500	0	-45	80			
500	630	0	-50	100			

1.2 Tolerance of tapered bore

(1) Taper ratio 1:12 (Class 0)

unit : μm

Nominal bore diameter d mm		Dimensional tolerance of mean bore diameter in single plane Δ_{dmp}		Δ_{d1mp} - Δ_{dmp}		Bore diameter variation V_{dsp}
Over	Including	High	Low	High	Low	Max
-	30	+33	0	+21	0	13
30	50	+39	0	+25	0	16
50	80	+46	0	+30	0	19
80	120	+54	0	+35	0	22
120	180	+63	0	+40	0	40
180	250	+72	0	+46	0	46

Note: The nut rotation angle may only be applied when a nut having the same inner diameter code as the bearing is used.

6 Bearing Fits

(1) Tolerance class of normally used shaft

Conditions		Shaft diameter (mm) Over	Shaft diameter (mm) Including	Tolerance zone of shaft	Remarks
Cylindrical bore bearing (class 0)					
Rotating inner ring load or indefinite-direction load	Light load[1)] or normal load[1)] or varying load	18	25	k5	
		25	40	m5	
		40	60	n5	
		60	100	n6	
		100	200	p6	
		200	500	r6	
	Heavy load[1)] or impact load	50	70	n5	Use a bearing with an internal clearance greater than the CN clearance.
		70	140	p6	
		140	200[2)]	r6	
Static inner ring load	Inner ring should slide smoothly on shaft.	All shaft diameters		g6	For larger bearings, tolerance zone f6 may be applied to ensure the bearing slides smoothly on the shaft.
	Inner ring need not slide smoothly on shaft.	All shaft diameters		h6	
Tapered bore bearing (Class 0; complete with adaptor or removable sleeve.)					
All types of loads		All shaft diameters		h9/IT5 [3)]	h10/IT7[3)] will suffice for power transmitting shafts.

1) Criteria for light loads, normal loads, and heavy loads.
- Light loads : Dynamic equivalent radial loads $\leq 0.05C_r$
- Normal loads : $0.05C_r$ < Dynamic equivalent radial loads $\leq 0.10C_r$
- Heavy loads : $0.10C_r$ < Dynamic equivalent radial loads

2) When using shaft diameter over 200 mm with heavy load or impact load, please contact **NTN** Engineering.
3) "IT5" or "IT7" means that the shaft form tolerance (circularity, cylidricity, etc.) must satisfy tolerance class IT5 or IT7.

Note 1 : The above table applies to solid steel shafts.

2 : When calculating the necessary interference, use the following expressions. Determine the value to 1/1000 the shaft diameter at maximum:
- When $F_r \leq 0.3C_{0r}$ Necessary interference Δd_F (μm) is $\Delta d_F = 0.08\ (d \cdot F_r/B)^{1/2}$
- When $F_r > 0.3C_{0r}$ $\Delta d_F = 0.02\ (F_r/B)$

(where, d: bearing bore diameter mm, B: inner ring width mm, F_r: radial load N, C_{0r}: basic static load rating N)

When taking into account the difference between the ambient temperature and the temperature of a running bearing, consider adopting the necessary temperature-difference-dependent effective interference Δd_T (μm).

$\Delta d_T = 0.0015 \cdot d \cdot \Delta T$

(where, ΔT: difference between bearing temperature and ambient temperature in ℃)

(2) Tolerance class of normally used housing bore

Conditions: Housing	Conditions: Load type, etc.		Conditions: Axial movement of outer ring	Tolerance class of housing bore	Remarks
One-piece housing or two-piece housing	Static outer ring load	All types of loads	Movable	H7	When a large bearing is used or a large temperature difference exists across the outer ring and housing, tolerance zone G7 may be applied.
		Light load[1)] or normal load[1)]	Movable	H8	——
		Shaft and inner ring become very hot.	Easily movable	G7	When a large bearing is used or a large temperature difference exists across the outer ring and housing, tolerance zone F7 may be applied.
One-piece housing		Precision rotation must be possibleunder light or normal load.	Generally immovable	K6	——
			Movable	JS6	——
		Quiet running required.	Movable	H6	——
	Indefinite-direction load	Light or normal load	Movable	JS7	——
		Normal or heavy load [1)]	Generally immovable	K7	——
		High-impact load	Immovable	M7	——
	Rotating outer ring load	Light or varying load	Immovable	M7	——
		Normal or heavy load	Immovable	N7	——
		Heavy or high-impact loads on thin-walled housings	Immovable	P7	——

1) Criteria for light loads, normal loads, and heavy loads.
- Light loads : Dynamic equivalent radial loads $\leq 0.05C_r$
- Normal loads : $0.05C_r$ < Dynamic equivalent radial loads $\leq 0.10C_r$
- Heavy loads : $0.10C_r$ < Dynamic equivalent radial loads

Note : The above table applies to steel or cast iron housings.

7 Allowable Axial Load

Spherical roller bearings carry a radial load, a bidirectional axial load, or a combination of both. They are suitable for applications involving vibration and impact loads. However , if spherical roller bearings are mounted on a vertical shaft or under an excessive axial load, the load on the rollers of the row not receiving the axial load will be reduced and the rollers in this row move with a sliding motion, possibly leading to lubrication failure and other problems. In case that the ratio of axial load to radial load exceeds Constant e which is in the dimension table ($F_a/F_r>e$), please contact **NTN** Engineering.

F_a : Axial load. F_r : Radial load. e : Constant (See dimension table)

8 Fatigue Load Limit (C_u)

The fatigue load limit is the applied load on a bearing that results in just reaching the fatigue stress limit at the maximum loaded raceway contact. This depends on the bearing type, internal specifications, quality, and material strength. In ISO 281:2007, 1.5 GPa is recommended as the fatigue stress limit corresponding to C_u for bearings made of commonly used high quality material and good manufacturing quality. Values for the fatigue load limit with respect to the **NTN** bearing numbers are provided in the dimensional table. The life modification factor, a_{ISO}, should be evaluated considering the fatigue load limit. For details see catalog "Ball and Roller Bearings (CAT. No.2203/E) section 3.4 Modified rating life".

9 Allowable Speed

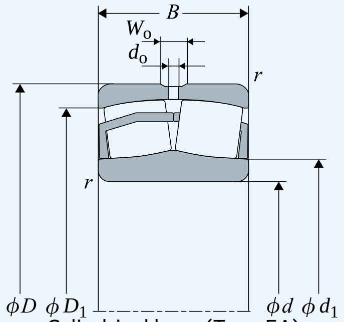
Higher rotational speed results in higher bearing temperatures caused by friction. When the bearing temperature exceeds a specific limit, lubricant performance deteriorates significantly, leading to abnormally high temperatures and bearing seizure.
The limiting factors that affect allowable rotational speed include the following:
(1) Bearing type
(2) Bearing size
(3) Lubrication system (grease, circulating lubrication, oil bath, etc.)
(4) Bearing internal clearance (internal clearance of running bearing)
(5) Bearing load
(6) Dimensional accuracy with shaft, housing, etc.
The allowable speeds indicated in the bearing dimension table are for reference only and apply only when bearings are lubricated and heat is efficiently drawn away from the bearing. The allowable speeds in this catalog are categorized as follows:

【Oil-lubricated bearings】
The rotational speed at which the outer ring temperature reaches 80 ℃ when the bearing is allowed to run at 5 % basic static load rating C_{0r} while lubricated with oil (viscosity ISO VG32) which is assimilated to room temperature and fed at a rate of 1 liter/min (circulating lubrication)

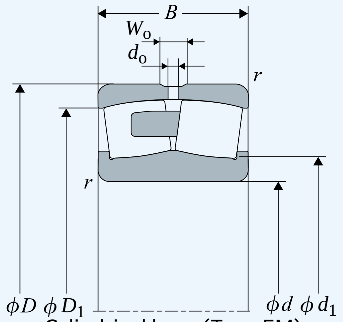
【Grease-lubricated bearings】
The rotational speed at which the outer ring temperature reaches 80 ℃ when the bearing, which has undergone running-in operation, is allowed to run at 5 % basic static load rating C_{0r} with the bearing's internal free volume 20 to 30 % pre-filled with lithium grease (consistency: NLGI3)
With either lubrication system, the bearing temperature rise profile varies with the operating conditions (operating load, rotational speed, lubricating conditions, etc.) in which the bearing is used. Therefore, select the optimal bearing by allowing sufficient margin for the allowable speed for that particular bearing as indicated in the catalog.
Contact **NTN** Engineering for technical assistance if the rotational speed in the intended application exceeds 80 % of the allowable speed indicated in the bearing dimension table, or if the intended bearing is to be used under severe operating conditions involving vibration and impact.

10 Dimension Table

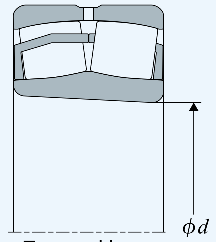
Type EA･Type EM



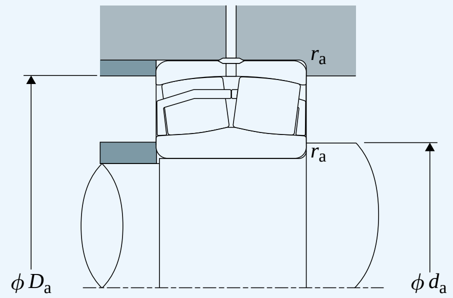
Cylindrical bore (Type EA)



Cylindrical bore (Type EM)



Tapered bore



Dynamic equivalent radial load

$P_r = XF_r + YF_a$

$\frac{F_a}{F_r} \le e$		$\frac{F_a}{F_r} > e$	
X	Y	X	Y
1	Y_1	0.67	Y_2

Static equivalent radial load

$P_{0r} = F_r + Y_0 F_a$

For values e, Y_1, Y_2 and Y_0 see the following table.

Boundary dimensions mm						Basic dynamic load rating kN	Basic static load rating kN	Fatigue load limit kN	Allowable speed min⁻¹		Bearing number		Abutment and fillet dimensions mm					Constant	Axial load factors			Mass (approx.) kg

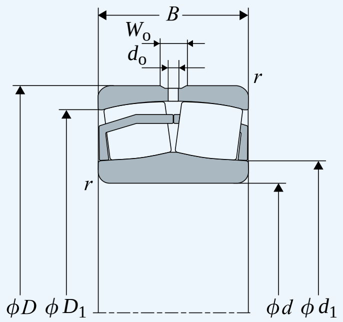
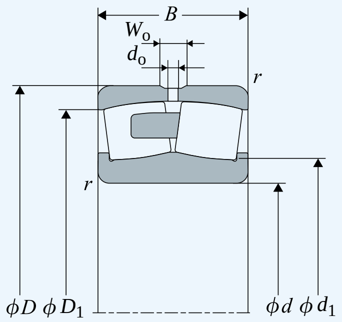
1) "K" indicates bearings have taperd bore with a taper ratio of 1:12.
2) Smallest allowable dimension for chamfer dimension r.

10 Dimension Table

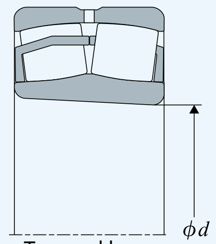
Type EA·Type EM



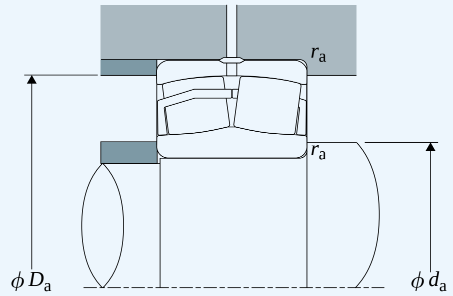
Cylindrical bore (Type EA)



Cylindrical bore (Type EM)



Tapered bore



Dynamic equivalent radial load

$P_r = XF_r + YF_a$

$\frac{F_a}{F_r} \le e$		$\frac{F_a}{F_r} > e$	
X	Y	X	Y
1	Y_1	0.67	Y_2

Static equivalent radial load

$P_{0r} = F_r + Y_0 F_a$

For values e, Y_1, Y_2 and Y_0 see the following table.

Boundary dimensions mm						Basic dynamic load rating kN	Basic static load rating kN	Fatigue load limit kN	Allowable speed min⁻¹		Bearing number		Abutment and fillet dimensions mm					Constant	Axial load factors			Mass (approx.) kg	
d	D	B	$r_{s\,min}$[2]	W_o	d_o	C_r	C_{0r}	C_u	Grease	Oil	Cylindrical bore	Tapered bore[1]	d_1	$d_{a\,min}$	$D_{a\,max}$	D_1	$r_{as\,max}$	e	Y_1	Y_2	Y_0	Cylindrical bore	Tapered bore

1) Bearings appended with "K" have a tapered bore ratio of 1:12; bearings append with "K30" have a tapered bore ratio 1:30.
2) Smallest allowable dimension for chamfer dimension r.

10 Dimension Table

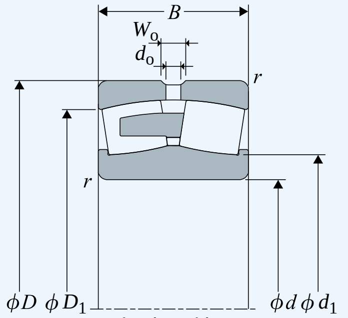
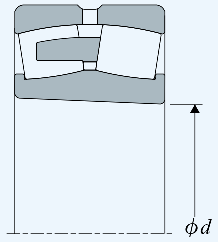
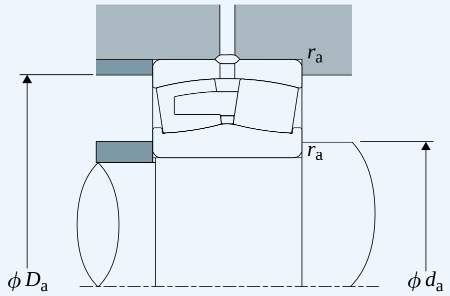
Type EM (Large size)



Cylindrical bore



Tapered bore



Dynamic equivalent radial load

$P_r = XF_r + YF_a$

$\frac{F_a}{F_r} \le e$		$\frac{F_a}{F_r} > e$	
X	Y	X	Y
1	Y_1	0.67	Y_2

Static equivalent radial load

$P_{0r} = F_r + Y_0 F_a$

For values e, Y_1, Y_2 and Y_0 see the following table.

Boundary dimensions mm						Basic dynamic load rating kN	Basic static load rating kN	Fatigue load limit kN	Allowable speed min⁻¹		Bearing number		Abutment and fillet dimensions mm					Constant	Axial load factors			Mass (approx.) kg	
d	D	B	$r_{s\,min}$ 2)	W_0	d_0	C_r	C_{0r}	C_u	Grease	Oil	Cylindrical bore	Tapered bore 1)	d_1	$d_{a\,min}$	$D_{a\,max}$	D_1	$r_{as\,max}$	e	Y_1	Y_2	Y_0	Cylindrical bore	Tapered bore

Spherical Roller Bearings with High-strength Cage

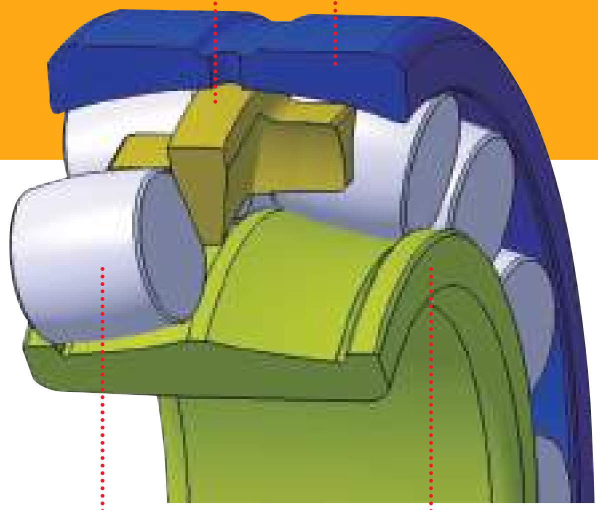
【EMA Type】

Industrial machineries are typically used under extremely severe operating conditions (eccentric rotation and impact load, for example). ULTAGE® series spherical roller bearings with a high-strength cage [EMA type] are our new standard series bearings developed to satisfy the needs of such heavy-duty machineries for improvements in "long life", "vibration resistance”, and "low temperature rise" characteristics.

Cage
- One-piece machined cage with staggered pockets
- Outer-ring-guided

Outer ring
- Optimum curvature
- Oil groove/hole provided



Rollers
- Large-diameter rollers
- The largest number of rollers

Inner ring
- Optimum curvature
- No inner ring flange

Improved vibration resistance
- High strength cage
- Outer-ring-guided cage more resistant to vibration and eccentric rotation
- Special specification available for vibration screens

Long life
- Load capacity of the world's highest level
- Extended maintenance intervals
- Downsizing and light-weighting opportunities
- Heat resistant up to 200˚C

Reduced temperature rise
- Permitted rotational speed of the world’s highest level
- Optimized internal bearing design including curvature

"ULTAGE®" (a name created from the combination of **"Ultimate,"** signifying refinement,and **"Stage,"** signifying **NTN**'s intention that this series of products be employed in diverse applications) is the general name for **NTN**'s new generation of bearings that are noted for their industry-leading performance.

Accuracy and Clearance (Vibration Screen Specification)

This is a bearing specification for vibration screen applications. Inner and outer diameter tolerances and radial internal clearance are adjusted to set adequate running internal clearance levels.
For information about bearing specifications (accuracy, clearance, etc.) for other applications than vibration screens, please see CAT. No. 3033/E: ULTAGE® series spherical roller bearings [EA type] and [EM type].

❶ Minimal allowable dimension for chamfer dimension r .

Allowable Axial Load

● $F_a / F_r \leqq e$

F_a : axial load, F_r : radial load, e : constant (ref. the list of dimensions)

If the bearing is used under excessive axial load, the rollers receive smaller radial load in the row not subjected to the axial load, which may cause the rollers to slide and eventually damage the bearing. When the ratio of axial load to radial load exceeds constant e in the list of bearing dimensions (i.e., $F_a/F_r > e$), please consult with **NTN**.

Allowable Self-aligning Angle

● $0.06C_r <$ dynamic equivalent radial load: 0.009rad (0.5°)

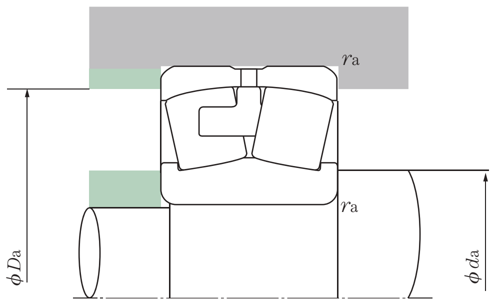
● Dynamic equivalent radial load $\leqq 0.06C_r$: 0.035rad (2°)

＊If self-aligning angle is too large, the rollers may stick out of the outer ring and hit against nearby parts. Special attention should be paid when setting self-aligning angles.

Bearing number

2 23 20 EMA K D1 VS1

- VS1: Vibration screen specification, no code means general bearing clearance and accuracy
- D1: Oil hole/groove code (D1: oil hole/ groove provided)
- K: Raceway shape code (no code: cylindrical bore, K: tapered bore)
- EMA: Type code (EMA: high strength cage)
- 20: Bore diameter number (20: 100mm)
- 23: Dimension series number
- 2: Bearing type code (2: spherical roller bearing)



Equivalent radial load
dynamic

$P_r = XF_r + YF_a$

$\frac{F_a}{F_r} \leqq e$		$\frac{F_a}{F_r} > e$	
X	Y	X	Y
1	Y_1	0.67	Y_2

static

$P_{0r} = F_r + Y_0 F_a$

For values of e, Y_1, Y_2, and Y_0 see the table below.

Bearing number	Abutment and fillet dimensions					constant	Axial load factor			Mass (approx.) kg

Features

1. Load capacity of the world's highest level

Maximizing the size and the number of the rollers achieved high load capacity and long life.

- Basic dynamic load rating: max. **20% up** (vs. our conventional bearing)
- Long life: max. **2X** (vs. our conventional bearing)

2. High strength cage

Modifying its shape and incorporating staggered pockets increased cage strength.

- Cage strength: max. **55% up** (vs. our conventional bearing)

3. Low heat-generation

Optimizing internal bearing design including curvature reduced temperature rise.

- Temperature rise: max. **10% down** (vs. our conventional bearing)

4. Heat resistant up to 200˚C

Being heat-treated by a special method, these bearings exhibit excellent dimensional stability at high temperatures, contributing to extended service life.

※Our conventional design refers to UA type bearings

Performance Test Data

Temperature rise test

[**Test conditions**]

- Bearing number: **22316** (80D X 170D X 58)
- Vibrational acceleration: 10G
- Rotational speed: 800 to 2,400min^{-1}
- Operating time: up to the point where temperature rise stabilizes
- Lubrication: oil lubrication
- Testing machine: please see **Fig. 1**

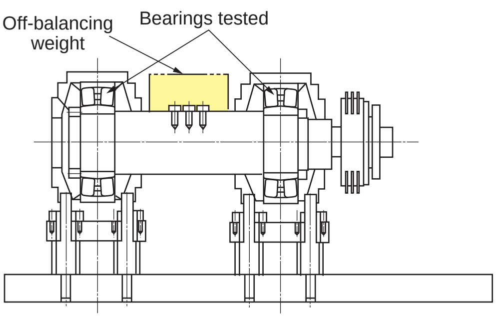

Fig. 1 Structure of testing machine

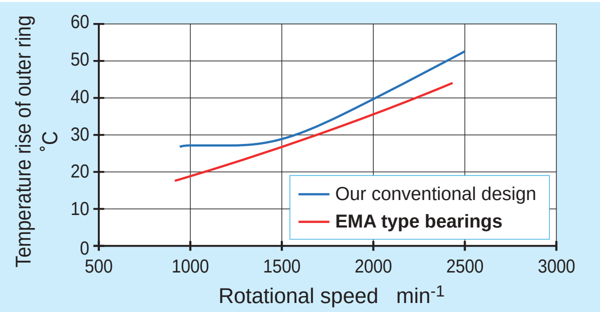
[**Test results**]



Cage strength analysis

[**Analysis conditions**]

- Bearing number: **22316** (80D X 170D X 58)
- Vibrational acceleration: 100G

＊This cage strength analysis is designed to predict the stress generated in the cage when vibrational acceleration of 100G is exerted on the bearing as impact load.

Bearing	Analysis model	Cage strength
Our conventional design		1
EMA type bearings		1.55

＊The cage strength of each bearing is expressed in terms of the cage strength of our conventional bearing taken as 1.

Warranty

NTN warrants, to the original purchaser only, that the delivered product which is the subject of this sale (a) will conform to drawings and specifications mutually established in writing as applicable to the contract, and (b) be free from defects in material or fabrication. The duration of this warranty is one year from date of delivery. If the buyer discovers within this period a failure of the product to conform to drawings or specifications, or a defect in material or fabrication, it must promptly notify **NTN** in writing. In no event shall such notification be received by **NTN** later than 13 months from the date of delivery. Within a reasonable time after such notification, **NTN** will, at its option, (a) correct any failure of the product to conform to drawings, specifications or any defect in material or workmanship, with either replacement or repair of the product, or (b) refund, in part or in whole, the purchase price. Such replacement and repair, excluding charges for labor, is at **NTN**'s expense. All warranty service will be performed at service centers designated by **NTN**. These remedies are the purchaser's exclusive remedies for breach of warranty.

NTN does not warrant (a) any product, components or parts not manufactured by **NTN**, (b) defects caused by failure to provide a suitable installation environment for the product, (c) damage caused by use of the product for purposes other than those for which it was designed, (d) damage caused by disasters such as fire, flood, wind, and lightning, (e) damage caused by unauthorized attachments or modification, (f) damage during shipment, or (g) any other abuse or misuse by the purchaser.

THE FOREGOING WARRANTIES ARE IN LIEU OF ALL OTHER WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE.

In no case shall **NTN** be liable for any special, incidental, or consequential damages based upon breach of warranty, breach of contract, negligence, strict tort, or any other legal theory,and in no case shall total liability of **NTN** exceed the purchase price of the part upon which such liability is based. Such damages include, but are not limited to, loss of profits, loss of savings or revenue, loss of use of the product or any associated equipment, cost of capital, cost of any substitute equipment, facilities or services, downtime, the claims of third parties including customers, and injury to property. Some states do not allow limits on warranties, or on remedies for breach in certain transactions. In such states, the limits in this paragraph and in paragraph (2) shall apply to the extent allowable under case law and statutes in such states.

Any action for breach of warranty or any other legal theory must be commenced within 15 months following delivery of the goods.

Unless modified in a writing signed by both parties, this agreement is understood to be the complete and exclusive agreement between the parties, superceding all prior agreements, oral or written, and all other communications between the parties relating to the subject matter of this agreement. No employee of **NTN** or any other party is authorized to make any warranty in addition to those made in this agreement.

This agreement allocates the risks of product failure between **NTN** and the purchaser. This allocation is recognized by both parties and is reflected in the price of the goods. The purchaser acknowledges that it has read this agreement, understands it, and is bound by its terms.

NTN Ball Bearings

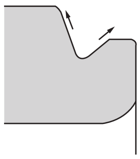
Shield and Seal Types

Machinery is being made smaller and more compact; the same is demanded of bearings.
NTN seal and shield type ball bearings are built to meet these trends.
They simplify shaft design, are maintenance-free, and are the bearing of choice for an increasing number of applications.

INDEX

1 Grooved Type Sealing figure for Excellent Performance〔all models〕

A v-shaped groove is cut around the inner ring. Under centrifugal force, the outer surface of the v acts to keep out dirt; the inner surface of the v acts to seal in the grease.

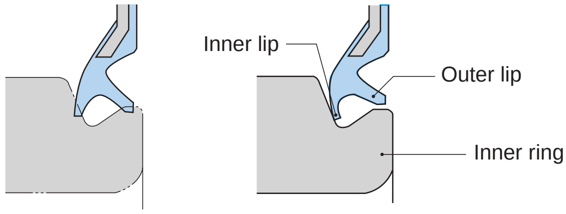


2 Rust Resistant Shield〔ZZ spec〕

In order to obtain rust resistant properties, the shield is made of a strip steel covered by a hard surface-coating. This assures long bearing service life and minimal noise levels.

3 Double-lip Seal Adjusts for Wear〔LLU spec〕

The inner lip of a double-lip seal is pressed against the inside surface of the V-groove; the outer lip is spread open by the elastic force of rubber to create a small gap between the outer lip and the inner ring. Should the inner lip wear, the contact pressure will decrease; however, the outer lip will get closer to the inner ring. In effect, a constant degree of sealing will be maintained; and, as a result, bearing service life will be noticeably lengthened.



1. Bearing Design and Features, Seal/Shield Bearing Types and Selection

Table 1 Bearing design and futures

Type, code no.		Shield type	Seal type		
		Non-contact type ZZ	Non-contact type LLB	Contact type LLU	Low torque type LLH
Construction							• Metal shield plate is affixed to outside ring; inner ring incorporates a V-groove and labyrinth clearance.	• Outer ring incorporates synthetic rubber molded to a steel plate; seal edge is aligned with V-groove along inner ring surface with labyrinth clearance.	• Outer ring incorporates synthetic rubber molded to a steel plate; seal edge contacts V-groove along inner ring surface.	• Basic construction the same as LU type, but specially designed lip on edge of seal prevents penetration by foreign matter; low torque construction.
Performance comparison	Torque	Very Low	Very Low	Medium	Low
	Dust proofing	Good	Very Good	Best	Excellent
	Water proofing	Poor	Poor	Very good	Good
	High speed capacity	Same as open type	Same as open type	Limited by contact seals	Better than LLU-type
	Allowable temp.range ❶	Depends on lubricant	-25 ℃～120 ℃	-25 ℃～110 ℃	-25 ℃～120 ℃

❶ Please consult **NTN** Engineering about applications which exceed the allowable temperature range of products listed on this table.
Note : This chart lists double shielded and double sealed bearings, but single shielded (Z) and single sealed (LB, LU, LH) are also available.
Grease lubrication should be used with single shielded and single sealed bearings.

2. Test Data for Seal Performance

Friction torque and temperature rise test

Test Conditions
Bearings :6305
Grease :Shell Alvania 3,3.5g packed
Revolution :1800 r/min
Time :20 minutes
Load :radial load 29 N
Quantity tested :5 pcs. each

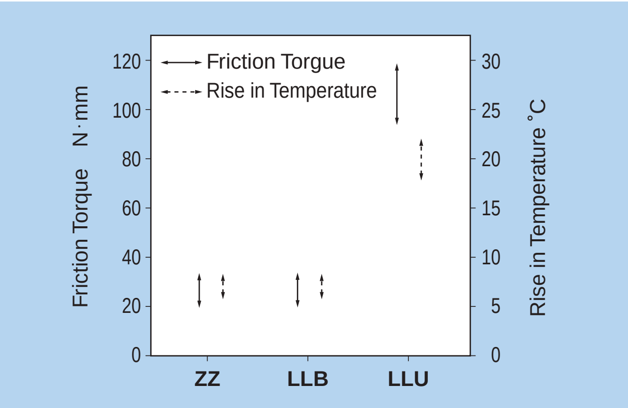

Figure 1. Friction torque and temperature rise test data

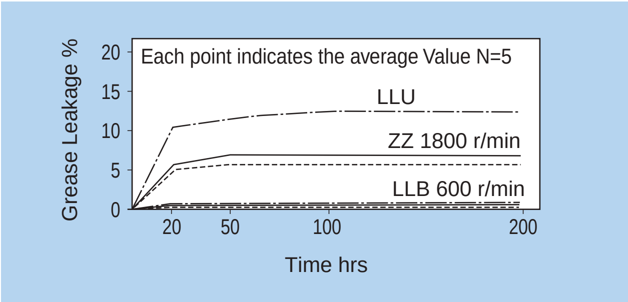
Grease leakage test

Test Conditions
Bearings :6305
Grease :Shell Alvania 3,3.5g packed
Revolution :1800 r/min, 600 r/min
Atmospheric temperature :80℃
Time :200 hrs
Quantity tested :5 pcs. each



The larger grease leakage with the LLU at 1800 rpm is due to bearing temperature rise.

Figure 2. Grease leakage test data

Dust test

Test Conditions
Bearings :6305
Grease :Shell Alvania 3,3.5g packed
Revolution :1800 r/min
Load :radial load 29 N
Volume of testing machine :40 liter
Dust :Oxidized ferrous powder (2kg) + lime (1.0kg) mixture
Time :1 hour

Table 3 Dust resistance test data

1 : Presence of dust clearly observed

Muddy water splash test

Test Conditions
Bearings :6304
Grease :Shell Alvania 3,2g packed
Revolution :3000 r/min
Muddy water :5 wt% of class 8 of JIS Z 8901 Kanto loam powder
Muddy water flow :30 cc/min
Test time :10 cycles over 240 hrs (Each cycle consists of 3 hours of spraying and 21 hours of drying)

Table 4 Muddy water splash test data

Type	1	2	3	4	5	average
LLU	3	2	2	4	3	2.8
LLB	2	1	1	2	2	1.6

Ratings 4 : No penetration whatsoever
3 : Very slight penetration of muddy water is apparent
2 : Some penetration of muddy water is apparent
1 : Considerable penetration of muddy water is apparent

3. Service Life of Prelubricating Grease

The service life of filled grease is influenced by many factors: operating conditions, temperature, atmosphere, etc. There is even a considerable difference by grease brands. Keeping this in mind, **Figure 3** presents a scale for determining grease service life. It is based on actual and experimental data; and applies to high-quality grease used in ball bearings under normal operating conditions.

As the working temperature increases, the grease life, of course, becomes shorter. Although not accurate for all greases, **Figure 3** is valid, in general, for working temperatures up to 80˚C; for working temperatures over 80˚C. service life decreases to about two-thirds for every 10˚ over 80˚C. (Please note that this does not apply to calcium-soap and aluminum-soap greases.)

Example

The following method is used to obtain the grease life of deep groove ball bearing 6206ZZ at a radial load of 1520 N and a operating speed, n, of 3600 r/min. From the appropriate Dimension Table we find that the standard load rating, Cr, for a 6206ZZ bearings is 19500 N and the limiting speed is 11000 r/min. (Use the value for ZZ or LLB even if the bearings of LLU specifications).

Divide Cr by the equivalent radial load, Pr. You will obtain 12.8 (19500/1520≈12.8). Next go to **Figure 4** to determine the value for f_L. (For Cr/Pr=12.8. f_L=1). Find $f_L \cdot n_0/n$. (1.0・11000/3600≈3.1).

With your value of $f_L \cdot n_0/n$' (3.1 in this example) go to **Figure 3** and find this value on Scale Ⅱ. Call this point B. The bore diameter, d, of the bearing is 30. Find this value on Scale Ⅰ and call this point A. Draw a straight line between Points A and B. The line will intersect Scale Ⅲ at some point which will be Called Point C. In this example, Point C is 17000 hours. This is the expected grease life of the bearing which is what we were looking for.

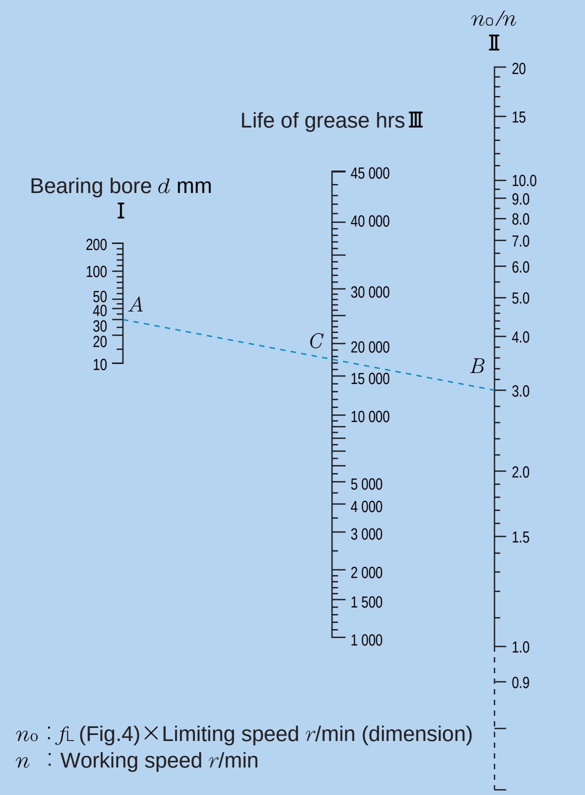

Figure 3

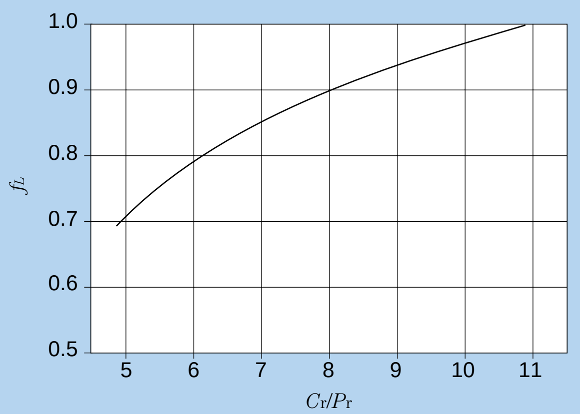

Figure 4 Correction coefficient f_L as a function of bearing load Cr/Pr

Note that **NTN** can also manufacture shield and seal type small diameter ball bearings of dimensions other than those shown on the subsequent dimension tables. Contact **NTN** for more information.

- **Use under high or low temperature**
- **Low torque is required**
- **High speeds are required**
- **Grease leakage must be avoided**
- **Use under other special conditions**

Also note that the performance of prelubricated ball bearings is affected by operating conditions and grease type. For information on performance under special conditions, please contact **NTN**.

4. Bearing Precision

Inner ring

d = Nominal bore diameter
Δ_{dmp} = Single plane mean bore diameter deviation
V_{dp} = Single radial plane bore diameter variation
V_{dmp} = Mean single plane bore diameter variation
K_{ia} = Inner ring radial runout
S_{d} = Face runout with bore
S_{ia} = Inner ring axial runout (with side)
Δ_{Bs} = Inner ring width deviation
V_{Bs} = Inner ring width varietion

Outer ring

D = Nominal outside diameter
Δ_{Dmp} = Single plane mean outside diameter deviation
V_{Dp} = Single radial plane outside diameter variation
V_{Dmp} = Mean single plane outside diameter variation
K_{ea} = Outer ring radial runout
S_{D} = Outside surface inclination
S_{ea} = Outside ring axial runout
Δ_{Cs} = Outer ring width deviation
V_{Cs} = Outer ring width variation

❶ The dimensional difference Δ_{ds} of bore diameter to applied for class 4 and 2 is the same as the tolerance of dimentional difference Δ_{dmp} of average bore diameter. However, the dimensional difference is applied to diameter series 0, 1, 2, 3 and 4 against Class 4, and to all the diameter series against Class 2.

ULTAGE®

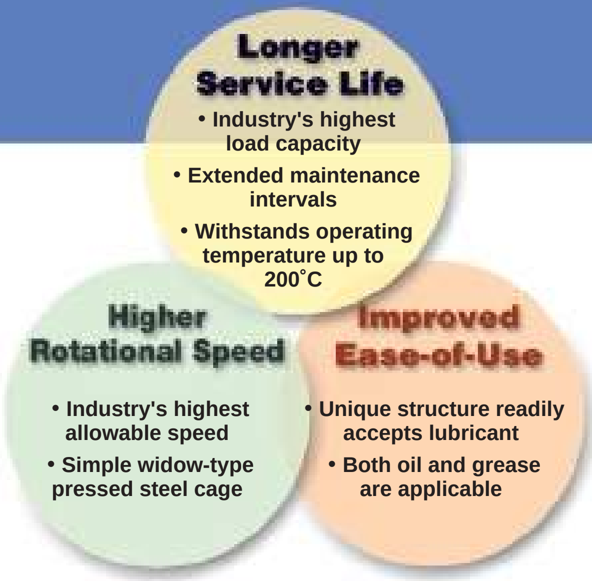
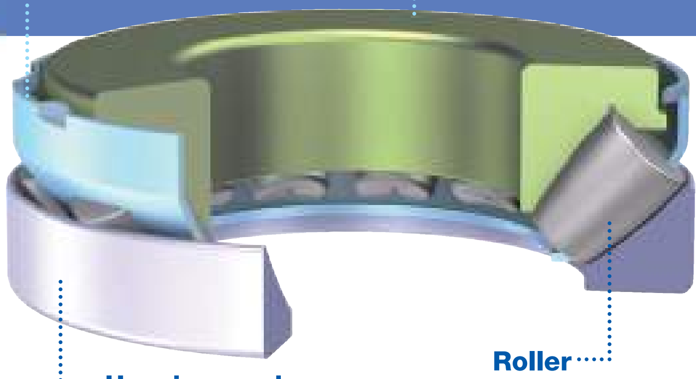
Up to Six times longer service life | **Up to 70% higher load capacity** | **Up to 20% higher allowable speed**

Thrust Spherical Roller Bearing

"ULTAGE series Thrust Spherical Roller Bearing" is a new series developed to satisfy customers' needs such as "longer service life", "higher rotational speed", "improved ease-of-use" required for all industrial applications.



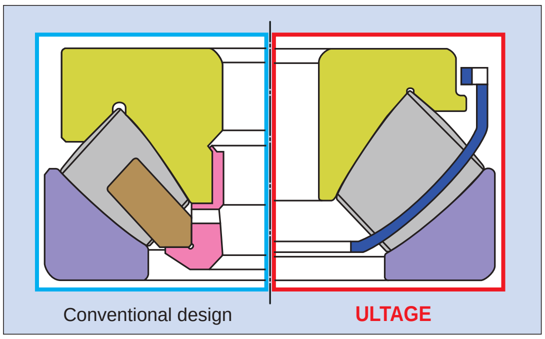


Advantages

1. Industry's highest load capacity

These bearings have a significantly increased roller diameter and incorporate the maximum number of rollers, thus achieving both a high load capacity and a longer service life.

- Basic dynamic load rating: **up to 70% greater** (vs. conventional design)
- Service life : **up to 6 times longer** (vs. conventional design)



2. Industry's highest allowable speed

The new pressed steel cage results in allowable speed up to **20% greater**. (vs. **NTN** conventional type)

3. Window-type pressed steel cage

With the new window-type pressed steel cage, both oil and grease lubrication are applicable.

4. Withstands operating temperature up to 200˚C

By adoption a special heat treatment, dimensional stability is achieved at high temperatures.

ULTAGE® **"ULTAGE® "** (a name created from the combination of **"ultimate,"** signifying refinement,and **"stage,"** signifying **NTN**'s intention that this series of products be employed in diverse applications) is the general name for **NTN**'s new generation of bearings that are noted for their industry-leading performance.

Bearing Tolerances

Allowable Speed

- The allowable speeds indicated in the bearing dimension table are for reference only and applied only when bearings are lubricated and heat is efficiently drawn away from the bearing.The allowable speeds in this catalog are categorized as follows:

【Oil lubricated bearings】

The bearing rotational speed at which housing washer temperature reaches 80˚C when the bearing is running under the load of 5% of basic static load rating C_{0a} while lubricated with oil (viscosity VG32) which is assimilated to room temperature and fed at a rate of 1 liter/min (circulating lubrication).

【Grease lubricated bearings】

The bearing rotational speed at which housing washer temperature reaches 80˚C when the bearing is running under the load of 5% of basic static load rating C_{0a} after the running in with the Lithium grease of which amount is 100% of the bearing internal free value (consistency : NLGI3).

With either lubrication system, the bearing temperature rise profile varies with operating conditions (load, speed, lubrication, etc.). Therefore, select the bearing with sufficient margin from allowable speed in the catalog.

Please contact **NTN** Engineering for technical assistance if the bearing speed might exceeds 80% of the allowable speed indicated in the catalog.

Lubricating methods

- Due to the nature of the design in thrust spherical roller bearings, lubrication may not be distributed thoroughly between the inner ring and the large end roller side face. So, it is imperative to supply sufficient lubricant to the bearing.
For grease lubrication, fill the bearings' and hougings' effective space with grease (ref. **Fig.1** and **Fig. 2**).

[Vertical shaft]
Bearing : 100% of effective space (**Fig.1** -①)
Housing : 100% of the volume (**Fig.1** -②③)

NTN®

Cylindrical Roller Bearings
ULTAGE Series

CAT.No.3037-3/E

ULTAGE™

Rating life +20 % (max.) | **Basic dynamic load rating +7 % (max.)** | **Allowable speed +20 % (max.)**

ULTAGE™

Cylindrical Roller Bearings ULTAGE Series

Cylindrical roller bearings of ULTAGE series are products developed to provide longer service life, increase of load capability, and higher rotational speed required for any industrial machinery.

Higher Reliability

- Greater load capacity by optimizing internal specifications
- Extended maintenance intervals

Increase of Load Capability

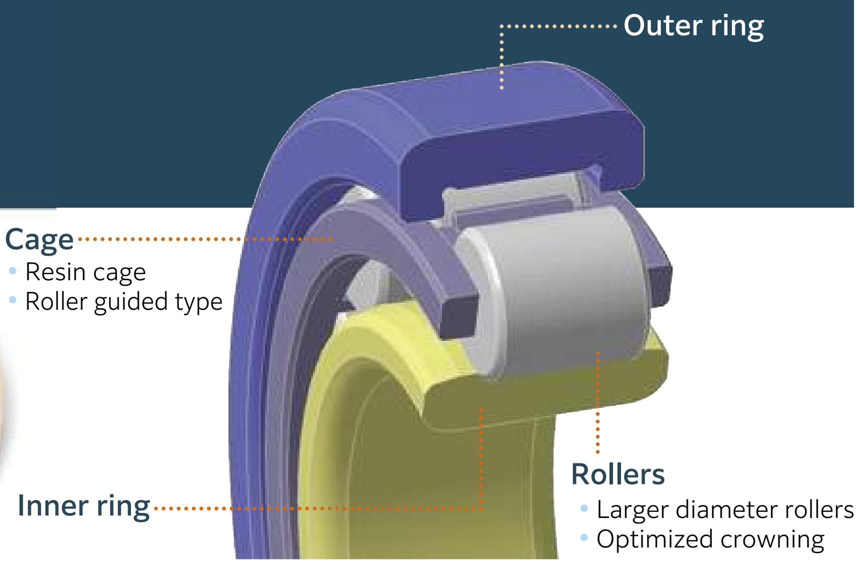
- Allowable misalignment 1/500

※Under conditions of $F_r \leq 0.20\ C_r$
F_r : Radial load

Higher Limiting Speed

- max. 20 % increase of allowable speed by optimizing internal specifications

※With oil lubrication



Features

1. World's highest level load carrying capacity

Higher load carrying capacity and longer rating life by optimizing internal specifications

(1) Rating life : max. +20 % (compared to conventional NTN E type)

(2) Basic dynamic load rating : max. +7 % (compared to conventional NTN E type)

2. Allowable misalignment (see Fig. 1)

Allowable misalignment : 1/500

Optimized crowning allows combination of $0.20C_r$ and misalignment up to 1/500 to be used. When the radial load exceeds $0.20C_r$, please ask **NTN**. *Minimum required load: $0.04C_{0r}$.
C_r means basic dynamic load rating, and C_{0r} means basic static load rating listed in this catalog.

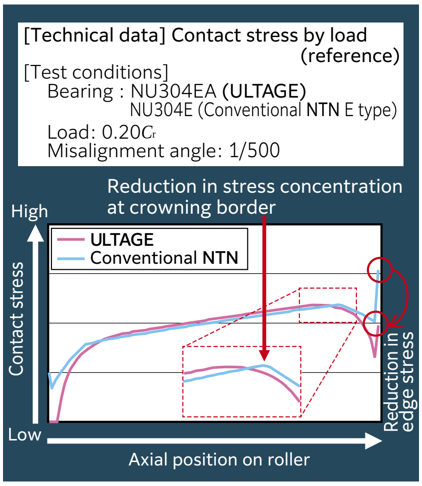


Fig. 1

3. Allowable speed

max. +20 % with oil lubrication (compared to conventional **NTN** E type)

4. Adopted resin cage as standard (see Fig. 2)

(1) Standard use of integrated polyamide resin cage results in higher limiting speed and longer life of grease.

(2) Resin cage material: polyamide reinforced with glass fiber.

*If machined cage for high speed is required, please ask **NTN**.

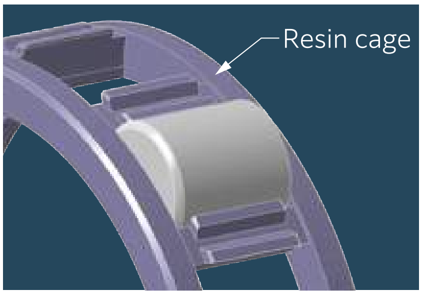

Fig. 2

5. Interchangeability

Boundary dimensions comply with ISO 15, JIS B 1533, DIN 5412, and the dimensions of these bearings are also same as conventional **NTN** E type.

6. Allowable axial load

Same as conventional **NTN** E type.

7. Allowable temperature

Allowable temperature of bearings : 120 ˚C (instantaneous), 100 ˚C (continuous)

ULTAGE™ "ULTAGE" (a name created from combination of "**Ultimate**", signifying refinement, and "**Stage**", signifying NTN's intention that this series of products be employed in diverse applications) is the general name for NTN's new generation of bearings that are noted for their industry leading performance.

Allowable axial load

Cylindrical roller bearings with ribs on the inner and outer rings are capable of simultaneously bearing a radial load (F_r) and a certain degree of axial load (F_a). Unlike basic dynamic load ratings based on rolling fatigue, allowable axial load (F_a max) is defined by the following two methods. When determining the actual allowable axial load, the smaller value out of P_t and F_{ar} determined with formula (1) and formula (2) is used.

① Allowable axial load P_t based on allowable surface pressure of rib

This is the allowable axial load that is determined by factors such as the amount of heat produced on the sliding surface between the ends of the rollers and rib, seizure and wear. The allowable axial load P_t based on allowable surface pressure of rib when center axial load is applied is approximately determined by formula (1), which is based upon experience and testing.

$$P_t = k_1 \cdot d^2 \cdot P_z \quad \cdots\cdots (1)$$

Where:

P_t : Allowable axial load based on allowable surface pressure of rib N

k_1 : Factor determined by internal design of bearing (see **Table 1**)

d : Bearing bore mm

P_z : Allowable surface pressure of rib MPa (see **Fig. 3**)

② Allowable axial load F_{ar} based on radial load

If the ratio of the axial load to the radial load is large, the rollers will not rotate properly. The allowable axial load F_{ar} based on the radial load is determined by formula (2).

$$F_{ar} = k_2 \cdot F_r \quad \cdots\cdots (2)$$

Where:

F_{ar} : Allowable axial load based on radial load N

k_2 : Factor determined by internal design of bearing (see **Table 1**)

F_r : Radial load N

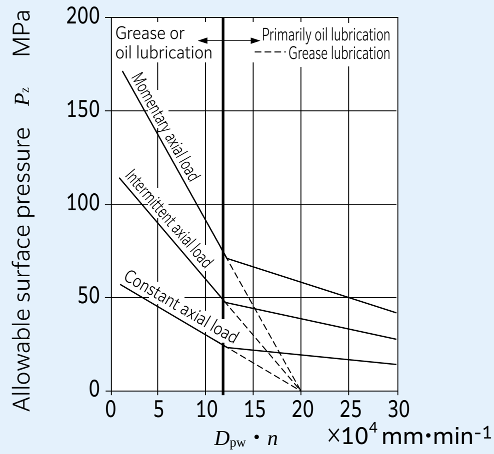
The following are also important to operate the bearing smoothly under axial load:

(1) Do not make the internal radial clearance any larger than necessary.

(2) Use lubricant with extreme pressure additive.

(3) Make the shoulder of the housing and shaft high enough for the rib of the bearing.

(4) If the bearing is to support an extreme axial load, mounting precision should be improved and the bearing should rotate slowly before actual use.



D_{pw} : Roller pitch diameter mm

$D_{pw} \approx$ (bearing bore + bearing outside diameter)/2 mm

n : Rotational speed min^{-1}

Fig. 3 Allowable surface pressure of rib

NJ, NUP, NF23EA		

Fatigue Load Limit(C_u)

The fatigue load limit is the applied load on a bearing that results in just reaching the fatigue stress limit at the maximum loaded raceway contact. This depends on the bearing type, internal specifications, quality, and material strength. In ISO 281:2007, 1.5 GPa is recommended as the fatigue stress limit corresponding to C_u for bearings made of commonly used high quality material and good manufacturing quality. Values for the fatigue load limit with respect to the **NTN** bearing numbers are provided in the dimensional table. The life modification factor, a_{ISO}, should be evaluated considering the fatigue load limit. For details see catalog “Ball and Roller Bearings (CAT. No.2203/E) section 3.4 Modified rating life”.

Allowable speed

Higher bearing speeds result in higher bearing temperatures caused by friction. When the bearing temperature exceeds a specific limit, the lubricant performance deteriorates significantly, leading to abnormally high temperature and bearing seizure. The factors that affect the allowable bearing speed include the followings:

(1) Bearing type
(2) Bearing size
(3) Lubrication system (grease, circulating lubrication, oil bath, etc.)
(4) Bearing internal clearance (internal clearance of running bearing)
(5) Bearing load
(6) Dimensional accuracy with shaft, housing, etc.

The allowable speeds indicated in the bearing dimension table are for reference only and apply only when bearings are lubricated and heat is efficiently draw away from the bearing. The allowable speeds in this catalog are categorized as follows:

【Oil-lubricated bearings】

The bearing speed at which the outer ring temperature reaches 80 °C when the bearing is allowed to run at 5 % basic static load rating C_{0r} while lubricated with oil (viscosity ISO VG32) which is assimilated to room temperature and fed at a rate of 1 liter/min (circulating lubrication)

【Grease-lubricated bearings】

The bearing speed at which the outer ring temperature reaches 80 °C when the bearing, which has undergone running-in operation, is allowed to run at 5 % basic static load rating C_{0r} with the bearing’s internal free volume 20 to 30 % pre-filled with lithium grease (consistency: NLGI3)

With either lubrication system, the bearing temperature rise profile varies with the operating conditions (operating load, running speed pattern, lubricating conditions, etc.) in which the bearing is used. Therefore, select the optimal bearing by allowing sufficient margin for the allowable speed for that particular bearing as indicated in the catalog. Contact **NTN** for technical assistance if the bearing speed in the intended application exceeds 80 % of the allowable speed indicated in the bearing dimension table, or if the intended bearing is to be used under severe operating conditions involving vibration and impact.

Allowable misalignment

Allowable misalignment: 1/500

∗Under conditions of: $F_r \leq 0.20C_r$ C_r means basic dynamic load rating listed in this catalog.

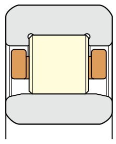
Bearing number

NU 22 04 EA T2X C3

- Radial internal clearance : C3
- Cage code : resin cage
- Type code : ULTAGE
- Nominal bore diameter : 20 mm
- Dimension series : 22
- Bearing series : cylindrical roller bearing NU type

∗ Suffix "U" is added at the end of bearing number for NUP type.

Bearing series



Components of NU type
- Outer ring (with double ribs)

Note 1) "CN" is not indicated on bearing number
2) Non-interchangeable clearance
3) For bearings with normal clearance, only NA is added to bearing numbers. Example: NU310EAT2XNA

Bearing Fits

General standards of bearing fits for each condition of use are shown in **Table 8** to **Table 10**.

Table 8 Tolerance class of shafts commonly used for cylindrical roller bearings (classes 0 and 6)

Conditions		Shaft diameter (mm) over	Shaft diameter (mm) incl.	Shaft tolerance class	Remarks
Inner ring rotational load or load of undermind direction	Light load[1] or fluctuating load	—	40	js6	When greater accuracy is required js5, k5, and m5 may be substituted for js6, k6, and m6.
		40	140	k6	
	Ordinary load[1]	—	40	k5	—
		40	100	m5	
		100	140	m6	
	Heavy load[1] or impact load	50	140	n6	Use bearings with larger internal clearances than CN clearance bearings.
Inner ring static load	Inner ring must move easily over shaft	Overall shaft diameter		g6	When greater accuracy is required use g5. For large bearings, f6 will suffice for to facilitate movement.
	Inner does not have to move easily over shaft	Overall shaft diameter		h6	When greater accuracy is required use h5.
Center axial load		Overall shaft diameter		js6	Generally, shaft and inner rings are not fixed using interference.

Note All values and fits listed in the above tables are for solid steel shafts.

Table 9 Tolerance class of housing bore commonly used for cylindrical roller bearings (classes 0 and 6)

Conditions: Housing	Conditions: Types of load		Conditions: Outer ring axial direction movement[2]	Tolerance class of housing bore	Remarks
Single housing or split housing	Outer ring static load	All types of loads	Yes	H7	G7 can be used for large bearings or bearings with large temperature differential between the outer ring and housing.
		Light load[1] or ordinary load[1]	Yes	H8	—
		Shaft and inner ring become hot.	Easily	G7	F7 can be used for large bearings or bearings with large temperature differential between the outer ring and housing.
Single housing		Requires precise rotation under light or ordinary loads	As a rule, cannot move.	K6	Primarily applies to roller bearings.
			Yes	JS6	—
		Requires low noise operation	Yes	H6	—
	Indeterminate load	Light or ordinary load	Yes	JS7	If high accuracy is required, JS6 and K6 are used in place of JS7 and K7
		Ordinary load or heavy load[1]	As a rule, cannot move.	K7	
		High impact load	No	M7	—
	Outer ring rotational load	Light or fluctuating load	No	M7	—
		Ordinary or heavy load	No	N7	—
		Heavy load or large impact load with thin wall housing	No	P7	Primarily applies to roller bearings.

Remarks ●All values and fits listed in the above tables are for cast iron or steel housings.
●If only center axial load is applied of the bearings, select a tolerance class provides clearance for the outer ring in the axial direction.

Note 1) Standards for light loads, normal loads, and heavy loads
Light loads : equivalent radial load $\leq 0.05\ C_r$
Normal loads : $0.05\ C_r <$ equivalent radial load $\leq 0.10\ C_r$
Heavy loads : $0.10\ C_r <$ equivalent radial load
2) Indicates whether or not outer ring axial movement is possible with non-separable type bearings.

Table 10 Fits for electric motor bearings

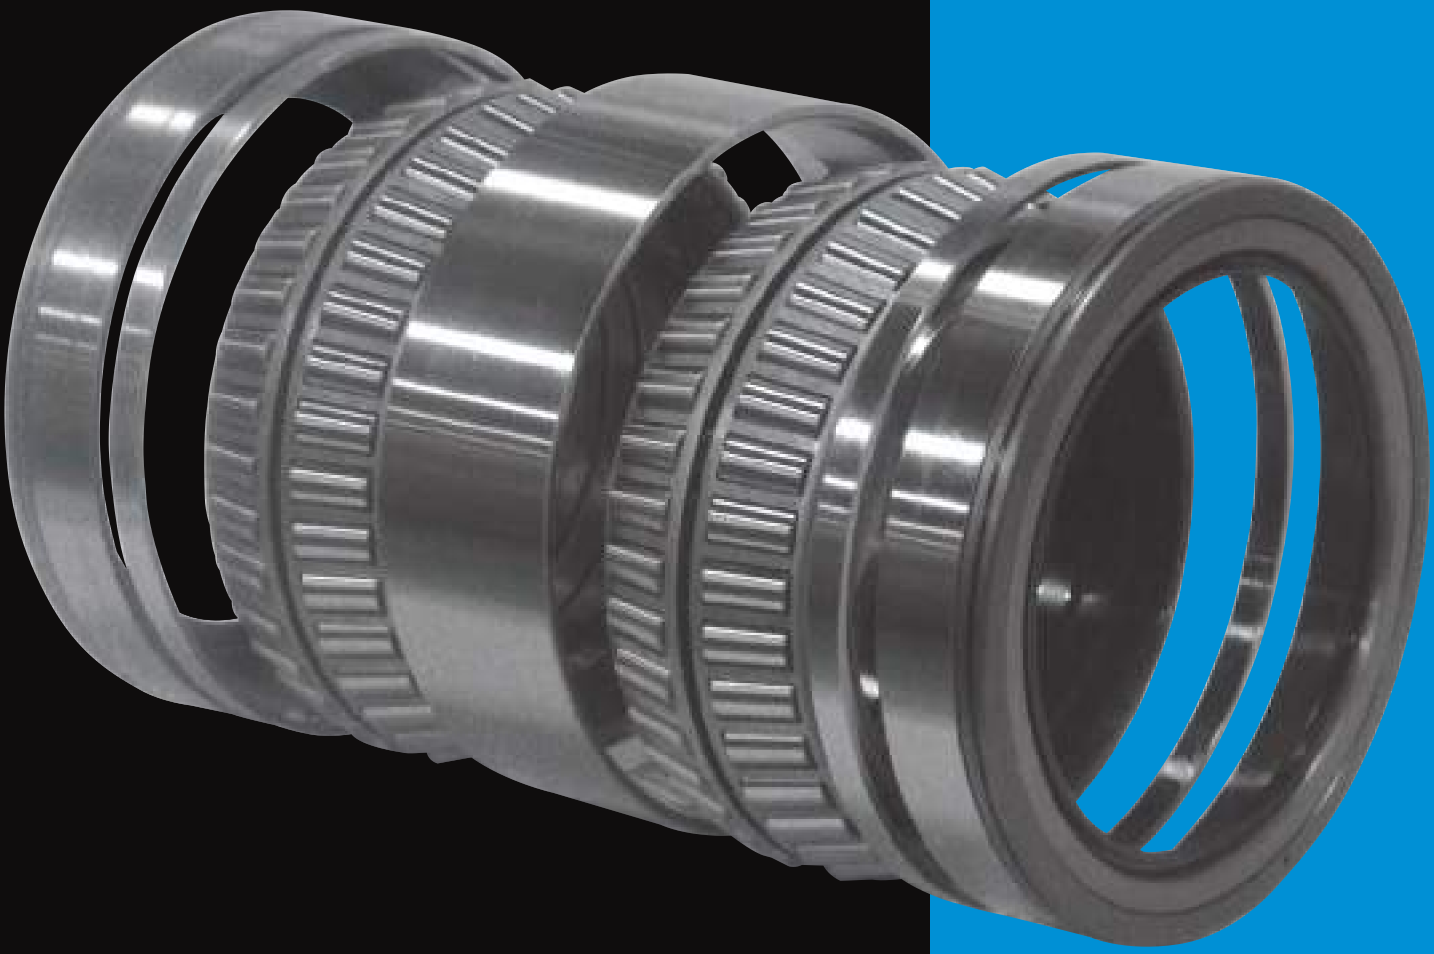
Sealed Four Row Tapered Roller Bearings for Rolling Mill Roll-Necks

[CROU..LL Type]



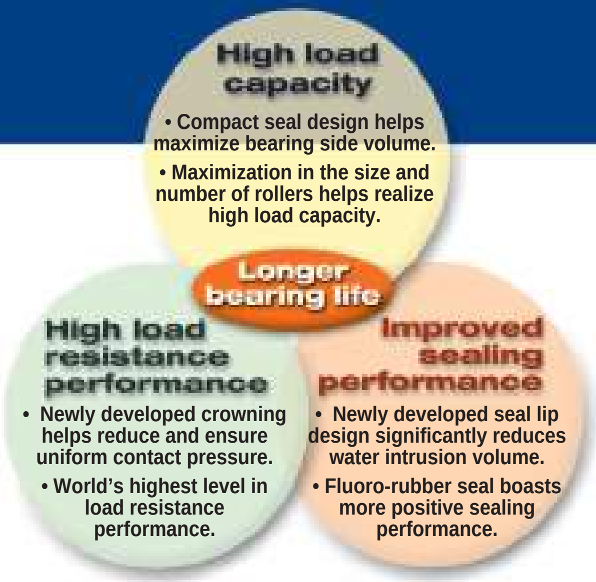
ULTAGE®

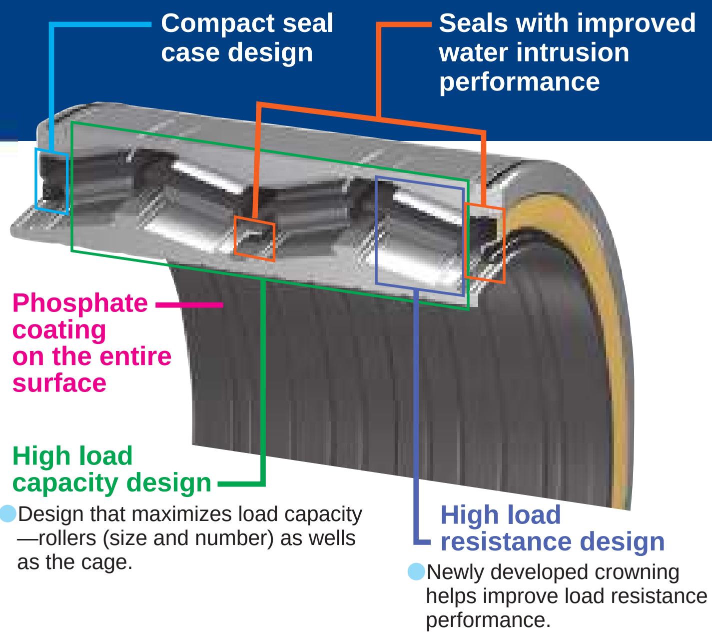
CAT. No. 3801/E

Load capacity 40% increase | Load resistance Twice as great | Sealing performance 50% reduction in water intrusion volume

Sealed Four Row Tapered Roller Bearings for Rolling Mill Roll-Necks [CROU..LL Type]

The ULTAGE series sealed four row tapered roller bearings (CROU..LL type) are new standard series products especially developed to satisfy the "high load capacity", "high load resistance performance" and "high sealing performance" required for steel mill roll-neck applications and to improve reliability through long life design.





Features

1. High load capacity design —the world's highest level

Maximum size and number of rollers help realize high load capacity and longer life.

2. High load resisting design —the world's highest level

Patent pending

Assurance of uniform contact pressure on rolling elements within bearings and against outside loads has helped greatly enhance load resistance performance.

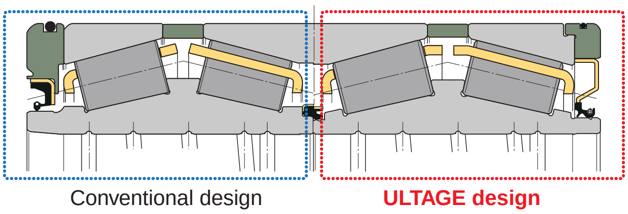
3. Compact high sealing design

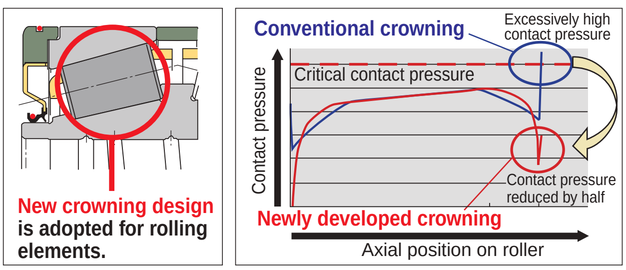
Patent pending

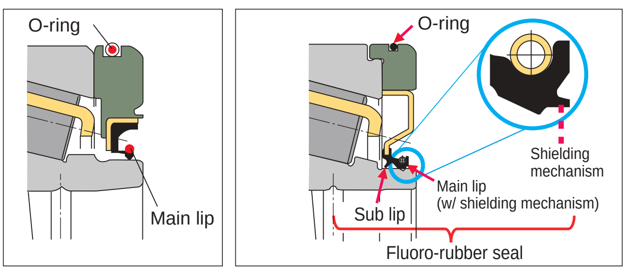
"High sealing" fluoro-rubber seals, boasting a minimized seal volume, are adopted as standard.
Through optimization of the tightening force of the main lip and the provision of a shielding arrangement against foreign substances, the water intrusion volume has been reduced by more than 50%: at the same time, the sub lip helps prevent the outflow of grease.

4. Long-life grease as standard

The bearing is prefilled with long-life grease.
A rinsing and/or grease prefilling procedure is not necessary when the bearing is installed on the side of the machine.







Conventional design   ULTAGE design

"ULTAGE®" (a name created from the combination of **"ultimate,"** signifying refinement,and **"stage,"** signifying **NTN**'s intention that this series of products be employed in diverse applications) is the general name for **NTN**'s new generation of bearings that are noted for their industry-leading performance.

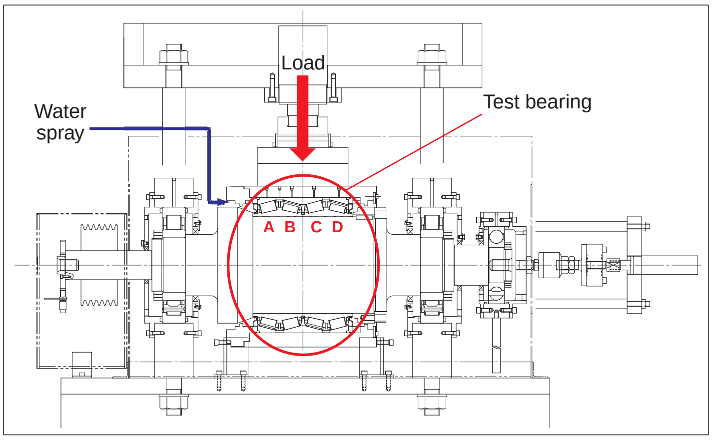
Performance Test Data

●Water Resistance Durability Test

[Test conditions]

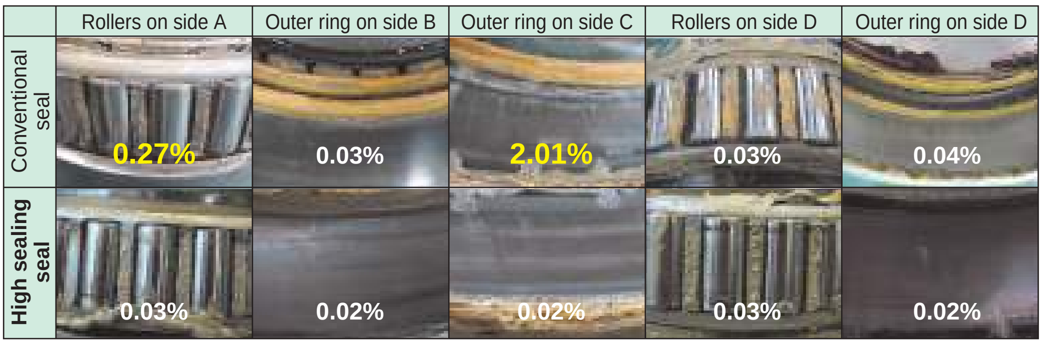
Bearing number: ULTAGE sealed four row tapered roller bearing CROU-6001LLAX1
(Dimensions: ϕ300×ϕ420×310, C_r: 3600 kN, C_{0r}: 7650 kN)
Prelubricating grease: Palmax RBG
Radial load: 390 kN (0.11 C_r)
Running speed: Cyclic operation where one cycle consists of ⇒300 min^{-1} (0.5 h) ⇒ 500 min^{-1} (1 h) ⇒ standstill (1 h)
Water spray: 0.15 L/min
Total running hours: 1000 h



Structure of test rig

[Status of bearing interior after test, and water content in grease (wt%)]

* Water content in factory-fresh grease is in the range of 0.001% to 0.04%.



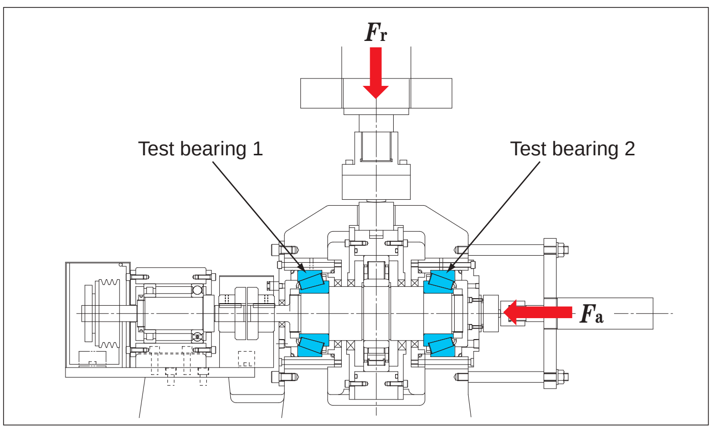
Appearance of test rig

Evidence of water intrusion is found on the conventional seal. In contrast, the NTN "high sealing" seal does not exhibit evidence of water intrusion.

●Life test result

[Test conditions]

Bearing number: Comparison of conventional design and ULTAGE in terms of life 30316U (dimensions: ϕ80×ϕ170×42.5)
Lubrication: Turbine Oil VG68, circulating lubrication
Combined radial and axial loads: 117 kN/bearing (0.4 C_r equivalent, radial load: 75 kN/bearing, axial load: 50 kN/bearing)
Running speed: 2000 min^{-1}
Misalignment: 1/600 (0.1°)



Structure of test rig

[Test result]

	Appearance of assembled inner ring	Appearance of outer ring	Status
Conventional design			Flaking occurred near the chamfered end of rollers as well as at the corresponding contact point on the outer ring. (L_{10} = 225 h)
ULTAGE			After termination of the test at 690 hours, the test bearing was free from any failures including flaking.

ULTAGE bearings boast a life 2.6 times as long as their design life, and twice as long as the life of conventional bearings, when both bearing types are tested under test conditions of 0.4 C_r and 1/600 misalignment.

Ball and Roller Bearings

CAT.No.2203/E

NTN "Ball and Roller Bearings Catalog"

Issue of CAT.No.2203/E

A rolling bearing is an important mechanical element that is used in various machines. Rolling bearings are required to have a long operating life, be small/lightweight, fast, and support special environments. Thus, the performance requirements are becoming more sophisticated and diversified. In particular, technology for enhancing the performance of bearing has been required in recent years. To meet these needs, **NTN** is performing research and development to enhance the performance of the entire machines.

The new general catalog has been entirely revised and edited so that the bearings of an optimum type and size can be provided based on the technical contents that are supported by the result of development and improvement.

The main revisions of the catalog are as follows.

- ○ The latest revision of ISO and JIS is reflected, and the pages of general commentaries such as bearing selection, bearing periphery design, and handling are largely increased.
- ○ Based on the results of in-house durability testing that has been accumulated over a long time, it has been confirmed that the bearing operating life is longer then previously published. Thanks to the continuous improvement of the material, product, and production techniques, the basic dynamic load ratings were revised based on the current bearing operating life data.
- ○ We are developing and expanding "ULTAGE," a new generation, all-world class rolling bearing series. This catalog introduces the ULTAGE series, which has been developed by **NTN** so far, and includes line-ups that are ready to be manufactured.

We would like you to use the "Ball and Roller Bearings Catalog" which has been revised, and we would like to work and develop with customers "to realize a smooth society". We hope to receive your continued patronage and support in the future.

Special bearings for each industry and application type are introduced in special sections at the end of the catalog. Please contact **NTN** Engineering for more information.

NTN

Ball and Roller Bearings

The CAD data of products is available on the **NTN** website. See our website for details.

TECHNICAL EXPLANATION CONTENTS

1. Classification and characteristics of rolling bearings

1.1 Structure

Most rolling bearings consist of **rings with a raceway** (inner ring and outer ring), **rolling elements** (either balls or rollers) and a **cage** as shown in **Fig. 1.1** (**Figs. A to H**). The cage separates the rolling elements at regular intervals, holds them in place within the inner and outer raceways, and allows them to rotate freely.

Raceway (inner ring and outer ring) or raceway washer[1] (shaft or housing)

The surface on which rolling elements roll is called the "**raceway surface**." The load placed on the bearing is supported by this contact surface.

Generally the inner ring fits on the axle or shaft and the outer ring in the housing.

Note 1: The raceway of thrust bearings is called the "raceway washer," the inner ring is called the "shaft raceway washer" and the outer ring is called the "housing raceway washer."

Rolling elements

Rolling elements are classified into two types: **balls** and **rollers**. Rollers come in four types: **cylindrical**, **needle**, **tapered**, and **spherical**. **Balls** geometrically contact with the raceway surfaces of the inner and outer rings at "**points**", while the contact surface of **rollers** is a "**line**" contact. Theoretically, rolling bearings are constructed to allow the rolling elements to rotate orbitally while also rotating on their own axes at the same time.

Cage

Cages function to maintain rolling elements at a uniform pitch so a load is never applied directly to the cage and to prevent the rolling elements from falling out when handling the bearing. Types of cages differ according to the way they are manufactured and include: **pressed**, **machined** and **formed cages**.

1.2 Classification

Rolling bearings are divided into two main classifications: **ball bearings** and **roller bearings**. Ball bearings are classified according to their bearing ring configurations: **deep groove type** and **angular contact type**. Roller bearings on the other hand are classified according to the shape of the rollers: **cylindrical**, **needle**, **tapered** and **spherical**. Rolling bearings can be further classified according to the direction in which the load is applied; **radial bearings** carry radial loads and **thrust bearings** carry axial loads. Other classification methods include: 1) number of rolling rows (**single**, **double**, or **4-row**), 2) **separable** and **non-separable**, in which either the inner ring or the outer ring can be detached.

There are also bearings designed for special applications, such as: precision rolling bearings for machine tools, bearings for special environments, as well as linear motion bearings (linear ball bearings, linear roller bearings and linear flat roller bearings). Types of rolling bearings are given in **Fig. 1.2**. For more detailed information, please refer to the page that introduces each bearing.

1.3 Characteristics

1.3.1 Characteristics of rolling bearings

Rolling bearings come in many shapes and varieties, each with its own distinctive features. However, when compared with sliding bearings, rolling bearings all have the following advantages:

(1) The **starting friction coefficient** is lower and there is little difference between this and the **dynamic friction coefficient**.

(2) They are internationally standardized, **interchangeable** and readily obtainable.

(3) They are easy to lubricate and consume less **lubricant**.

(4) As a general rule, **one bearing** can carry both radial and axial loads at the same time.

(5) May be used in either high or low temperature applications.

(6) **Bearing rigidity** can be improved by **preloading**.

Construction, classes, and special features of rolling bearings are fully described in the boundary dimensions and bearing numbering system section.

1.3.2 Ball bearings and roller bearings

Table 1.1 gives a comparison of ball bearings and roller bearings.

Table 1.1 Comparison of ball bearings and roller bearings

	Ball bearing	Roller bearing
Contact with raceway	 2a 2b **Point contact** Contact surface is oval when a load is applied.	 ℓ 2b **Linear contact** Contact surface is generally rectangular when a load is applied.
Characteristics	Because of point contact, where there is little rolling resistance, ball bearings are suitable for low torque and high-speed applications. They also have superior acoustic characteristics.	Because of linear contact, rotational torque is higher for roller bearings than for ball bearings, but rigidity is also higher.
Load capacity	Load capacity is lower for ball bearings, but radial bearings are capable of bearing loads in both the radial and axial direction.	Load capacity is higher for rolling bearings. Cylindrical roller bearings equipped with a lip can bear slight axial loads. Combining tapered roller bearings in pairs enables the bearings to bear an axial load in both directions.

Classification and Characteristics of Rolling Bearings NTN

Commentary

1.3.3 Contact angle and bearing type

A contact angle is an angle made by a line that connects the contact point of the inner ring, rolling element, and outer ring in the radial direction when a load is applied on the bearing (**Fig. 1.3**).

Bearings with a **contact angle of 45° or less** have a much greater radial load capacity and are classed as **radial bearings**; whereas bearings which have a contact angle over 45° have a greater axial load capacity and are classed as **thrust bearings**. There are also bearings classed as complex bearings which combine the loading characteristics of both radial and thrust bearings.

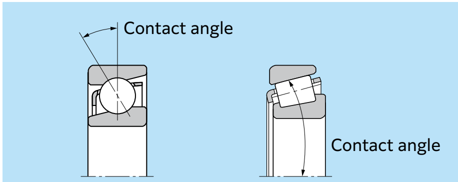

Fig. 1.3 Contact angle

1.3.4 Load acting on bearing

Types of loads applied on rolling bearings are given in **Fig. 1.4**. A moment load is caused by an unbalanced load and misalignment.

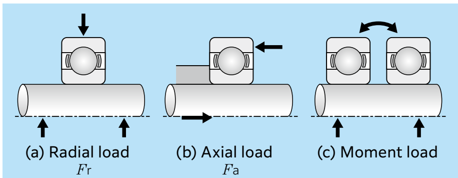

Fig. 1.4 Types of load

1.3.5 Standard bearings and special bearings

The boundary dimensions and shapes of bearings conforming to international standards are interchangeable and can be obtained easily and economically all over the world. It is therefore better to design mechanical equipment that can use standard bearings.

However, depending on the type of machine they are to be used in, and the expected application and function, a non-standard or specially designed bearing may be best. Bearings that are adapted to specific applications, and "unit bearings" which are integrated (built-in) into a machine's components, and other specially designed bearings are also available.

The features of typical standard bearings are as follows:

Deep groove ball bearing

The most common type of bearing, deep groove ball bearings are widely used in a variety of fields. Deep groove ball bearings can include shielded bearings or sealed bearings with grease to make them easier to use.

Deep groove ball bearings also include bearings with a locating snap-ring to facilitate positioning when mounting the outer ring, expansion compensating bearings which absorb dimension variation of the bearing fitting surface due to housing temperature, and TAB bearings that are able to withstand contamination in the lubricating oil.

Table 1.2 Configuration of sealed ball bearings

Type and code	Shielded type	Sealed type		
	Non-contact type ZZ	Non-contact type LLB	Contact type LLU	Low torque type LLH
Structure				
Angular contact ball bearing

The line that unites the point of contact of the inner ring, ball and outer ring runs at a certain angle (contact angle) in the radial direction.

Angular contact ball bearings are generally designed with three contact angles. (Refer to **Table 1.3**)

Angular contact ball bearings can support an axial load, but cannot be used by themselves because of the contact angle. They must instead be used in pairs or in combination. (Refer to **Table 1.5**)

Angular contact ball bearings include double row angular contact ball bearings for which the inner and outer rings are combined as a single unit. (Refer to **Table 1.4**) The contact angle of double row angular contact ball bearings is 25°.

There are also four-point contact bearings that can support an axial load in both directions by themselves. These bearings however require caution because problems such as excessive temperature rise and wear could occur depending on the load conditions.

Classification and Characteristics of Rolling Bearings NTN

Cylindrical roller bearing

Cylindrical roller bearings use rollers for rolling elements, and therefore have a high load capacity. The rollers are guided by the ribs of the inner or outer ring. The inner and outer rings can be separated to facilitate assembly, and both can be fit with a shaft or housing tightly. If there are no ribs, either the inner or the outer ring can move freely in the axial direction. Cylindrical roller bearings are therefore ideal to be used as so-called "free side bearings" that absorb shaft expansion. In the case where there are ribs, the bearing can bear a slight axial load between the end of the rollers and the ribs. Cylindrical roller bearings include the HT type which modifies the shape of the roller end face and ribs for increasing axial load capacity, and the EA type and E type with a special internal design for enhancing radial load capacity. The EA type is standardized for small-diameter sizes.

Table 1.6 shows the basic shapes.

In addition to these, there are cylindrical roller bearings with multiple rows of rollers and the SL type of full complement roller bearings without a cage.

Table 1.6 Types of cylindrical roller bearings

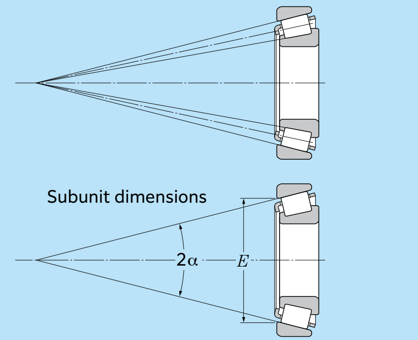
Type code	Type NU Type N	Type NJ Type NF	Type NUP Type NH (NJ HJ)
Design	 Type NU	 Type NJ	 Type NUP
	 Type N	 Type NF	 Type NH

Tapered roller bearing

Tapered roller bearings are designed so the inner/outer ring raceway and apex of the tapered rollers intersect at one point on the bearing centerline. By receiving a combined load from the inner and outer ring, the rollers are pushed against the inner ring rib and are guided by the rib.

Induced force is produced in the axial direction when a radial load is applied, so it must be handled with a pair of bearings. The inner ring with rollers and outer ring come apart, thus facilitating mounting with clearance or preload. Assembled clearance is however hard to manage and requires special attention. Tapered roller bearings are capable of supporting large loads in both the axial and radial directions.

NTN also has a line of case hardened steel bearings designed for longer life (ETA-, etc.). **NTN** tapered roller bearings also include bearings with two and four rows of tapered rollers for extra-heavy loads.



E : Outer ring (cup) nominal small-end diameter
α : Nominal contact angle

Fig. 1.5 Tapered roller bearings

Spherical roller bearing

Equipped with an outer ring with a spherical raceway surface and an inner ring which holds two rows of barrel-shaped rolling elements, **NTN** spherical roller bearings are able to adjust center alignment to handle inclination of the axle or shaft.

There are a variety of spherical roller bearing types that differ according to their internal design.

In addition to cylindrical bore inner rings, spherical roller bearings can be produced with a tapered bore inner ring. The tapered bore bearing can easily be mounted on a shaft by means of an adapter or withdrawal sleeve. The bearing is capable of supporting heavy loads, and is therefore often used for industrial machinery. When a heavy axial load is applied to the bearing, the load on rollers of one row is not applied, and can cause problems. Attention must therefore be paid to operating conditions.

Table 1.7 Types of spherical roller bearings

Type	ULTAGE		B type	C type	213 type
	EA type	EM type			
Structure					
Thrust bearing

There are many types of thrust bearings that differ according to the shape of the rolling element and application.

Allowable rotational speed is generally low and special attention must be paid to lubrication.

In addition to the types shown in **Table 1.8** below, there are various other types of thrust bearings for special applications.

Table 1.8 Types of thrust bearings

Type	Single direction thrust ball bearing	Needle roller thrust bearings
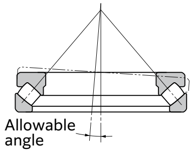
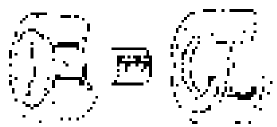
Structure			Thrust cylindrical roller bearing	Thrust self-aligning roller bearing
		


Needle roller bearing

Needle roller bearings use needle rollers as rolling elements. The needle rollers are a maximum of 6 mm in diameter and are 3 to 10 times as long as they are in diameter (JIS B1506 rolling bearings roller). Because the bearings use needle rollers as rolling elements, the cross-section is thin, but they have a high load capacity for their size. Due to the large number of rolling elements, bearings have high rigidity and are ideally suited to oscillating motion.

There are various types of needle roller bearings, and just a few of the most representative types are covered here. For details, see the catalog "**Needle roller bearings (CAT. No. 2300/E)**."

Table 1.9 Main types of needle roller bearings

Type	Needle roller bearing with cage
Structure	
	Solid type needle roller bearings
	
	Drawn cup needle roller bearings
	
	Cam follower Roller follower
	


Bearing unit

A unit comprised of a ball bearing inserted into various types of housings. The housing can be bolted onto machinery and the inner ring can be easily mounted on the shaft with a set screw.

This means the bearing unit can support rotating equipment without a special design to allow for mounting. A variety of standardized housing shapes are available, including pillow block and flange types. The outer diameter of the bearing is spherical just like the inner diameter of the housing, so it is capable of aligning itself on the shaft.

For lubrication, grease is filled inside the bearing, and foreign particles are prevented from entering with a shaft riding seal and slinger shield.

For details, see the catalog "**Bearing unit (CAT. No. 2400/E)**."

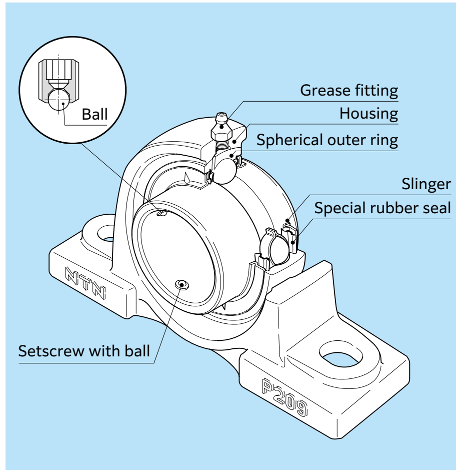


Fig. 1.6 Bearing unit with grease fitting

2. Bearing selection

NTN provides rolling bearings (hereinafter referred to as bearings) of various types and dimensions. When selecting the correct bearing for your application, it is important to consider several factors, and analyze using various means.

2.1 Bearing selection flow chart

An example of the procedure for selecting bearings is shown in the following flow chart. When special consideration is necessary, consult with **NTN** Engineering.

Procedure	Confirmation items
Confirm operating conditions and operating environment	●Function and construction of components to house bearings ●Bearing mounting location ●Bearing load (direction and magnitude) ●Rotational speed ●Vibration and shock load ●Bearing temperature (Ambient temperature/ temperature rise) ●Operating environment (potential for corrosion, degree of contamination, extent of lubrication)
Select bearing type and configuration	●Dimensional limitations (refer to page insert···A-46) ●Bearing load (magnitude,direction,vibration; presence of shock load) (refer to page insert···A-34) ●Rotational speed (refer to page insert···A-106) ●Bearing tolerances (refer to page insert···A-54) ●Rigidity (refer to page insert···A-101) ●Allowable misaligment of inner/outer rings (refer to page insert···A-149) ●Friction torque (refer to page insert···A-110) ●Bearing arrangement (fixed side, floating side) (refer to page insert···A-17) ●Installation and disassembly requirements (refer to page insert···A-150) ●Bearing availability and cost
Select bearing dimensions	●Design life of components to house bearings (refer to page insert···A-27) ●Dynamic/static equivalent load conditions (refer to page insert···A-41) ●Safety factor (refer to page insert···A-31) ●Allowable Speed (refer to page insert···A-106) ●Allowable axial load (refer to page insert···A-31) ●Allowable space (refer to page insert···A-46)
Select bearing tolerances	●Shaft runout tolerances (refer to page insert···A-54) ●Rotational speed (refer to page insert···A-106) ●Torque fluctuation
Select bearing's internal clearance	●Material and shape of shaft and housing (refer to page insert···A-146) ●Bearing Fits (refer to page insert···A-75) ●Temperature differential between inner/outer rings (refer to page insert···A-92) ●Allowable misalignment of inner/outer rings (refer to page insert···A-149) ●Load (magnitude, nature) (refer to page insert···A-34) ●Amount of preload (refer to page insert···A-100) ●Rotational speed (refer to page insert···A-106)
Select cage type and material	●Rotational speed (refer to page insert···A-106) ●Noise level ●Vibration and shock load ●Momentary load ●Lubrication type and method (refer to page insert···A-111)
Select lubricant, lubrication method, sealing method	●Operating temperature (refer to page insert···A-164) ●Rotational speed (refer to page insert···A-106) ●Lubrication type and method (refer to page insert···A-111) ●Sealing method (refer to page insert···A-124) ●Maintenance and inspection (refer to page insert···A-164)
Select any special bearing specifications	●Operating environment (high/low temperature, vacuum, pharmaceutical, etc.) ●Requirement for high reliability
Confirm handling procedures	●Installation-related dimensions (refer to page insert···A-148) ●Installation and disassembly procedures (refer to page insert···A-152)

Selection of bearing type and configuration

(1) Dimensional limitations
There is a wide range of standardized bearing types and dimensions. Typically, for bearing used in machines, it is necessary to select the optimal bearing type and dimension that fits the space allowed in the machine.

(2) Bearing load
There can be various directions, characteristics, and magnitudes of loading that act on bearings. However, in determining the appropriate bearing type, it is also necessary to consider whether the acting load is a radial load only or combined radial and axial load. In addition, it is necessary to determine what bearing type and size is appropriate based on the basic load rating, specified in the bearing dimension table, while considering the magnitude of the load being applied.

(3) Rotational speed
The allowable speed of a bearing will differ depending upon bearing type, size, tolerances, cage type, load, lubricating conditions, and cooling conditions.

The allowable speeds listed in the bearing tables for grease and oil lubrication are for normal tolerance **NTN** bearings. In general, deep groove ball bearings, angular contact ball bearings, and cylindrical roller bearings are most suitable for high speed applications.

(4) Bearing tolerances
The dimensional accuracy and operating tolerances of bearings are regulated by ISO and JIS standards.

For equipment requiring high tolerance shaft runout or high speed operation, bearings with Class 5 tolerance or higher are recommended.

Deep groove ball bearings, angular contact ball bearings, and cylindrical roller bearings are recommended for high rotational tolerances.

(5) Rigidity
Elastic deformation occurs along the contact surfaces of a bearing's rolling elements and raceway surfaces under loading. With certain types of equipment it is necessary to reduce this deformation as much as possible. In general, roller bearings exhibit less elastic deformation than ball bearings. Furthermore, in some cases, bearings are given a load in advance (preloaded) to increase their rigidity. This procedure is commonly applied to deep groove ball bearings, angular contact ball bearings, and tapered roller bearings.

(6) Misalignment of inner and outer rings
Shaft flexure, variations in shaft or housing accuracy, and fitting errors result in a certain degree of misalignment between the bearing's inner and outer rings. In situations where the degree of misalignment is liable to be relatively large, self-aligning ball bearings, spherical roller bearings, bearing units and other bearings with aligning properties are advisable.(Refer to **Fig. 2.1**)

(7) Noise and torque levels
Rolling bearings are manufactured and processed according to high precision standards, and therefore generally produce only slight amounts of noise and torque. For applications requiring particularly low-noise or low-torque operation, deep groove ball bearings and cylindrical roller bearings are most appropriate.

(8) Installation and disassembly
Some applications require frequent disassembly and reassembly to enable periodic inspections and repairs. For such applications, bearings with separable inner/outer rings, such as cylindrical roller bearings, needle roller bearings, and tapered roller bearings are most appropriate. Incorporation of adapter sleeves simplifies the installation and disassembly of self-aligning ball bearings and spherical roller bearings with tapered bores.

5) ○indicates inner ring with tapered bore is possible.

2.3 Selection of bearing arrangement

In general, a shaft is supported by two bearings. A bearing that positions and fixes the shaft in the axial direction is called the "**fixed side bearing**" and a bearing that allows the axial movement is called the "**floating side bearing**." This allows expansion and contraction of the shaft due to temperature variation and absorbs errors in the bearing mounting clearance. Fixing two bearings without providing a floating side bearing applies an excessive load on bearings because of the expansion and contraction or the error, damaging the bearings at an early stage.

The **fixed side bearing** is able to support radial and axial loads. A bearing that can fix axial movement in both directions should therefore be selected. A **floating side bearing** that allows movement in the axial direction while supporting a radial load is desirable. Movement in the axial direction **occurs on the raceway surface** for bearings with separable inner and outer rings such as **cylindrical roller bearings**, and **occurs on the fitting surface** for those which are not separable, such as **deep groove ball bearings**.

When shaft expansion and contraction due to temperature fluctuations is slight, the same type of bearing may be used for both the fixed-side and floating-side bearing.

Table 2.2 (1) shows typical bearing arrangements where the bearing type differs on the fixed side and floating side.**Table 2.2 (2)** shows some common bearing arrangements where no distinction is made between the fixed side and floating side. Vertical shaft bearing arrangements are shown in **Table 2.2 (3)**.

Table 2.2 (1) Bearing arrangement (distinction between fixed and floating-side)

Arrangement		Remarks	Application (Reference)
Fixed side	Floating side		
		1. General arrangement for small machinery. 2. For radial loads, but will also accept axial loads in some degree.	Small pumps, auto-mobile transmissions, etc.
		1. Suitable when mounting error and shaft deflection are minimal or used for high rotational speed application. 2. Even with expansion and contraction of shaft, the floating side moves smoothly.	Medium-sized electric motors, ventilators, etc.
		1. Relatively heavy radial loading and dual direction of axial loading possible. 2. In place of duplex angular contact ball bearings, double-row angular contact ball bearings are also used.	Worm gears, reducers, compressors
		1. Heavy loading capable. 2. Shafting rigidity increased by preloading the two back-to-back fixed bearings. 3. Requires high precision shafts and housings, and minimal fitting errors.	Industrial machinery, large reducers
		1. Allows for shaft deflection and fitting errors. 2. By using an adapter on long shafts without screws or shoulders, bearing mounting and dismounting can be facilitated. 3. Self-aligning ball bearings are used for positioning in the axial direction, and not suitable for applications requiring support of axial load.	Conveyors
		1. Widely used in general industrial machinery with heavy and shock load demands. 2. Allows for shaft deflection and fitting errors in some degree. 3. Accepts radial loads as well as dual direction of axial loads in some degree.	Industrial machinery, large reducers
		1. Accepts radial loads as well as dual direction axial loads in some degree. 2. Suitable if an inner and outer ring tight fit is required.	Industrial machinery, large reducers
		1. Capable of handling large radial and axial loads at high rotational speeds. 2. Maintains clearance between the bearing's outer diameter and housing inner diameter to prevent deep groove ball bearings from receiving radial loads.	Diesel locomotives, carriage axles

Table 2.2 (2) Bearing arrangement (no distinction between fixed and floating-side)

Arrangement	Remarks	Application (Reference)
	1. General arrangement for use in small machines. 2. Preload is sometimes applied by placing a spring on the outer ring side surface or inserting an adjusted shim. (can be floating-side bearings.)	Small electric motors, small reduction gears, etc.
	1. Back-to-back arrangement is preferable to face to face arrangement when moment load applied. 2. Able to support axial and radial loads; suitable for high-speed rotation. 3. Rigidity of shaft can be enhanced by providing preload.	Machine tool spindles, etc.
	1. Capable of supporting heavy loads and impact loads. 2. Suitable if an inner and outer ring tight fit is required. 3. Care must be taken so axial clearance does not become too small during operation.	Construction equipment, mining equipment sheaves, agitators, etc.
 Back-to-back arrangement  Face-to-face arrangement	1. Withstands heavy and shock loads. Wide range application. 2. Shaft rigidity can be enhanced by providing preload, but make sure preload is not excessive. 3. Back-to-back arrangement for moment loads, and face-to-face arrangement to alleviate fitting errors. 4. With face-to-face arrangement, inner ring tight fit is facilitated.	Reduction gears, front and rear axle of automobiles, etc.

Table 2.2 (3) Bearing arrangement (Vertical shaft)

Arrangement	Remarks	Application (Reference)
	1. When a fixing bearing is a duplex angular contact ball bearing, the floating bearing should be a cylindrical roller bearing.	Vertically mounted electric motors, etc.
	1. Most suitable arrangement for very heavy axial loads. 2. Shaft deflection and mounting error can be absorbed by matching the center of the spherical surface with the center of spherical roller thrust bearings.	Crane center shafts, etc.

3. Load rating and life

3.1 Bearing life

Even in bearings operating under normal conditions, the surfaces of the raceway and rolling elements are constantly being subjected to repeated compressive stresses which causes flaking of these surfaces to occur. This flaking is due to material fatigue and will eventually cause bearings to fail.

The effective life of a bearing is usually defined in terms of **the total number of revolutions** a bearing can undergo before **flaking** of either the raceway surface or the rolling element surfaces occurs.

Other causes of bearing failure are often attributed to problems such as seizing, abrasions, cracking, chipping, scuffing, rust, etc. However, these so called "causes" of bearing failure are usually themselves caused by improper installation, insufficient or improper lubrication, faulty sealing or improper bearing selection.

Since the above mentioned "causes" of bearing failure can be avoided by taking proper precautions, and are not simply caused by material fatigue, they are considered separately from the flaking aspect.

3.2 Basic rating life and basic dynamic load rating

A group of seemingly identical bearings when subjected to identical loads and operating conditions will exhibit a wide diversity in their durability. This "life" disparity can be accounted for by the difference in the fatigue of the bearing material itself.

This disparity is considered statistically when calculating bearing life, and **the basic rating life** is defined as follows.

The basic rating life is based on a 90% statistical model which is expressed as the total number of revolutions 90% of the bearings in an identical group of bearings subjected to identical operating conditions will attain or surpass before flaking due to material fatigue. For bearings operating at fixed constant speeds, the basic rating life (90% reliability) is expressed in the total number of hours of operation. Basic dynamic load rating expresses a rolling bearing's capacity to support a dynamic load.

The basic dynamic load rating is **the load which a bearing can theoretically endure for a basic rating life of one million revolutions**. This is expressed as pure radial load for radial bearings and pure axial load for thrust bearings. These are referred to as "**basic dynamic radial load rating (C_r)**" and "**basic dynamic axial load rating (C_a).**"

The basic dynamic load ratings given in the bearing tables of this catalog are for bearings constructed of **NTN** high quality bearing materials and of good manufacturing quality.

The relationship between the basic rating life, the basic dynamic load rating and the dynamic equivalent load is shown in formulas (3.1) and (3.2).

For ball bearings : $L_{10} = \left(\frac{C}{P}\right)^3$ ········· (3.1)

For roller bearings: $L_{10} = \left(\frac{C}{P}\right)^{10/3}$ ····· (3.2)

Where:

L_{10} : Basic rating life 10^6 revolutions
C : Basic dynamic load rating N
Radial bearing C_r
Thrust bearing C_a
P : Dynamic equivalent load N 1)
Radial bearing P_r
Thrust bearing P_a

1) For more details, please refer to the section "4. Bearing load calculation."

The relationship between rotational speed n and speed factor f_n as well as the relationship between life factor f_h and basic rating life L_{10h} are shown in **Table 3.1** and **Fig. 3.1**.

Table 3.1 Bearing basic rating life, life factor, and speed factor

Division	Ball bearing	Roller bearing
Basic rating life L_{10h} h	$\frac{10^6}{60n}\left(\frac{C}{P}\right)^3 = 500 f_h^3$	$\frac{10^6}{60n}\left(\frac{C}{P}\right)^{10/3} = 500 f_h^{10/3}$
Life factor f_h	$f_n \frac{C}{P}$	$f_n \frac{C}{P}$
Speed factor f_n	$\left(\frac{33.3}{n}\right)^{1/3}$	$\left(\frac{33.3}{n}\right)^{3/10}$

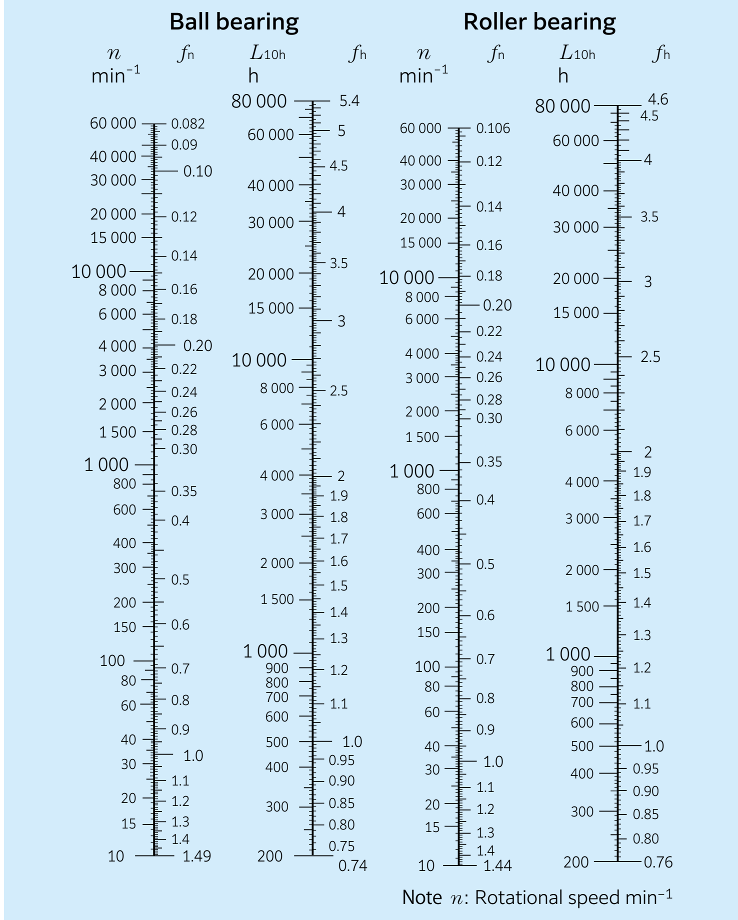

Fig. 3.1 Bearing life rating scale

When several bearings are incorporated in machines or equipment as complete units, all the bearings in the unit are considered as a whole when computing bearing system life (see formula 3.3).

$$L = \frac{1}{\left(\frac{1}{L_1{}^e} + \frac{1}{L_2{}^e} + \cdots \frac{1}{L_n{}^e}\right)^{1/e}} \quad \cdots\cdots\cdots \quad (3.3)$$

Where:

L : Total basic rating life of entire unit, h

$L_1, L_2 \cdots L_n$: Basic rating life of individual bearings 1, 2, ⋯n, h

e : e = 10/9 ⋯⋯⋯ For ball bearings

e = 9/8 ⋯⋯⋯⋯ For roller bearings

When the load conditions vary at regular intervals, the life can be given by formula (3.4).

$$L_m = \left(\frac{\phi_1}{L_1} + \frac{\phi_2}{L_2} + \cdots\cdots \frac{\phi_j}{L_j}\right)^{-1} \cdots\cdots\cdots \quad (3.4)$$

Where:

L_m : Total life of bearing, h

ϕ_j : Frequency of individual load conditions ($\Sigma\phi_j = 1$)

L_j : Life under individual conditions, h

If dynamic equivalent load P and rotational speed n are operating conditions of the bearing, basic rated dynamic load C that satisfies required life of the bearing is determined using **Table 3.1** and formula (3.5). Bearings that satisfy the required C can be selected from the bearing dimensions table provided in the catalog.

$$C = P\frac{f_h}{f_n} \quad \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots \quad (3.5)$$

3.3 Adjusted rating life

The basic bearing rating life can be calculated through the formulas mentioned earlier in Section 3.2. However, in some applications bearing reliability higher than 90% may be required. In addition, bearing life may be enhanced by the use of specialty bearing materials or manufacturing processes. Bearing life is also sometimes affected by operating conditions such as lubrication, temperature and rotational speed.

Basic rating life adjusted to compensate for reliability, special bearing materials and enhancements, and specific operation conditions is called "**adjusted rating life**," and is determined using formula (3.6).

$$L_{na} = a_1 \cdot a_2 \cdot a_3 \cdot L_{10} \cdots\cdots\cdots\cdots\cdots \quad (3.6)$$

Where:

L_{na} : Adjusted rating life in millions of revolutions (10^6)

a_1 : Life adjustment factor for reliability

a_2 : Life adjustment factor for special bearing properties

a_3 : Life adjustment factor for operating conditions

3.3.1 Life adjustment factor for reliability a_1

The value of **life adjustment factor for reliability a_1** is provided in **Table 3.2** for reliability of 90% or greater.

3.3.2 Life adjustment factor for special bearing properties a_2

Bearing characteristics concerning life vary according to bearing material, quality of material and if using a special manufacturing process. In this case, life is adjusted using **life adjustment factor for special bearing properties a_2**.

The basic dynamic load ratings listed in the catalog are based on **NTN**'s standard material and the adjustment factor used is a_2 = 1. However, an adjustment factor of a_2 other than 1 may be used for bearings with specially enhanced materials and manufacturing methods.

[NOTE: a_2 < 1 may occur for temperature stabilization]

a_2 > 1 may be used for bearings with specially improved materials and manufacturing methods.

Bearings made of high carbon chrome bearing steel, conventionally heat treated, may experience dimensional changes during operation if used at high temperatures for extended periods of time. Temperature stabilization treatment (**TS treatment**) can be used to provide increased dimensional stability of bearing materials at high operational temperatures. However, the dimensional stabilization treatment results in a lower overall hardness of heat treated bearing materials; therefore, the life is adjusted by multiplying by life adjustment factor for special bearing properties a_2 given in **Table 3.3**.

For further clarification please consult with **NTN** Engineering.

Table 3.2 Life adjustment factor for reliability a_1

Reliability %	L_n	Life adjustment factor for reliability a_1
90	L_{10}	1.00
95	L_5	0.64
96	L_4	0.55
97	L_3	0.47
98	L_2	0.37
99	L_1	0.25
99.2	$L_{0.8}$	0.22
99.4	$L_{0.6}$	0.19
99.6	$L_{0.4}$	0.16
99.8	$L_{0.2}$	0.12
99.9	$L_{0.1}$	0.093
99.92	$L_{0.08}$	0.087
99.94	$L_{0.06}$	0.080
99.95	$L_{0.05}$	0.077

Table 3.3 Treatment for dimensional stabilization

Code	Max. operating temperature °C	Life adjustment factor for special bearing properties a_2
TS2	160	1.00
TS3	200	0.73
TS4	250	0.48

Please consult **NTN** Engineering for life adjustment factor for special bearing properties (a_2) when using dimensional stabilization treatment combined with any specialty bearing material.

3.3.3 Life adjustment factor for operating conditions a_3

Life adjustment factor for operating conditions a_3 is used to compensate for when lubrication condition worsens due to a rise in temperature or rotational speed, lubricant deteriorates or it becomes contaminated with foreign matter.

Generally speaking, when lubricating conditions are satisfactory, the a_3 factor has a value of 1.0; and when lubricating conditions are exceptionally favorable, and all other operating conditions are normal, a_3 can have a value greater than 1.0. The factor a_3 may be less than 1.0 due to the following cases:

- Dynamic viscosity of lubrication is too low for bearing operating temperature (13 mm²/s or less for ball bearings, 20 mm²/s or less for roller bearings as a standard)
- Rotational speed is particularly low (when the product of pitch diameter D_{pw} mm and rotational speed n min^{-1} is $D_{pw} \cdot n$ < 10 000)
- Lubricant contaminated with foreign matter or moisture

If using a special operating condition, consult with **NTN** Engineering.

The operating life may be also shortened by misalignment and operating clearance but these operating conditions are not accounted for by the a_3 factor. (See sections "3.7 Misalignment angle (installation error) and life" and "3.8 Clearance and life.")

Even if a_2 > 1 is used for specialty bearings made of enhanced materials or produced by special manufacturing methods, a_2 x a_3 < 1 is used if lubricating conditions are not favorable.

When an excessively heavy load is applied, harmful plastic distortion may result at the contact surfaces between the rolling elements and raceways. The formulae for determining basic rating life (3.1, 3.2, and 3.6) do not apply if P_r exceeds either C_{0r} (basic static load rating) or 0.5 C_r for radial bearings, or if P_a exceeds 0.5 C_a for thrust bearings.

3.4 Modified rating life

3.4.1 Background

Adjusted rating life L_{na} of bearings is as shown in formula (3.6). System conditions corresponding to a_2 and a_3 are considered independently in that approach. However, it is desirable to consider the integrated system as a whole, resulting in adoption of ISO281:2007. This approach considers **life modification factor a_{ISO}**, which provides a more practical method to consider the influence of lubrication, contamination and fatigue load on bearing life. Based on these decisions in ISO 281, JIS B 1518 was similarly revised in 2013.

Modified rating life L_{nm} using life modification factor a_{ISO} can be obtained by formula (3.7).

$$L_{nm} = a_1 \cdot a_{ISO} \cdot L_{10} \quad \cdots\cdots\cdots\cdots (3.7)$$

3.4.2 Life modification factor a_{ISO}

The life modification factor, a_{ISO}, is a function of lubrication, contamination, material characteristics, and load as shown in formula 3.8.

$$a_{ISO} = f\left(\frac{e_c C_u}{P}, \kappa\right) \quad \cdots\cdots\cdots\cdots (3.8)$$

Where:

C_u : Fatigue load limit

The fatigue load limit is a load applied on bearings that results in the fatigue limit stress at the maximum loaded contact within the raceway. This depends on the bearing type, internal specifications, quality, and material strength. In ISO 281:2007, 1.5GPa is recommended as contact stress corresponding to C_u for the bearings made of commonly used high quality material and good manufacturing quality. The fatigue load limit values with respect to the **NTN** bearing numbers are specified in each specification table.

e_c : Contamination factor

The presence of hard particle contaminants in the lubricant (oil) have the potential to form indentations on the raceway surface, resulting in surface initiated damage and in reduction in bearing life. Contamination factor e_c considers this and depends on the level of contamination, bearing size, and lubricant viscosity (oil film thickness). As shown in **Table 3.4**, approximate values are determined by the bearing size (may be substituted by rolling element pitch diameter D_{pw}, average bearing diameter $(d + D)/2$), filtration and seal structures (including presence of pre-washing).

κ : Viscosity ratio

Bearings are used on the assumption that the rolling contact surface is separated by the lubricant. However, when the viscosity of the lubricant is low, separation becomes insufficient and metal to metal contact occurs, causing surface initiated damage. Viscosity ratio κ considers this effect and is represented by formula (3.9) by the ratio of dynamic viscosity ν in use with respect to reference dynamic viscosity ν_1 of the lubricant.

$$\kappa = \nu / \nu_1 \quad \cdots\cdots\cdots\cdots (3.9)$$

Reference dynamic viscosity ν_1 depends on rotation speed n and size (D_{pw}), and can be obtained by **Fig. 3.2** or formula (3.10) and formula (3.11).

Table 3.4 Value of contamination factor e_c

Level of contamination	e_c D_{pw}< 100mm	e_c D_{pw}≧ 100mm
Extreme cleanliness Particle size of the order of lubricant film thickness; laboratory conditions	1	1
High cleanliness Oil filtered through extremely fine filter; conditions typical of bearing greased for life and sealed	0.8~0.6	0.9~0.8
Normal cleanliness Oil filtered through fine filter; conditions typical of bearings greased for life and shielded	0.6~0.5	0.8~0.6
Slight contamination Slight contamination in lubricant	0.5~0.3	0.6~0.4
Typical contamination Conditions typical of bearings without integral seals; course filtering; wear particles and ingress from surroundings	0.3~0.1	0.4~0.2
Severe contamination Bearing environment heavily contaminated and bearing arrangement with inadequate sealing	0.1~0	0.1~0
Very severe contamination	0	0

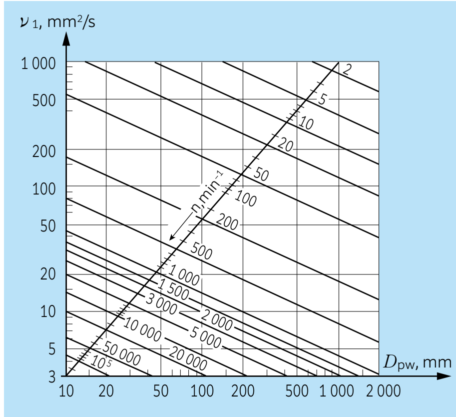

Fig. 3.2 Diagram for reference dynamic viscosity ν_1

In the case of $n < 1\,000\text{min}^{-1}$,

$$\nu_1 = 45\,000\, n^{-0.83} D_{pw}^{-0.5} \quad \cdots\cdots (3.10)$$

In the case of $n \geqq 1\,000\text{min}^{-1}$,

$$\nu_1 = 4\,500\, n^{-0.5} D_{pw}^{-0.5} \quad \cdots\cdots (3.11)$$

Fig. 3.3 shows the relationship among C_u/P, e_c, κ and, a_{ISO} of radial ball bearings. Using the figure has the following restrictions:

1) For practical use, the life modification factor shall be limited $a_{ISO} \leq 50$.
2) In the case of $\kappa > 4$, $\kappa = 4$ shall be assumed. The same approach does not apply in the case of $\kappa < 0.1$.

Diagrams for radial roller bearings, thrust ball bearings, and thrust roller bearing have also been presented (**Figs. 3.4 to 3.6**). The diagrams can be applied regardless of lubrication types; however, for grease lubrication, special additives, and special rotating behaviors, consult with **NTN** Engineering.

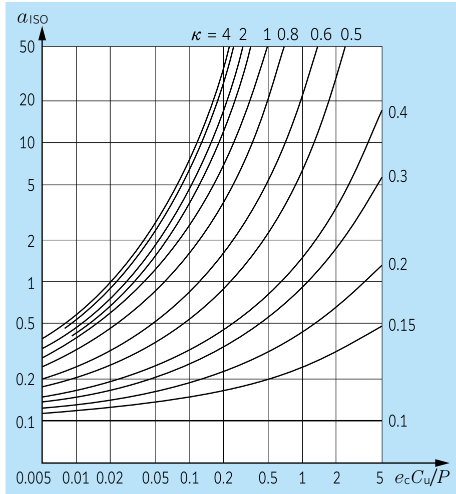

Fig. 3.3 Life modification factor a_{ISO} (radial ball bearing)

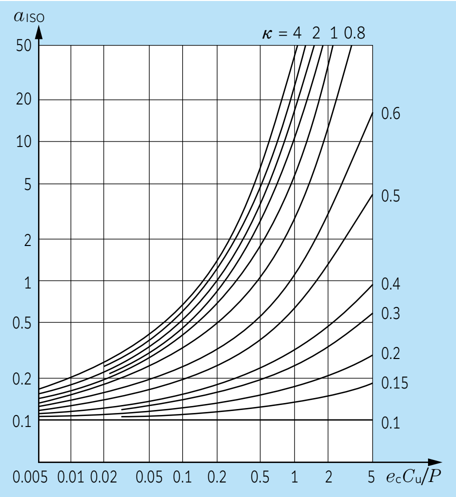

Fig. 3.4 Life modification factor a_{ISO} (radial roller bearing)

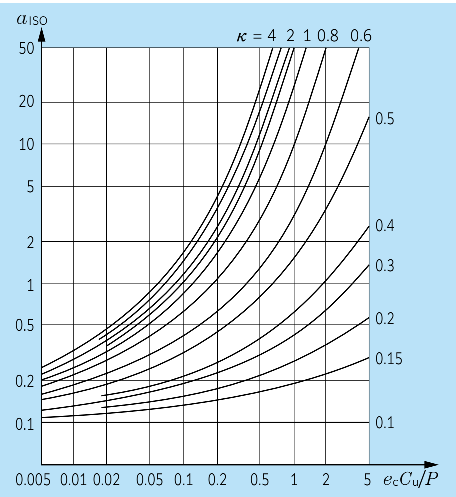

Fig. 3.5 Life modification factor a_{ISO} (thrust ball bearing)

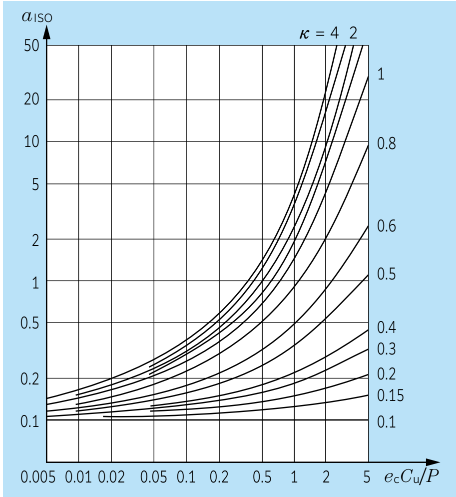

Fig. 3.6 Life modification factor a_{ISO} (thrust roller bearing)

3.4.3 Applicable bearings of modified rating life

Fatigue load limit C_u used for the calculation of life modification factor a_{ISO} depends on the bearing materials. **NTN** bearings that have undergone standard through hardening (immersion quenching) and is made of bearing steel, the fatigue load limit value with respect to each bearing number is specified in each dimension table, and a_{ISO} can be applied.

3.5 Machine applications and requisite life

When selecting a bearing, it is essential that the requisite life of the bearing be established in relation to the operating conditions. The requisite life of the bearing is usually determined by the type of machine in which the bearing will be used, and duration of service and operational reliability requirements. A general guide to these requisite life criteria is shown in **Table 3.5**.

When determining bearing size, the fatigue life of the bearing is an important factor; however, besides bearing life, the strength and rigidity of the shaft and housing must also be taken into consideration.

Table 3.5 Machine application and requisite life (reference)

Service classification	Machine application and requisite life L_{10h} ×10³ hours				
	Up to 4	4 to 12	12 to 30	30 to 60	60 or more
Machines used for short periods or used only occasionally	Household appliances Electric hand tools	Farm machinery Office equipment			
Short period or intermittent use, but with high reliability requirements	Medical appliances Measuring instruments	Home air-conditioning motor Construction equipment Elevators Cranes	Crane (sheaves)		
Machines not in constant use, but used for long periods	Automobiles Two-wheeled vehicles	Small motors Buses/trucks General gear drives Woodworking machines	Machine spindles Industrial motors Crushers Vibrating screens	Main gear drives Rubber/plastic Calender rolls Printing machines	
Machines in constant use over 8 hours a day		Roll neck of steel mill Escalators Conveyors Centrifuges	Railway vehicle axles Air conditioners Large motors Compressor pumps	Locomotive axles Traction motors Mine hoists Pressed flywheels	Papermaking machines Propulsion equipment for marine vessels
24 hour continuous operation, non-interruptible					Water supply equipment Mine drain pumps/ventilators Power generating equipment

3.6 Weibull distribution and life adjustment factor for reliability

As described in "3.2 Basic rating life and basic dynamic load rating," a group of seemingly identical bearings when subjected to an identical load and operating conditions may exhibit a wide variation in their durability. In general, this variation is known to follow the "Weibull distribution," and the basic theory is constructed on the premise that the bearing operating life follows the Weibull distribution also regarding the life calculation formulae (3.1) and (3.2) and the calculation formula of the basic dynamic load rating C.

As an index representing the variation of the Weibull distribution, there is a coefficient called a Weibull slope. A value 10/9 for ball bearings and 9/8 for roller bearings are given in the basic life calculation theory of ISO and JIS. According to this, for example, for a deep groove ball bearing, a difference of 5 times or more is generated between the L_{10} life of 90% reliability and the L_{50} life of 50% reliability.

In some applications where a bearing is used, a life study with reliability exceeding 90% may be required, and in such a case, a life adjustment factor for reliability a_1 is used. In the latest ISO (ISO 281:2007) and JIS (JIS B 1518:2013), a_1 values were updated based on measured test data (see **Fig. 7**). **Table 3.2** shows the latest a_1 values after review.

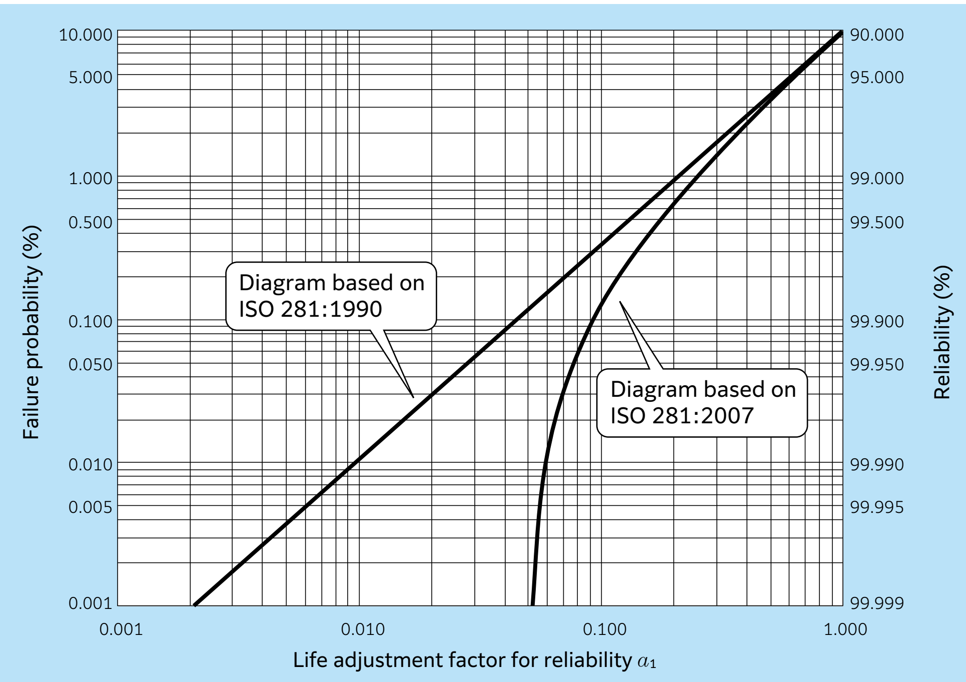

Fig. 7 Life adjustment factor for reliability a_1

3.7 Misalignment angle (installation error) and life

A lack of accuracy and/or rigidity of the shaft or housing can cause misalignment between the bearing inner and outer rings similar to an externally applied moment load.

The bearing operating life calculation in the case of receiving a moment load cannot be obtained by the commonly used $L = (C_r / P_r)^{P}$, which is generally used, and it is necessary to obtain it considering the internal design, clearance, etc. of each bearing.

Since the life decrease rate differs depending on the internal clearance, the load condition, and the internal design, it is necessary to calculate the ratio under individual conditions, and the rate cannot be given as a factor in general.

Fig. 3.8 and **Fig. 3.9** show the results of detailed calculation of the relationship between the misalignment angle (installation error) and the life of a deep groove ball bearing and a cylindrical roller bearing.

See **Table 14.6** in section "14. Shaft and housing design" for the rough standard of allowable misalignment and allowable misalignment of each bearing type.

For further clarification please consult with **NTN** Engineering.

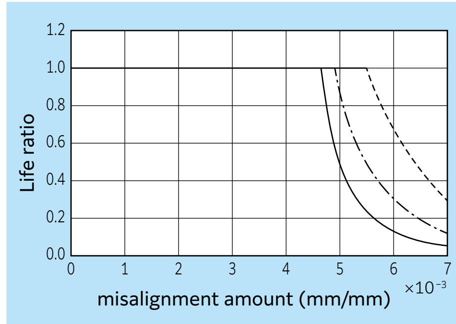

Fig. 3.8 Misalignment angle and life ratio of deep groove ball bearing

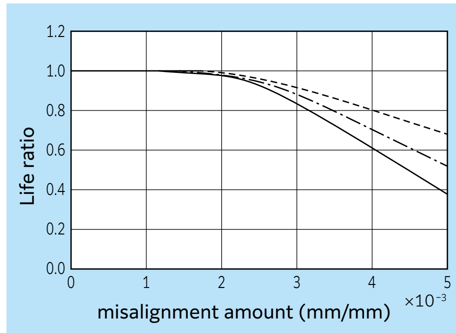

Fig. 3.9 Misalignment angle and life ratio of cylindrical roller bearing

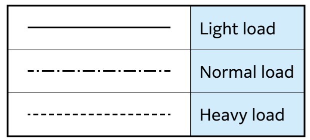

3.8 Clearance and life

It is very difficult to accurately determine what the clearance of a rolling bearing should be in a normal operating state.

When a bearing is subjected to a simple load and full rotation slight clearance is preferable. However, too large of a clearance can cause life deterioration and vibration. In contrast, a negative clearance (preload) can extend the operating life and prevent shaft runout. However, too large of a preload increases friction, temperature rise, lubrication degradation and can cause seizures in extreme cases.

As a general guideline a target of zero operating clearance should be acceptable.

1) Clearance and rolling element load W

(1) In the case of bearing clearance larger than 0 [**Fig. 3.11**], load distribution $\varepsilon < 0.5$ holds. The maximum rolling element load becomes larger than when the bearing clearance is zero [**Fig. 3.10**].

[Load factor ε and conceptual diagram]

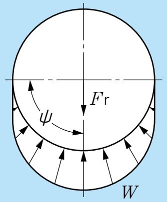

Fig.3.10
$\varepsilon = 0.5$ $\psi = \pm 90°$
Radial clearance 0

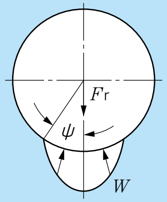

Fig.3.11
$0 < \varepsilon < 0.5$ $0 < \psi < 90°$
There is radial clearance

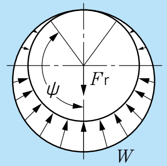

Fig.3.12
$0.5 < \varepsilon < 1$
$90° < \psi < 180°$
Radial preload state,
or large axial load

(2) **Fig. 3.13** shows an ideal graph in which operating in a slightly preloaded condition results in maximum bearing life.

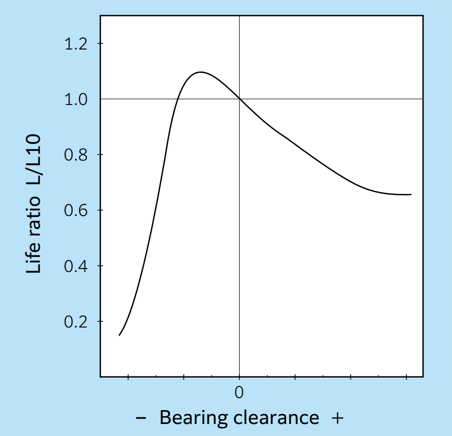

Fig. 3.13 Bearing clearance and life ratio

3.9 Basic static load rating

It has been found through experience that a permanent deformation of 0.0001 times the diameter of the rolling element, occurring at the most heavily stressed contact point between the raceway and the rolling elements, can be tolerated without any subsequent impariment of bearing operation.

Testing indicates the above level of permanent deformation corresponds to a calculated contact stress as shown below. The basic static load rating is defined as the static applied load which results in such a contact stress at the center of the contact patch between the raceway and the rolling element receiving the maximum load.

Roller bearings: 4 000 MPa
Ball bearings
(excluding self-aligning ball bearings): 4 200 MPa
Self-aligning ball bearings: 4 600 MPa

Referred to as "**basic static radial load rating**" for radial bearings and "**basic static axial load rating**" for thrust bearings, the basic static load rating is expressed as C_{0r} or C_{0a} respectively and is provided in the bearing dimensions table.

3.10 Allowable static equivalent load

Generally the static equivalent load which can be permitted (See page A-41) is limited by the basic static load rating as stated in Section 3.9. However, depending on application requirements regarding friction and smooth operation, these limits may be greater or lesser than the basic static load rating.

This is generally determined by taking the safety factor S_0 given in formula (3.12) and guidelines of **Table 3.6** into account.

$$S_0 = C_0 / P_0 \quad \cdots\cdots\cdots (3.12)$$

Where:
S_0: Safety factor
C_0: Basic static load rating, N
Radial bearing: C_{0r}
Thrust bearing: C_{0a}
P_0: Static equivalent load, N
Radial bearing: P_{0r}
Thrust bearing: P_{0a}

Table 3.6 Minimum safety factor values S_0

Operating conditions	Ball bearing	Roller bearing
Applications that require quiet rotation	2	3
Applications subjected to impact loads	1.5	3
Normal rotation applications	1	1.5

Note: 1. For spherical thrust roller bearings, min. S_0 value = 4.
2. For shell needle roller bearings, min. S_0 value = 3. However, for premium shells (see **the catalog: CAT. No. 3029/JE**), min. S_0 value = 2.
3. When vibration and/or shock loads are present, a load factor based on the shock load needs to be included in the P_0 max value.
4. If a large axial load is applied to deep groove ball bearings or angular ball bearings, the contact ellipse may exceed the raceway surface. For more information, please contact **NTN** Engineering.
5. When an AS type raceway washer is used in a thrust bearing, min. S_0 value = 3.

3.11 Allowable axial load

Radial bearings can also receive axial loads, but load is limited depending on the bearing type.

(1) Ball bearing

When an axial load acts on ball bearings, such as deep groove ball bearings and angular contact ball bearings, the contact angle changes with the load. The contact ellipse formed between the ball and the raceway surface may protrude from the groove when the load exceeds the allowable range.

This contact surface has an elliptical shape in which 1/2 the major diameter becomes a as shown in **Fig. 3.14**. The maximum allowable axial load is the maximum applied load in which the contact ellipse does not exceed the shoulder of the raceway groove. It is important to note that the axial load must result in P_{max} < 4200 MPa even if the contact ellipse does not exceed the shoulder of the groove. The allowable axial load differs depending on the bearing internal clearance, groove curvature, and groove shoulder dimension.

When a combination radial and axial load is applied, verify truncation does not occur at the maximum loaded rolling element.

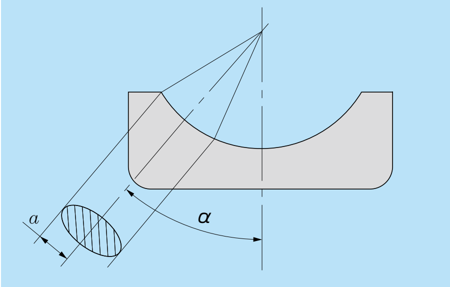

Fig. 3.14 Contact ellipse

(2) Tapered roller bearing (Fig. 3.15)

A tapered roller bearing supports axial load at the raceway surface and at the interface between the roller end face and large end rib. Therefore, the bearing can receive a larger axial force by increasing the contact angle α. However, there are different limits depending on the rotational speed and lubrication conditions because sliding contact occurs between the roller large end face and the large end rib inside face. Generally, the PV value, which is obtained by multiplying the sliding speed to the sliding surface pressure, is checked and calculated by a computer.

For further clarification please consult with **NTN** Engineering.

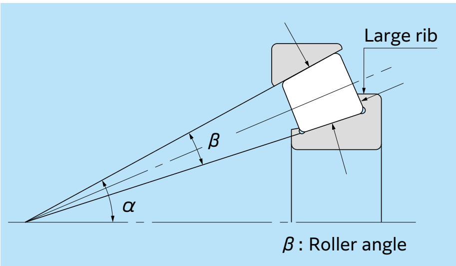

Fig. 3.15 Tapered roller bearings

(3) Cylindrical roller bearings

Cylindrical roller bearings with ribs on the inner and outer rings are capable of simultaneously supporting a certain degree of radial and axial loads. Unlike basic dynamic load ratings which are based on rolling fatigue, allowable axial load is determined by heat generated at the sliding surface between the ends of the rollers and rib which may cause wear and/or seizure. Based on testing and experience, allowable axial load can be estimated using formula (3.13).

$$P_t = k \cdot d^2 \cdot P_z \quad \cdots\cdots (3.13)$$

Where:

P_t : Allowable axial load when rotating N

k : Factor determined by internal design of bearing (see **Table 3.7**)

d : Bearing bore mm

P_z : Allowable surface pressure of rib MPa (see **Fig. 3.16**)

If the axial load is greater than the radial load, the rollers will not rotate properly. The allowable axial load therefore must not exceed the value for $F_{a\,max}$ given in **Table 3.7**.

The following are also important to operate the bearing smoothly under an axial load:

1) Do not make the internal radial clearance any larger than necessary because it may affect life and abrasion between the raceway surface and the roller.
2) Use lubricant with an extreme pressure additive to suppress heat generation, seizure, and abrasion between the roller end surface and the rib.
3) Make the shoulder of the housing and shaft high enough for the rib of the bearing to prevent it from being damaged.
4) If the bearing is to support an extreme axial load, mounting precision should be improved and the bearing should be rotated slowly before actual use.

If large cylindrical roller bearings (bore of 300 mm or more) are to support an axial load or moment load simultaneously, please contact **NTN** Engineering.

NTN Engineering also offers cylindrical roller bearings for high axial loads (HT type). For details, please contact **NTN** Engineering.

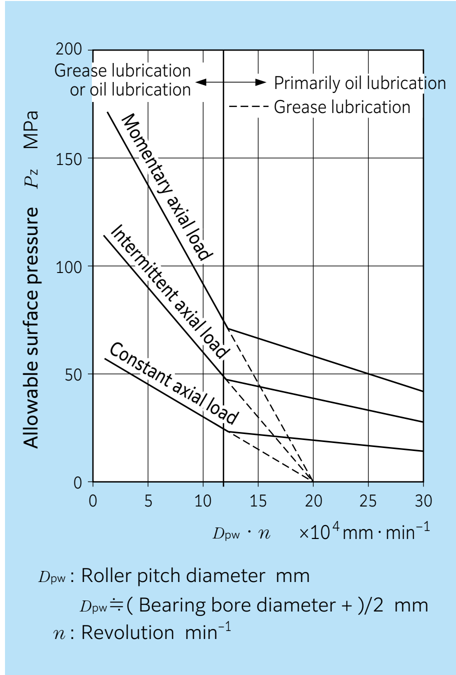

Fig. 3.16 Allowable surface pressure of rib

Table 3.7 Factor k values and allowable axial load ($F_{a\,max}$)

Bearing series	k	$F_{a\,max}$
NJ, NUP10 NJ, NUP, NF, NH2, NJ, NUP, NH22	0.040	$0.4F_r$
NJ, NUP, NF, NH3, NJ, NUP, NH23	0.065	$0.4F_r$
NJ, NUP, NH2EA (E) NJ, NUP, NH22EA (E)	0.050	$0.4F_r$
NJ, NUP, NH3EA (E) NJ, NUP, NH23EA (E)	0.080	$0.4F_r$
NJ, NUP, NH4,	0.100	$0.4F_r$

SL04-50	0.044	$0.2F_r$

Note: Type EA and type E have the same value.

3.12 Review of basic dynamic load ratings

As a result of continuous improvement related to material cleanliness, and production techniques, years of in-house durability testing has confirmed **NTN** bearings produced today have a longer operating life compared with past products. Based on this bearing life test data, the basic dynamic load ratings of ball and roller bearings were reviewed and updated to more accurately reflect true bearing performance.

The basic dynamic load ratings for many **NTN** products have been formally increased and can be found in the dimensional tables for each bearing type within this catalog.

* Some bearings use the same basic dynamic load rating as conventional products.

3.13 Bearing life calculation tool

The basic rating life of bearings can be calculated using the bearing technical calculation tool on the **NTN** website (https://www.ntnglobal.com/tool/calc/).

4. Bearing load calculation

To compute bearing loads, the forces which act on the shaft being supported by the bearing must be determined. Loads which act on the shaft and its related parts include weight of the rotating components, load produced when the machine performs work, and load produced by transmission of dynamic force. These can be mathematically calculated, but calculation is difficult in many cases.

A method of calculating loads that act upon shafts that convey dynamic force, which is the primary application of bearings, is provided herein.

4.1 Load acting on shafts

4.1.1 Load factor

There are many instances where the actual operational shaft load is much greater than the theoretically calculated load, due to shock. This actual shaft load can be estimated by using formula (4.1).

$$K = f_w \cdot K_c \cdots\cdots (4.1)$$

Where:

K : Actual shaft load N
f_w : Load factor (**Table 4.1**)
K_c : Theoretically calculated value N

Table 4.1 Load factor f_w

Amount of shock	f_w	Machine application examples
Very little or no shock	1.0 to 1.2	Electric machines, machine tools, measuring instruments.
Light shock	1.2 to 1.5	Railway vehicles, automobiles, rolling mills, metal working machines, paper making machines, printing machines, aircraft, textile machines, electrical units, office machines.
Heavy shock	1.5 to 3.0	Crushers, agricultural equipment, construction equipment, cranes.

4.1.2 Gear load

The loads operating on gears can be divided into three main types according to the direction in which the load is applied; i.e. tangential (K_t), radial (K_s), and axial (K_a). The magnitude and direction of these loads differ according to the types of gears involved. The following refers to the calculation methods of loads acting on four types of gears.

(1) Loads acting on parallel shaft gears

The forces acting on spur gears and helical gears are depicted in **Fig. 4.1** to **Fig. 4.3**.

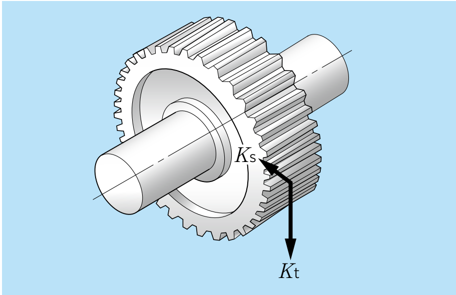

Fig. 4.1 Spur gear loads

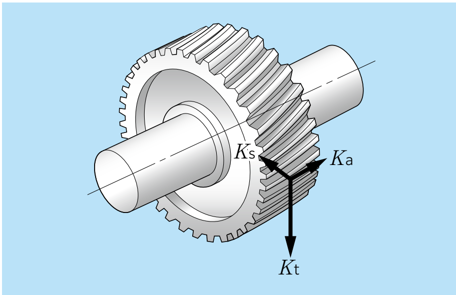

Fig. 4.2 Helical gear loads

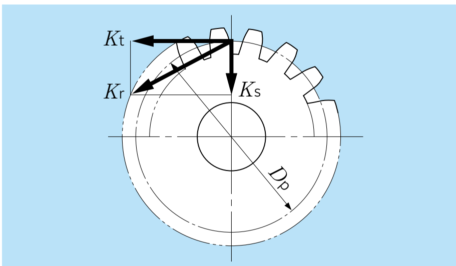

Fig. 4.3 Radial resultant forces

Loads acting on gears are obtained from formulas (4.2) to (4.6).

Equation 4.2 describes the gear load in the tangential direction when the shaft input torque is known

$$K_t = \frac{2T}{D_p} \cdots\cdots (4.2)$$

Equation 4.3 describes the gear load in the tangential direction when the transmitted power is known

$$K_t = \frac{19.1 \times 10^6 \cdot H}{D_p \cdot n} \cdots\cdots (4.3)$$

$$K_s = K_t \cdot \tan\alpha \text{ (Spur gear)} \cdots\cdots (4.4a)$$

$$= K_t \cdot \frac{\tan\alpha}{\cos\beta} \text{ (Helical gear)} \cdots\cdots (4.4b)$$

$$K_r = \sqrt{K_t^2 + K_s^2} \cdots\cdots (4.5)$$

$$K_a = K_t \cdot \tan\beta \text{ (Helical gear)} \cdots\cdots (4.6)$$

Where:

K_t : Tangential gear load (tangential force), N
K_s : Radial gear load (separating force), N
K_r : Right angle shaft load (resultant force of tangential force and separating force), N
K_a : Parallel load on shaft, N
T : Input torque, N · mm
H : Transmitted force, kW
n : Rotational speed min^{-1}
D_p : Gear pitch circle diameter, mm
α : Gear pressure angle, deg
β : Helix angle, deg

Because the actual gear load also contains vibrations and shock loads as well, the theoretical load obtained by the above formula can also be adjusted by the gear factor f_z as shown in **Table 4.2**.

Table 4.2 Gear factor f_z

Gear type	f_z
Precision ground gears (Pitch and tooth profile errors of less than 0.02mm)	1.05 to 1.1
Ordinary machined gears (Pitch and tooth profile errors of less than 0.1mm)	1.1 to 1.3

(2) Loads acting on cross shafts

Gear loads acting on straight tooth bevel gears and spiral bevel gears on cross shafts are shown in **Figs. 4.4** and **4.5**. The calculation methods for these gear loads are shown in **Table 4.3**.

Herein, to calculate gear loads for straight bevel gears, the helix angle β = 0.

The symbols and units used in **Table 4.3** are as follows:

K_t : Tangential gear load (tangential force), N
K_s : Radial gear load (separating force), N
K_a : Parallel shaft load (axial load), N
H : Transmitted power, kW
n : Rotational speed min^{-1}
D_{pm} : Mean pitch circle diameter, mm
α : Gear pressure angle, deg
β : Helix angle, deg
δ : Pitch cone angle, deg

Because the two shafts intersect, pinions and gears have the relationship of formula (4.7) and formula (4.8).

$$K_{sp} = K_{ag} \cdots\cdots (4.7)$$

$$K_{ap} = K_{sg} \cdots\cdots (4.8)$$

Where:

K_{sp} , K_{sg} : Pinion and Gear separating force, N
K_{ap} , K_{ag} : Pinion and Gear axial load, N

For spiral bevel gears, the direction of the load varies depending on the direction of the helix angle, the direction of rotation, and which side is the driving side or the driven side. The directions for the separating force (K_s) and axial load (K_a) shown in **Fig. 4.5** are positive directions. The direction of rotation and the helix angle direction are defined as viewed from the large end of the gear. The gear rotation direction in **Fig. 4.5** is assumed to be clockwise (right).

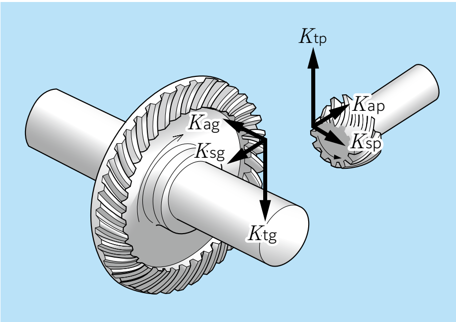

Fig. 4.4 Loads on bevel gears

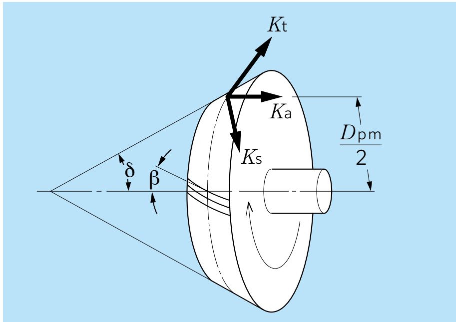

Fig. 4.5 Bevel gear diagram

Table 4.3 Loads acting on bevel gears

Types of load	Rotation direction	Clockwise	Counter clockwise	Clockwise	Counter clockwise
	Helix direction	Right	Left	Left	Right
Tangential load (tangential force) K_t		$K_t=\frac{19.1\times10^6\cdot H}{D_{pm}\cdot n}$			
Radial load (separation force) K_s	Driving side	$K_s=K_t\left[\tan\alpha\frac{\cos\delta}{\cos\beta}+\tan\beta\sin\delta\right]$		$K_s=K_t\left[\tan\alpha\frac{\cos\delta}{\cos\beta}-\tan\beta\sin\delta\right]$	
	Driven side	$K_s=K_t\left[\tan\alpha\frac{\cos\delta}{\cos\beta}-\tan\beta\sin\delta\right]$		$K_s=K_t\left[\tan\alpha\frac{\cos\delta}{\cos\beta}+\tan\beta\sin\delta\right]$	
Parallel load on gear shaft (axial load) K_a	Driving side	$K_a=K_t\left[\tan\alpha\frac{\sin\delta}{\cos\beta}-\tan\beta\cos\delta\right]$		$K_a=K_t\left[\tan\alpha\frac{\sin\delta}{\cos\beta}+\tan\beta\cos\delta\right]$	
	Driven side	$K_a=K_t\left[\tan\alpha\frac{\sin\delta}{\cos\beta}+\tan\beta\cos\delta\right]$		$K_a=K_t\left[\tan\alpha\frac{\sin\delta}{\cos\beta}-\tan\beta\cos\delta\right]$	

(3) Load acting on hypoid gears

A hypoid gear is a spiral bevel gear that transmits power by offset shafts. **Fig. 4.6** shows the load acting on a hypoid gear, and **Table 4.4** shows the calculation method.

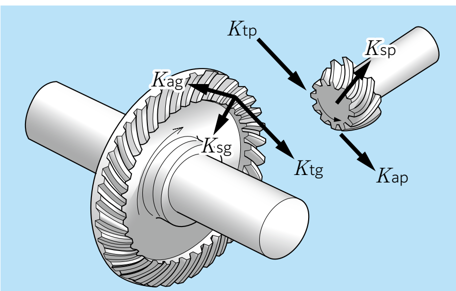

Fig. 4.6

Where:

K_t : Tangential gear load (tangential force), N
K_s : Radial gear load (separating force), N
K_a : Parallel shaft load (axial load), N
H : Transmitted force, kW
n : Rotational speed min^{-1}
D_p : Gear mean pitch circle diameter, mm
α : Gear pressure angle, deg
β : Helix angle, deg
δ_1 : Tooth tip cone angle, deg
δ_2 : Tooth bottom cone angle, deg
*The driving shaft has a subscript p, and the driven shaft has a subscript g.

Table 4.4 Formula of load acting on hypoid gears

Types of load	Rotation direction	Clockwise	Counter clockwise	Clockwise	Counter clockwise
	Helix direction	Right	Left	Left	Right

$$K_{ag}=\frac{K_{tg}}{\cos\beta_g}(\tan\alpha_g\sin\delta_{g2}-\sin\beta_g\cos\delta_{g2})\cdots (4.18)$$

(4) Load acting on worm gears

A worm gear is a gear made by combining a worm (screw gear) and a worm wheel (helical gear). The gear direction differs depending on the rotation direction and the screw direction (right screw, left screw) of the worm shaft. **Fig. 4.8** shows the direction of loads acting on the gear, and **Table 4.5** shows the calculation method of the loads.

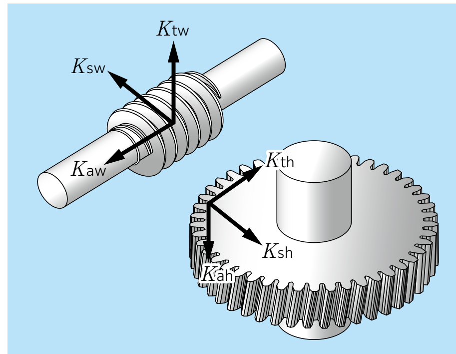

Fig. 4.7 Worm gears

K_t : Tangential gear load (tangential force), N
K_s : Radial gear load (separating force), N
K_a : Parallel shaft load (axial load), N
H : Transmitted force, kW
n : Rotational speed min^{-1}
D_p : Gear mean pitch circle diameter, mm
α : Gear pressure angle, deg
γ : Worm lead angle, deg
*The worm shaft has a subscript w, and the worm gear has a subscript h.

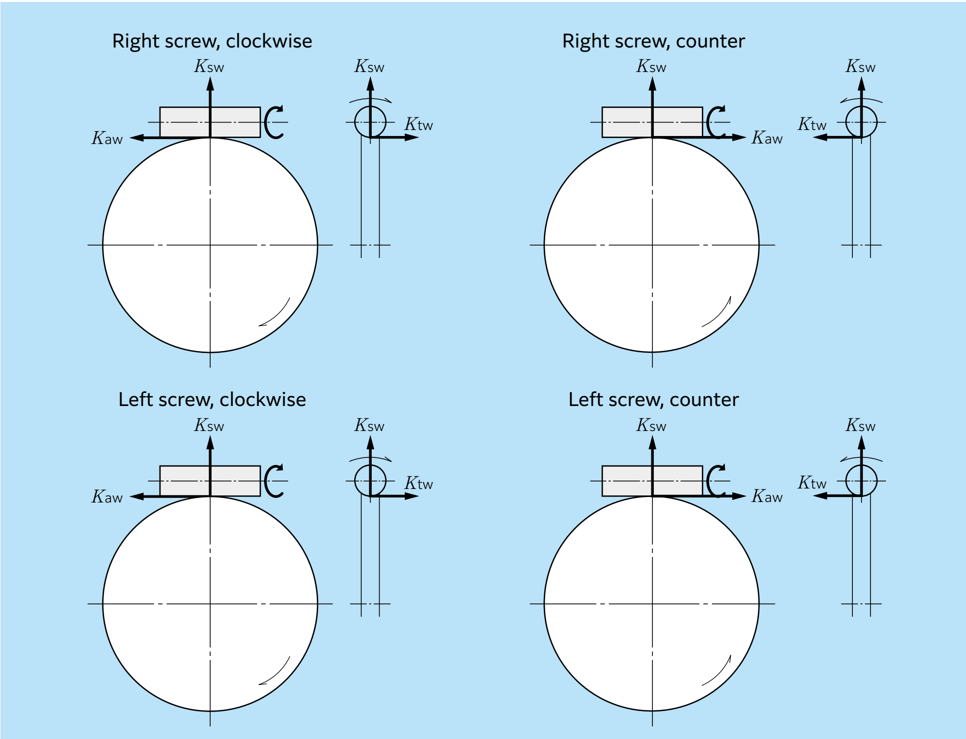

Fig. 4.8 Load acting on worm gears

Table 4.5 Calculation method of load acting on worm gears

Gear type	Worm shaft	Worm gear
Tangential load (tangential force) K_t	$K_{tw}=\dfrac{19.1\times10^{6} H}{n D_{pw}}$	$K_{th}=\dfrac{K_{tw}}{\tan\gamma}=K_{aw}$
Radial load (separating force) K_s	$K_{sw}=\dfrac{K_{tw}\tan\alpha}{\tan\gamma}$	$K_{sh}=\dfrac{K_{tw}\tan\alpha}{\tan\gamma}=K_{sw}$
Parallel load on gear shaft (axial load) K_a	$K_{aw}=\dfrac{K_{tw}}{\tan\gamma}$	$K_{ah}=K_{tw}$

4.1.3 Chain / belt shaft load

The tangential loads on sprockets or pulleys when power (load) is transmitted by means of chains or belts can be calculated by formula (4.19) as shown in **Fig. 4.9**.

$$K_t=\frac{19.1\times10^{6}\cdot H}{D_p\cdot n}\quad\cdots\cdots\cdots\cdots\quad(4.19)$$

Where:

K_t : Sprocket/pulley tangential load, N
H : Transmitted power, kW
D_p : Sprocket/pulley pitch diameter, mm

For belt drives, an initial tension is applied to give sufficient constant operating tension on the belt and pulley.

Taking this tension into account, the radial loads acting on the pulley are expressed by formula (4.20). For chain drives, the same formula can also be used if vibrations and shock loads are taken into consideration.

$$K_r=f_b\cdot K_t\quad\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots(4.20)$$

Where:

K_r : Sprocket or pulley radial load, N
f_b : Chain or belt factor (**Table 4.6**)

Table 4.6 chain or belt factor f_b

Chain or belt type	f_b
Chain (single)	1.2 to 1.5
V-belt	1.5 to 2.0
Timing belt	1.1 to 1.3
Flat belt (w / tension pulley)	2.5 to 3.0
Flat belt	3.0 to 4.0

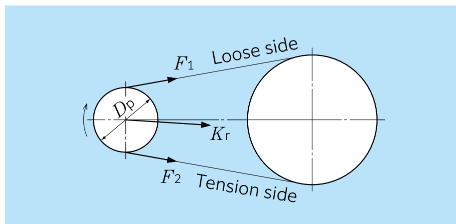

Fig. 4.9 Chain / belt loads

4.2 Bearing load distribution

For shafting, the static tension is considered to be supported by the bearings, and any loads acting on the shafts are distributed to the bearings. For example, in the gear shaft assembly depicted in **Fig. 4.10**, the applied bearing loads can be found by using formulas (4.21) and (4.22).

This example is a simple case, but in reality, many of the calculations are quite complicated.

$$F_{rA}=\frac{a+b}{b}F_{\mathrm{I}}+\frac{d}{c+d}F_{\mathrm{II}}\quad\cdots\cdots\cdots\cdots(4.21)$$

$$F_{rB}=-\frac{a}{b}F_{\mathrm{I}}+\frac{c}{c+d}F_{\mathrm{II}}\quad\cdots\cdots\cdots\cdots(4.22)$$

Where:

F_{rA} : Radial load on bearing A, N
F_{rB} : Radial load on bearing B, N
$F_{\mathrm{I}}, F_{\mathrm{II}}$: Radial load on shaft, N

If directions of radial load differ, the vector sum of each respective load must be determined.

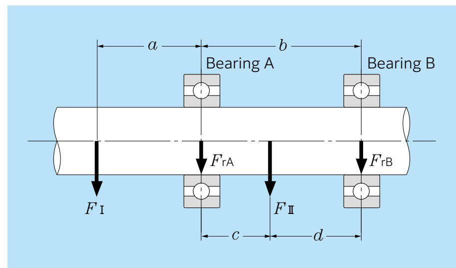

Fig. 4.10

4.3 Mean load

The load on bearings used in machines under normal circumstances will, in many cases, fluctuate according to a fixed time period or planned operation schedule. The load on bearings operating under such conditions can be converted to a mean load (F_m). This is a load which gives bearings the same life they would have under constant operating conditions.

(1) Fluctuating stepped load (Fig. 4.11)

The mean bearing load, F_m, for stepped loads is calculated from formula (4.23). $F_1, F_2 \cdots\cdots F_n$ are the loads acting on the bearing; $n_1, n_2 \cdots\cdots n_n$ and $t_1, t_2 \cdots\cdots t_n$ are the bearing speeds and operating times respectively.

$$F_m = \left[\frac{\Sigma (F_i{}^p n_i t_i)}{\Sigma (n_i t_i)}\right]^{1/p} \cdots\cdots\cdots\cdots\cdots (4.23)$$

Where:

$p = 3$ For ball bearings

$p = 10/3$ For roller bearings

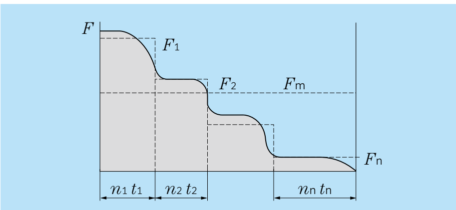

Fig. 4.11 Stepped load

(2) Continuously fluctuating load (Fig. 4.12)

Where it is possible to express the function $F(t)$ in terms of load cycle t_o and time t, the mean load is found by using formula (4.24).

$$F_m = \left[\frac{1}{t_o}\int_o^{t_o} F(t)^p dt\right]^{1/p} \cdots\cdots\cdots\cdots\cdots (4.24)$$

Where:

$p = 3$ For ball bearings

$p = 10/3$ For roller bearings

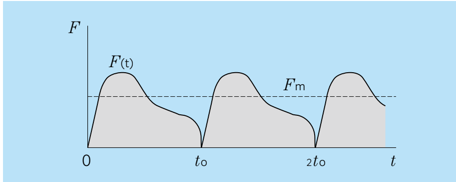

Fig. 4.12 Load that fluctuated as function of time

(3) Linear fluctuating load (Fig. 4.13)

The mean load, F_m, can be approximated by formula (4.25).

$$F_m = \frac{F_{min} + 2F_{max}}{3} \cdots\cdots\cdots\cdots\cdots\cdots (4.25)$$

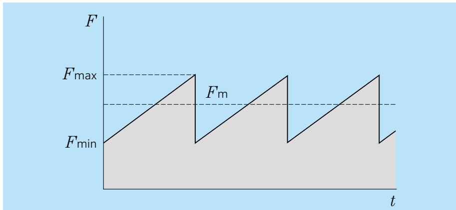

Fig. 4.13 Linear fluctuating load

(4) Sinusoidal fluctuating load (Fig. 4.14)

The mean load, F_m, can be approximated by formulas (4.26) and (4.27).

Case (a) $F_m = 0.75\, F_{max} \cdots\cdots\cdots\cdots\cdots\cdots (4.26)$

Case (b) $F_m = 0.65\, F_{max} \cdots\cdots\cdots\cdots\cdots\cdots (4.27)$

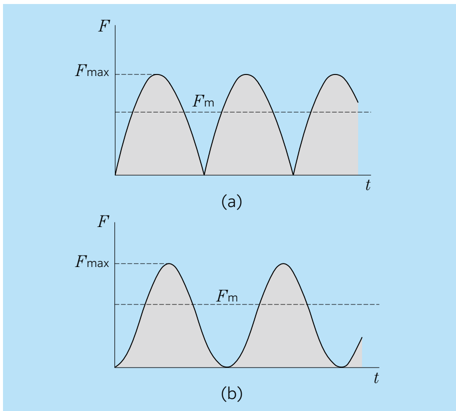

Fig. 4.14 Sinusoidal variable load

4.4 Equivalent load

4.4.1 Dynamic equivalent load

When both dynamic radial loads and dynamic axial loads act on a bearing at the same time, **the hypothetical load acting on the center of the bearing which gives the bearings the same life** as if they had only a radial load or only an axial load **is called the dynamic equivalent load**.

For radial bearings, this load is expressed as pure radial load and is called the dynamic equivalent radial load. For thrust bearings, it is expressed as pure axial load, and is called the dynamic equivalent axial load.

(1) Dynamic equivalent radial load

The dynamic equivalent radial load is expressed by formula (4.28).

$$P_r = XF_r + YF_a \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots (4.28)$$

Where:

P_r : Dynamic equivalent radial load, N

F_r : Actual radial load, N

F_a : Actual axial load, N

X : Radial load factor

Y : Axial load factor

The values for X and Y are listed in the bearing tables.

(2) Dynamic equivalent axial load

As a rule, standard thrust bearings with α contact angle of 90° cannot carry radial loads. However, self-aligning thrust roller bearings can accept some radial load. The dynamic equivalent axial load for these bearings is given in formula (4.29).

$$P_a = F_a + 1.2F_r \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots (4.29)$$

Where:

P_a : Dynamic equivalent axial load, N

F_a : Actual axial load, N

F_r : Actual radial load, N

Provided that $F_r / F_a \leqq 0.55$ only.

4.4.2 Static equivalent load

The static equivalent load is **a hypothetical load which would cause the same total permanent deformation at the most heavily stressed contact point between the rolling elements and the raceway** as under actual load conditions; that is when both static radial loads and static axial loads are simultaneously applied to the bearing.

For radial bearings this hypothetical load refers to pure radial loads, and for thrust bearings it refers to pure centric axial loads. These loads are designated static equivalent radial loads and static equivalent axial loads respectively.

(1) Static equivalent radial load

For radial bearings the static equivalent radial load can be found by using formula (4.30) or (4.31). The greater of the two resultant values is always taken for P_{0r}.

$$P_{0r} = X_0 F_r + Y_0 F_a \cdots\cdots\cdots\cdots\cdots\cdots\cdots (4.30)$$

$$P_{0r} = F_r \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots (4.31)$$

Where:

P_{0r} : Static equivalent radial load, N

F_r : Actual radial load, N

F_a : Actual axial load, N

X_0 : Static radial load factor

Y_0 : Static axial load factor

The values for X_0 and Y_0 are given in the respective bearing tables.

(2) Static equivalent axial load

For spherical thrust roller bearings the static equivalent axial load is expressed by formula (4.32).

$$P_{0a} = F_a + 2.7F_r \cdots\cdots\cdots\cdots\cdots\cdots\cdots (4.32)$$

Where:

P_{0a} : Static equivalent axial load, N

F_a : Actual axial load, N

F_r : Actual radial load, N

Provided that $F_r / F_a \leqq 0.55$ only.

4.4.3 Load calculation for angular contact ball bearings and tapered roller bearings

For angular contact ball bearings and tapered roller bearings the pressure cone apex (load center) is located as shown in **Fig. 4.15**, and their values are listed in the bearing tables.

When radial loads act on these types of bearings a component force is induced in the axial direction. For this reason, these bearings are used in pairs. For load calculation this component force must be taken into consideration and is expressed by formula (4.33).

$$F_a=\frac{0.5F_r}{Y} \quad \cdots\cdots\cdots\cdots\cdots\cdots (4.33)$$

Where:

F_a : Axial component force, N
F_r : Actual radial load, N
Y : Axial load factor

The axial loads for these bearing pairs are given in **Table 4.7.**

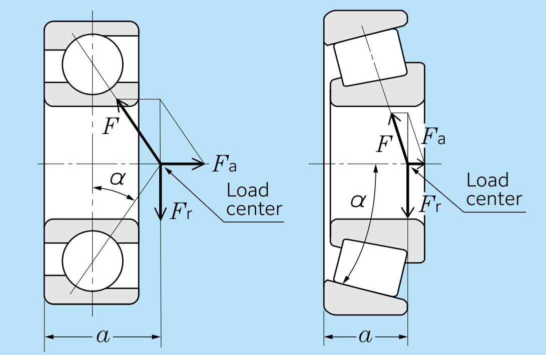

Fig. 4.15 Pressure cone apex and axial component force

Table 4.7 Bearing arrangement and equivalent load

Load center	Load conditions	Axial load
Rear 	$\frac{0.5F_{r\,I}}{Y_{I}} \leqq \frac{0.5F_{r\,II}}{Y_{II}}+F_a$	$F_{a\,I}=\frac{0.5F_{r\,II}}{Y_{II}}+F_a$ ——
Front 	$\frac{0.5F_{r\,I}}{Y_{I}} > \frac{0.5F_{r\,II}}{Y_{II}}+F_a$	—— $F_{a\,II}=\frac{0.5F_{r\,I}}{Y_{I}}-F_a$
Rear 	$\frac{0.5F_{r\,II}}{Y_{II}} \leqq \frac{0.5F_{r\,I}}{Y_{I}}+F_a$	—— $F_{a\,II}=\frac{0.5F_{r\,I}}{Y_{I}}+F_a$
Front 	$\frac{0.5F_{r\,II}}{Y_{II}} > \frac{0.5F_{r\,I}}{Y_{I}}+F_a$	$F_{a\,I}=\frac{0.5F_{r\,II}}{Y_{II}}-F_a$ ——

Note: 1. Applies when preload is zero.
2. Radial forces in the opposite direction to the arrow in the above illustration are also regarded as positive.
3. Dynamic equivalent radial load is calculated by using the table on the right of the size table of the bearing after axial load is obtained for X and Y factor.

4.5 Bearing rating life and load calculation examples

In the examples given in this section, for the purpose of calculation, all hypothetical load factors as well as all calculated load factors may be presumed to be included in the resultant load values.

Bearing loads and the basic rating life of bearings can be calculated using the bearing technical calculation tool on the **NTN** website (https://www.ntnglobal.com).

(Example 1)
What is the rating life in hours of operation L_{10h} for deep groove ball bearing **6208** operating at rotational speed n = 650 min^{-1}, with a radial load F_r of 3.2 kN?

From formula (4.28) the dynamic equivalent radial load P_r:

$P_r=F_r=3.2$kN

Basic dynamic load rating C_r for bearing **6208** given on page B-26 is 32.5 kN, ball bearing speed factor f_n relative to rotational speed n = 650 min^{-1} from **Fig. 3.1** is f_n = 0.37. Thus life factor f_h from formula (3.5) is:

$$f_h=f_n\frac{C_r}{P_r}=0.37\times\frac{32.5}{3.2}=3.76$$

Therefore, with f_h = 3.76 from **Fig. 3.1** the rated life, L_{10h}, is approximately 27 000 hours.

(Example 2)
What is the life rating L_{10h} for the same bearing and conditions as in **Example 1**, but with an additional axial load F_a of 1.8 kN?

To find the dynamic equivalent radial load value for P_r, the radial load factor X, axial load factor Y, and Constant e are used.

Basic static load rating C_{0r} for bearing **6208** given on page B-26 is 17.8 kN and f_0 is 14.0. Therefore:

$$\frac{f_0\cdot F_a}{C_{0r}}=\frac{14\times1.8}{17.8}=1.42$$

Calculated by the proportional interpolation method given on B-27, e = 0.30.

For the operating radial load and axial load:

$$\frac{F_a}{F_r}=\frac{1.8}{3.2}=0.56>e=0.30$$

From B-27, X = 0.56 and Y = 1.44, and from formula (4.28) the dynamic equivalent radial load, P_r, is:

$P_r=XF_r+YF_a$
$=0.56\times3.2+1.43\times1.8$
$=4.38$ kN

From **Fig. 3.1** and **Table 3.1** the life factor, f_h, is:

$$f_h=f_n\frac{C_r}{P_r}=0.37\times\frac{32.5}{4.38}=2.75$$

Therefore, with life factor f_h = 2.75, from **Fig. 3.1** the rated life, L_{10h}, is approximately 10,500 hours.

(Example 3)
Determine the optimum model number for a cylindrical roller bearing operating at the rotational speed n = 450 min^{-1}, with a radial load F_r of 200 kN, and which must have a life (L_{10h}) of over 20 000 hours.

From **Fig. 3.1** the life factor f_h = 3.02 (L_{10h} at 20 000), and the speed factor f_n = 0.46 (n = 450 min^{-1}). To find the required basic dynamic load rating, C_r, formula (3.5) is used.

$$C_r=\frac{f_h}{f_n}P_r=\frac{3.02}{0.46}\times200=1\ 313\text{kN}$$

From page B-108, the smallest bearing that fulfills all the requirements is **NU2332E** (C_r = 1 460 kN).

(Example 4)
The spur gear shown in **Fig. 4.16** (pitch diameter D_p = 150 mm, pressure angle α = 20°) is supported by a pair of tapered roller bearings, **32907XU** (C_r = 30.5 kN) and **32908XU** (C_r = 36.0 kN). Find rating life for each bearing when gear transfer power H = 150 kW and rotational speed n = 2 000 min^{-1}.

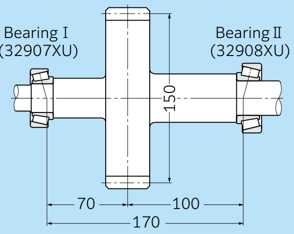

Fig. 4.16 Spur gear diagram

The gear load from formulas (4.3), (4.4a) and (4.5) is:

$$K_t = \frac{19.1\times10^6\cdot H}{D_p\cdot n} = \frac{19\,100\,000\times150}{150\times2\,000}$$
$$= 9.55\text{kN}$$
$$K_s = K_t\cdot\tan\alpha = 9.55\times\tan20°$$
$$= 3.48\text{kN}$$
$$K_r = \sqrt{K_t^2+K_s^2} = \sqrt{9.55^2+3.48^2}$$
$$= 10.16\text{kN}$$

The radial loads for bearings Ⅰ and Ⅱ are:

$$F_{r\,\mathrm{I}} = \frac{100}{170}K_r = \frac{100}{170}\times10.16 = 5.98\text{kN}$$
$$F_{r\,\mathrm{II}} = \frac{70}{170}K_r = \frac{70}{170}\times10.16 = 4.18\text{N}$$
$$\frac{0.5F_{r\,\mathrm{I}}}{Y_{\mathrm{I}}} = 1.45 > \frac{0.5F_{r\,\mathrm{II}}}{Y_{\mathrm{II}}} = 1.01 \text{ Therefore,}$$

The axial loads for bearing Ⅰ and Ⅱ are:

$$F_{a\,\mathrm{I}} = 0\text{kN}$$
$$F_{a\,\mathrm{II}} = \frac{0.5F_{r\,\mathrm{I}}}{Y_{\mathrm{I}}} = \frac{0.5\times5.98}{2.06} = 1.45\text{kN}$$

From page B-137, the dynamic equivalent radial load for bearing Ⅰ is:

$$\frac{F_{a\,\mathrm{I}}}{F_{r\,\mathrm{I}}} = \frac{0}{5.98} = 0 < e = 0.29$$
$$P_{r\,\mathrm{I}} = F_{r\,\mathrm{I}} = 5.98\text{kN}$$

Equally, the dynamic equivalent radial load for bearing Ⅱ is:

$$\frac{F_{a\,\mathrm{II}}}{F_{r\,\mathrm{II}}} = \frac{1.45}{4.18} = 0.35 > e = 0.29$$
$$P_{r\,\mathrm{II}} = XF_{r\,\mathrm{II}} + Y_{\mathrm{II}}F_{a\,\mathrm{II}}$$
$$= 0.4\times4.18 + 2.07\times1.45$$
$$= 4.67\text{kN}$$

From formula (3.5) and **Fig. 3.1** the life factor, f_h, for each bearing is

$$f_{h\,\mathrm{I}} = f_n\frac{C_{r\,\mathrm{I}}}{P_{r\,\mathrm{I}}} = 0.293\times30.5/5.98 = 1.49$$
$$f_{h\,\mathrm{II}} = f_n\frac{C_{r\,\mathrm{II}}}{P_{r\,\mathrm{II}}} = 0.293\times36.0/4.67 = 2.26$$

Therefore, from **Table 3.1**
$L_{h\,\mathrm{I}}$ = 500$f_{h\,\mathrm{I}}$ = 1 900 hours
$L_{h\,\mathrm{II}}$ = 500$f_{h\,\mathrm{II}}$ = 7 550 hours

The combined system bearing life, L_h, from formula (3.3) is:

$$L_h = \frac{1}{\left[\dfrac{1}{L_{h1}^{\,e}} + \dfrac{1}{L_{h2}^{\,e}}\right]^{1/e}}$$
$$= \frac{1}{\left[\dfrac{1}{1\,900^{9/8}} + \dfrac{1}{7\,550^{9/8}}\right]^{8/9}}$$
$$= 1\,600 \text{ hours}$$

(Example 5)
Find the mean load for spherical roller bearing **23932EMD1** (C_r = 455 kN) when operated under the fluctuating conditions shown in **Table 4.8.**

Table 4.8

Condition No. i	Operating time ϕ_i %	Radial load F_{ri} kN	Axial load F_{ai} kN	Rotational speed n_i min^{-1}
1	5	10	2	1 200
2	10	12	4	1 000
3	60	20	6	800
4	15	25	7	600
5	10	30	10	400

The dynamic equivalent radial load, P_r, for each operating condition is found by using formula (4.28) and shown in **Table 4.9** . Because all the values for F_{ri} and F_{ai} from the bearing tables are greater than $F_a / F_r > e$ = 0.17, X = 0.67, Y_2 = 5.81

$$P_{ri} = XF_{ri} + Y_2\,F_{ai} = 0.67F_{ri} + 5.81F_{ai}$$

From formula (4.23) the mean load, F_m, is:

$$F_m = \left[\frac{\Sigma\,(P_{ri}^{\,10/3}\cdot n_i\cdot\phi_i)}{\Sigma\,(n_i\cdot\phi_i)}\right]^{3/10} = 50.0\text{kN}$$

Table 4.9

Condition No. i	Dynamic equivalent radial load. P_{ri} (kN)
1	18.3
2	31.3
3	48.3
4	57.4
5	78.2

(Example 6)
Find the threshold values for rating life time and allowable axial load when cylindrical roller bearing **NUP312** is used under the following conditions:
Provided that intermittent axial load and oil lubricant.
Radial load F_r = 10kN
Rotational speed n = 2 000min^{-1}

Radial load F_r is 10 kN, and
$P_r = F_r$ = 10kN
The speed factor of cylindrical roller bearing, f_n , at n = 2 000 min^{-1} , from **Table 3.1**

$$f_n = \left(\frac{33.3}{2\,000}\right)^{3/10} = 0.293$$

The life factor, f_h , from **Table 3.1**

$$f_h = 0.293\times\frac{137}{10} = 4.01$$

Therefore the basic rated life, L_{10h} , from **Table 3.1**
L_{10h} = 500 × 4.01$^{10/3}$ ≒ 51 000 hours
Next, the allowable axial load of the cylindrical roller bearing is shown on page A-32.
In formula (3.13) on page A-32, based on **NUP312** from **Table 3.7** on page A-33, k = 0.065. In addition, D_{pw} = (60 + 130) / 2 = 95 mm, n = 2 000 min^{-1}.
Thus, the formula below holds when the case of the intermittent axial load is taken into consideration.
$D_{pw}\cdot n$ × 10^4 = 19 × 10^4
In **Fig. 3.16** on page A-33, $D_{pw}\cdot n$ = 19 × 10^4. In the case of the intermittent axial load, allowable surface pressure at the lip P_t = 40 MPa.
Therefore the allowable axial load, P_t , becomes the following.
P_t = 0.065 × 60^2 × 40 = 9 360N
Based on **Table 3.7** on page A-33, it is within the limits of $F_{a\,max}$ < 0.4 × 10 000 = 4 000 N.
Therefore P_t < 4 000 N.

5. Boundary dimensions and bearing number codes

5.1 Boundary dimensions

A rolling bearing's major dimensions, known as "boundary dimensions," are shown in **Figs. 5.1 - 5.3**. To facilitate international bearing interchangeability and economical bearing production, bearing boundary dimensions have been standardized by the International Organization for Standardization (ISO). In Japan, rolling bearing boundary dimensions are regulated by Japanese Industrial Standards (JIS B 1512 series).

Boundary dimensions which have been standardized include: bearing bore diameter, outside diameter, width/height, and chamfer dimensions - all important dimensions when considering the compatibility of shafts, bearings, and housings. However, as a general rule, bearing internal construction dimensions are not covered by these standards.

For metric series rolling bearings there are 90 standardized bore diameters (d) ranging in size from 0.6 mm - 2,500 mm.

Outer diameter dimensions (D) for radial bearings with standardized bore diameter dimensions are covered in the "diameter series;" their corresponding width dimensions (B) are covered in the "width series." For thrust bearings there is no width series; instead, these dimensions are covered in the "height series." The combination of all these series is known as the "dimension series." All series numbers are shown in **Table 5.1**.

Although many rolling bearing dimensions are standardized and have been listed here for purposes of future standardization, there are many standard bearing dimensions which are not presently manufactured.

Boundary dimensions for radial bearings and thrust bearings are shown in the attached tables (I-2 to I-19).

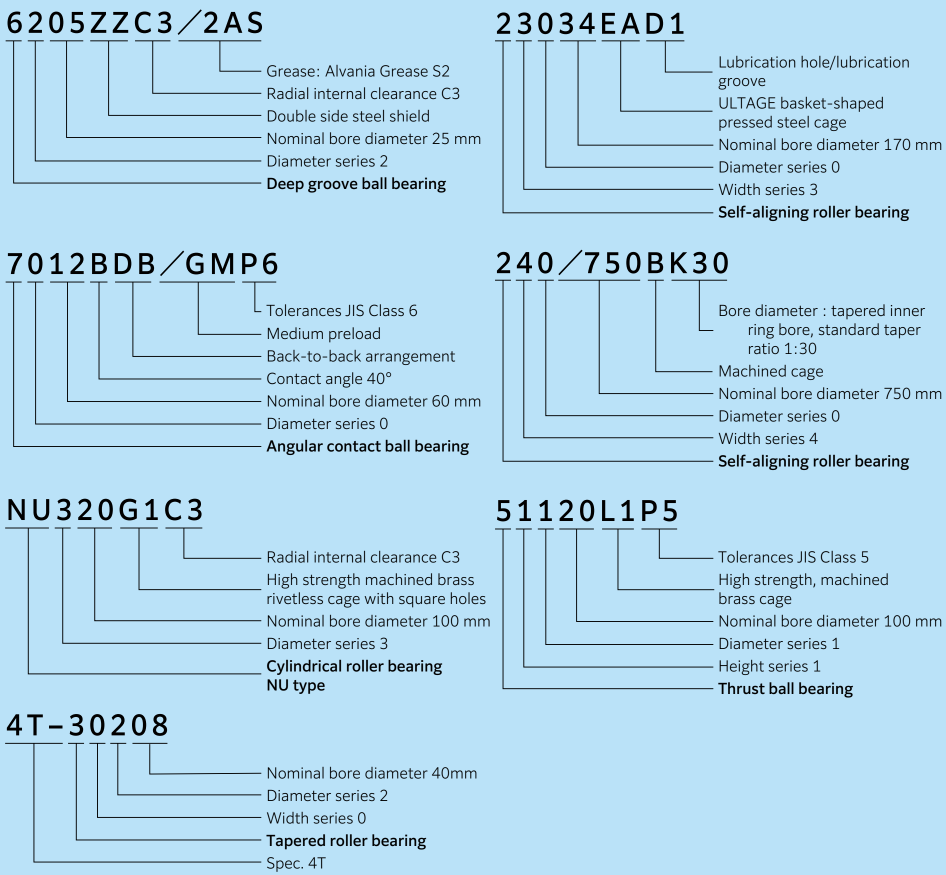
5.2 Bearing numbers

Rolling bearing part numbers indicate **bearing type**, **dimensions**, **tolerances**, **internal construction**, and other related specifications. Bearing numbers are comprised of a "**basic number**" followed by "**supplementary codes**." The makeup and order of bearing numbers is shown in **Table 5.2**.

The **basic number** indicates general information about a bearing, such as its fundamental type, boundary dimensions, series number, bore diameter code and contact angle. The **supplementary codes** derive from prefixes and suffixes which indicate a bearing's tolerances, internal clearances, and related specifications.

(Bearing number examples)



"ULTAGE" (a name created from the combination of "ultimate," signifying refinement, and "stage," signifying **NTN**'s intention that this series of products be employed in diverse applications) is the general name for **NTN**'s new generation of bearings that are noted for their industry-leading performance.

Boundary Dimensions and Bearing Number Codes

Table 5.2 Bearing number composition and arrangement

Supplementary prefix code

Special application/ material/ heat treatment code	
4T-	4T tapered roller bearings
E-	Bearings using case hardened steel
F-	Stainless steel bearings
TS2-	Dimension stabilized bearing for high temperature use (to 160°C)
TS3-	Dimension stabilized bearing for high temperature use (to 200°C)
TS4-	Dimension stabilized bearing for high temperature use (to 250°C)

Basic number — Bearing series

Basic number — Contact angle code

Code [1]	Contact angle
Angular contact ball bearing	
(A)	Standard contact angle 30°
B	Standard contact angle 40°
C	Standard contact angle 15°
Tapered roller bearing	
(B)	Contact angle over 10° to/including 17°
C	Contact angle over 17° to/including 24°
D	Contact angle over 24° to/including 32°

1) Codes in ( ) are not shown in nominal numbers.
Note: Please consult **NTN** Engineering concerning bearing series codes, and supplementary prefix/suffix codes not listed in the above table.

Boundary Dimensions and Bearing Number Codes

Supplementary suffix codes

Internal modifications code

Code	Description
U	Internationally interchangeable tapered roller bearings
R	Non-internationally interchangeable tapered roller bearings
ST	Low torque tapered roller bearings
HT	Angular ball bearings and cylindrical roller bearings for high axial loads
E	High load capacity cylindrical roller bearing
EA	ULTAGE series cylindrical roller bearings
E	ULTAGE series self aligning roller bearings
UTG	ULTAGE series Large tapered roller bearing

Cage code

Code	Description
L1	High strength, machined brass cage
F1	Machined carbon steel cage
G1	High strength machined brass rivetless cage with square holes
G2	Pin type cage
J	Pressed steel cage
T2	Molded resin cage
A	Pressed steel cage (ULTAGE series self aligning roller bearings)
M	High strength, machined brass cage (ULTAGE series self aligning roller bearings)

Seal / Shield code

Code	Description
LB	One-side synthetic rubber seal (non-contact type)
LLB	Double-side synthetic rubber seal (non-contact type)
LU	One-side synthetic rubber seal (contact type)
LLU	Double-side synthetic rubber seal (contact type)
LH	One-side synthetic rubber seal (low-torque type)
LLH	Double-side synthetic rubber seal (low-torque type)
Z	One-side steel Shield
ZZ	Double-side steel Shield

Raceway external configuration code

Code	Description
K	Tapered inner ring bore, standard taper ratio 1:12
K30	Tapered inner ring bore, standard taper ratio 1:30
N	With snap ring groove
NR	Snap ring
D	With oil hole
D1	Lubrication hole/lubrication groove

Duplex arrangement code

Code	Description
DB	Back-to-back arrangement
DF	Face-to-face arrangement
DT	Tandem arrangement
D2	Two matched, paired bearings
+α	Spacer (α = spacer's standard width dimensions)

Internal clearance [1] Preload code

Code	Description
C2	Internal clearance less than normal
(CN)	Normal clearance
C3	Internal clearance greater than normal
C4	Internal clearance greater than C3
C5	Internal clearance greater than C4
CM	Radial internal clearance for electric motor use
/GL	Light preload
/GN	Normal preload
/GM	Medium preload
/GH	Heavy preload

Tolerance code [1]

Code	Description
(P0)	JIS Class 0
P6	JIS Class 6
P5	JIS Class 5
P4	JIS Class 4
P2	JIS Class 2
−4	ABMA Class 4
−2	ABMA Class 2
−3	ABMA Class 3
−0	ABMA Class 0
−00	ABMA Class 00

Lubrication

Code	Description
/2AS	Alvania Grease S2
/3AS	Alvania Grease S3
/8A	Alvania Grease EP2
/5K	Multemp SRL
/LX11	Barrierta JFE552
/LP03	Solid grease

1) Codes in ( ) are not shown in nominal numbers.
Note: Please consult **NTN** Engineering concerning bearing series codes, and supplementary prefix/suffix codes not listed in the above table.

5.2.1 Numbers of inch series tapered roller bearings

The composition of numbers of inch series tapered roller bearings is specified by the American Bearing Manufacturers Association (ABMA). The inner ring component (CONE) and the outer ring (CUP) each have a corresponding number. **Table 5.3** shows the composition of these numbers. Each corresponding code is also described in more detail below.

Table 5.3 Bearing number composition

Prefix code	Contact angle code	Series number	Serial number	Suffix code
XX	○	○○○	○○	XX

Note: X in the table is represented by letters, and ○ is represented by numbers.

XX ○ ○○○ ○○ XX

Load limit code
This code has 9 types from light loads to heavy loads:
EL, LL, L, LM, M, HM, H, HH, and EH.
"J" at the beginning of the code indicates metric bearings.

Contact angle code
This code indicates the contact angle of the series. The classification of each code is shown in **Table 5.3 (1)**.

Series number
A number that is determined by internal specifications.

Serial number
The serial number of the outer ring is 10 to 19.
The serial number of the inner ring is 30 to 49.
Serial numbers exceeding the above are 20 to 29. The outer ring starts from 20, and the inner ring starts from 29 in the opposite direction.

Suffix code
This code consists of either one or two letters. It is used when the appearance and the inside of the standard type are changed.

Table 5.3 (1) Contact angle symbol

Code	Outer ring angle (contact angle × 2) Inc.	Below
1	0°	24°
2	24°	25°30′
3	25°30′	27°
4	27°	28°30′
5	28°30′	30°30′
6	30°30′	32°30′
7	32°30′	36°
8	36°	45°
9	45°(Excluding thrust bearings)	

5.2.2 Numbers of metric tapered roller bearings based on ISO355

Dimension series previously not covered by 3XX are regulated under JIS B 1512. These dimension series are specified in ISO355 and consist of series codes of the angle, diameter, and width. In addition, the inner ring subunit and the outer ring are internationally interchangeable. The composition of bearing numbers are shown in **Table 5.4**. The series codes of the dimension series are shown in **Table 5.4 (1) to (3)**.

Table 5.4 Bearing number composition

Tapered roller bearing code	Dimension series: Angle series	Dimension series: Diameter series	Dimension series: Width series	Bore diameter code
T	○	X	X	○○○

Note: X in the table is represented by letters, and ○ is represented by numbers.

T ○ X X ○○○

Tapered roller bearing code

Angle series code
This code represents the contact angle.
The classification is shown in **Table 5.4 (1)**.

Diameter series code
This code represents the ratio of the bearing outside diameter to the bearing inner diameter. The classification is shown in **Table 5.4 (2)**.

Width series code
This code represents the ratio of the assembly width to the difference between the outer diameter and inner diameter of the single row bearing.
The classification is shown in **Table 5.4 (3)**.

Bore diameter code
The bearing bore diameter is represented in mm.
Example) 040: bore diameter dimension 40 mm

Table 5.4 (1) Angle series code

Code	Contact angle α Over	Incl.
2	10°	13°52′
3	13°52′	15°59′
4	15°59′	18°55′
5	18°55′	23°
6	23°	27°
7	27°	30°

Table 5.4 (2) Diameter series code

Code	$\frac{D}{d^{0.77}}$ Over	Incl.
B	3.4	3.8
C	3.8	4.4
D	4.4	4.7
E	4.7	5
F	5	5.6
G	5.6	7

Note: Quantifiers
d: Nominal inner diameter
D: Nominal outside diameter

Table 5.4 (3) Width series code

Code	$\frac{T}{(D-d)^{0.95}}$ Over	Incl.
B	0.50	0.68
C	0.68	0.80
D	0.80	0.88
E	0.88	1

Note: Quantifiers
d: Nominal inner diameter
D: Nominal outside diameter
T: Assembly width of single row bearing

6. Bearing tolerances

6.1 Dimensional and rotational accuracy

Bearing "tolerances" or dimensional accuracy and running accuracy, are regulated by ISO and JIS standards, JIS B 1514 (rolling bearing tolerances) series. For **dimensional accuracy**, these standards prescribe the tolerances necessary when installing bearings on shafts or in housings. **Running accuracy** is defined as the allowable limits for bearing runout during operation.

Dimensional accuracy

Dimensional accuracy constitutes the acceptable values for bore diameter, outer diameter, assembled bearing width, and bore diameter uniformity as seen in chamfer dimensions, allowable inner ring tapered bore deviation and shape error. Also included are variation of mean bore diameter within a plane, outer diameter within a plane, mean outer diameter within a plane, as well as raceway thickness (for thrust bearings).

Running accuracy

Running accuracy constitutes the acceptable values for inner and outer ring radial runout and axial runout, inner ring side surface squareness, and outer ring outer diameter squareness.

Allowable rolling bearing tolerances have been established according to precision classes. Bearing precision is stipulated as JIS class 6, class 5, class 4, or class 2, with precision rising from ordinary precision indicated by class 0.

Table 6.1 indicates which standards and precision classes are applicable to the major bearing types. **Table 6.2** shows a relative comparison between JIS B 1514 precision class standards and other standards.

For details of allowable limitations and values, refer to **Tables 6.4 - 6.10**, which are described in the application table column of **Table 6.1**. Allowable values for chamfer dimensions are shown in **Table 6.11**. Allowable limitations and values for radial bearing inner ring tapered bores are shown in **Table 6.12**.

Table 6.1 Bearing types and applicable tolerance

Bearing type		Applicable standard	Accuracy class					Tolerance table
Deep groove ball bearings		JIS B 1514-1 (ISO492)	Class 0	Class 6	Class 5	Class 4	Class 2	Table 6.4
Angular contact ball bearings			Class 0	Class 6	Class 5	Class 4	Class 2	
Self-aligning ball bearings			Class 0	—	—	—	—	
Cylindrical roller bearings			Class 0	Class 6	Class 5	Class 4	Class 2	
Needle roller bearings			Class 0	Class 6	Class 5	Class 4	—	
Self-aligning roller bearings			Class 0	—	—	—	—	
Tapered roller bearings	Metric series (single-row)	JIS B 1514	Class 0, 6X	Class 6[1]	Class 5	Class 4	—	Table 6.5
	Metric series (double-row/four-row)	BAS1002	Class 0	—	—	—	—	Table 6.6
	Inch series	ANSI/ABMA Std.19	Class 4	Class 2	Class 3	Class 0	Class 00	Table 6.7
	J series	ANSI/ABMA Std.19.1	Class K	Class N	Class C	Class B	Class A	Table 6.8
Thrust ball bearings		JIS B 1514-2 (ISO199)	Class 0	Class 6	Class 5	Class 4	—	Table 6.9
Spherical roller thrust bearings			Class 0	—	—	—	—	Table 6.10

1) The class is the **NTN** standard class.

Table 6.2 Comparison of tolerance classifications of national standards

Standard	Applicable standard	Accuracy class					Bearing type
Japanese industrial standard (JIS)	JIS B 1514-1	Class 0, 6	Class 6	Class 5	Class 4	Class 2	Radial bearings
	JIS B 1514-2	Class 0	Class 6	Class 5	Class 4	—	Thrust bearings
International Organization for Standardization (ISO)	ISO 492	Normal class Class 6X	Class 6	Class 5	Class 4	Class 2	Radial bearings
	ISO 199	Normal Class	Class 6	Class 5	Class 4	—	Thrust bearings
	ISO 578	Class 4	—	Class 3	Class 0	Class 00	Tapered roller bearings (Inch series)
	ISO 1224	—	—	Class 5A	Class 4A	—	Precision instrument bearings
Deutsches Institut fur Normung (DIN)	DIN 620	P0	P6	P5	P4	P2	All types
American National Standards Institute (ANSI) American Bearing Manufacturer's Association (ABMA)	ANSI/ABMA Std.20 [1]	ABEC-1 RBEC-1	ABEC-3 RBEC-3	ABEC-5 RBEC-5	ABEC-7	ABEC-9	Radial bearings (excluding tapered roller bearings)
	ANSI/ABMA Std.19.1	Class K	Class N	Class C	Class B	Class A	Tapered roller bearings (Metric series)
	ANSI/ABMA Std.19	Class 4	Class 2	Class 3	Class 0	Class 00	Tapered roller bearings (Inch series)

1) "ABEC" is applied to ball bearings and "RBEC" to roller bearings.
Note: 1. JIS B 1514 series, ISO492, 199, and DIN620 have the same specification level.
2. The tolerance and allowance of JIS B 1514 series are slightly different from those of ABMA standards.

Application of accuracy class

Ordinary precision JIS Class 0 is applied to general roller bearings. However, depending on the conditions and applications, bearings with JIS Class 5 or higher may be necessary.

Table 6.3 shows application examples of accuracy class according to the required performance of bearings to be used.

Table 6.3 Application example of accuracy class

Required performance	Application example	Applied accuracy class
Accuracy under high speed	Machine tool main spindles Printing machine body bearings Magnetic tape guides	JIS Class 5, JIS Class 4 or higher JIS Class 5 JIS Class 5
High rotational speed	Jet engine main spindles Turbochargers Machine tool main spindles Touchdown bearings of magnetic bearing spindles for turbo-molecular pumps	JIS Class 4 or higher Equivalent to JIS Class 4 JIS Class 5, JIS Class 4 or higher JIS Class 5
Low torque low noise	Machine tool main spindles Hubs of road bikes Cleaner motors Hand spinners Fan motors	JIS Class 5, JIS Class 4 or higher JIS Class 5 JIS Class 0 JIS Class 0 JIS Class 0

6.2 JIS terms

The following is a description of JIS accuracy terms used in **Table 6.4**.

(However, the outer diameter surface is omitted because the meaning is similar.)

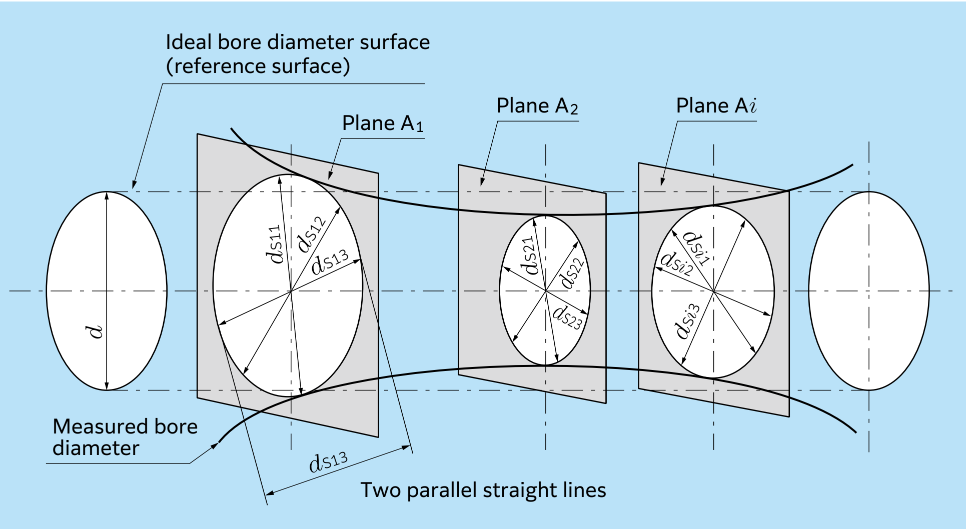

Fig. 6.1 Shape model figure

Terms	Quantifiers	Description
Nominal bore diameter	d	Reference dimension representing the bore diameter size, and reference value with respect to the dimensional difference of the actual bore diameter surface.
Single bore diameter	d_s	Distance between two parallel straight lines that are in contact with the intersection line of the actual bearing bore diameter surface and the radial plane.
Deviation of a single bore diameter	Δ_{ds}	Difference between d_s and d (difference of nominal diameter serving as the measured bore and standard).
Mean bore diameter in a single plane	d_{mp}	Arithmetic mean of the maximum and minimum measured bore diameters within one radial plane. In the model figure, in arbitrary radial plane A_i, when the maximum bore diameter is d_{si1} and the minimum bore diameter is d_{si3}, the value is obtained by $(d_{si1} + d_{si3})/2$. There is one value for each plane.
Mean bore diameter	d_m	Arithmetic mean of the maximum and minimum measured bore diameters obtained from all the cylindrical surfaces. In the model figure, when the maximum measured bore diameter is d_{s11} and the minimum measured bore diameter is d_{s23}, which are obtained from the all the planes A_1, A_2,…A_i, the mean bore diameter is obtained by $(d_{s11} + d_{s23})/2$. There is one value for one cylindrical surface.
Deviation of mean bore diameter	Δ_{dm}	Difference between the mean bore diameter and the nominal bore diameter.
Deviation of mean bore diameter in a single plane	Δ_{dmp}	Difference between the arithmetic mean and the nominal bore diameter of the maximum and minimum measured bore diameters within one radial plane. The value is specified in JIS.
Variation of bore diameter in a single plane	V_{dsp}	Difference between the maximum and minimum measured bore diameters within one radial plane. In the model figure, in radial plane A_1, when the maximum measured bore diameter is d_{s11} and the minimum measured bore diameter is d_{s13}, the difference is V_{dsp} and one value can be obtained for one plane. This characteristic is an index that indicates the roundness. The value is specified in JIS.
Variation of mean bore diameter	V_{dmp}	Difference between the maximum and minimum values of the mean bore diameter within a plane that are obtained from all the planes. A unique value is obtained for each product, and it is near to cylindricity (that is different from geometric cylindricity). The value is specified in JIS.
Nominal inner ring width	B	Distance between both theoretical side surfaces of a raceway. This value is a reference dimension that represents the raceway surface (distance between both side surfaces).
Single inner ring width	B_s	Distance between two intersections. The straight is perpendicular to the plane that is in contact with the inner ring reference side and both actual side surfaces. This value represents the actual width dimension of an inner ring.
Deviation of a single inner ring width	Δ_{Bs}	Difference between the measured inner ring width and the nominal inner ring width. This value is also the difference between the measured inner ring width dimension and the reference dimension that represents the inner ring width. The value is specified in JIS.
Variation of inner ring width	V_{Bs}	Difference between the maximum and minimum measured inner ring widths, which are specified in JIS.
Radial runout of inner ring of assembled bearing	K_{ia}	Difference between the maximum and minimum values of the radial distance between the inner ring bore diameter at each angle position and one fixed point of the outer ring outer diameter surface with respect to radial runout.
Axial runout of inner ring of assembled bearing	S_{ia}	Difference between the maximum and minimum values of the axial distance between the inner ring reference side surface at each angle position and one fixed point of the outer ring outer diameter surface with respect to half the radial distance of the raceway contact diameter from the inner ring central axis and the inner ring of a deep groove ball bearing.

Bearing Tolerances

1) The dimensional difference Δ_{ds} of the measured bore diameter applied to Classes 4 and 2 is the same as the tolerance of dimensional difference Δ_{dmp} of the mean bore diameter within a plane. However, the dimensional difference is applied to diameter series 0, 1, 2, 3 and 4 for Class 4, and also to all the diameter series for Class 2.

2) Applies to ball bearings such as deep groove ball bearings and angular ball bearings.

3) Applies to individual raceway rings manufactured for combined bearing use.

4) The nominal bore diameter of bearings of 0.6 mm is included in this dimensional division.

500	630	—			0	−100

3) Does not apply to bearings with flange.
4) The dimensional difference Δ_{Ds} of the measured outer diameter applied to Class 4 is the same as the tolerance of dimensional difference Δ_{Dmp} of the mean outer diameter within a plane.

5) Applies to bearings with a nominal bore diameter d over 10 mm and 400 mm or less.

Table 6.5 (3) Effective width of inner subunits and outer rings

1) Applies to all radial flat planes of tapered bores.
2) Does not apply to diameter series 7 and 8.
Note: Quantifiers
For a standard taper ratio of $\frac{1}{12}$, $d_1 = d + \frac{1}{12}B$
For a standard taper ratio of $\frac{1}{30}$, $d_1 = d + \frac{1}{30}B$
Δ_{dmp} : Dimensional difference of the mean bore diameter within the flat surface at the theoretical small end of the tapered bore
Δ_{d1mp} : Dimensional difference of the mean bore diameter within the flat surface at the theoretical large end of the tapered bore
V_{dsp} : Unevenness of the bore diameter with the flat surface
B : Nominal width of inner ring
α : $\frac{1}{2}$ of the tapered bore's standard taper angle

For a standard taper ratio of $\frac{1}{12}$
α = 2°23′9.4″
= 2.38594°
= 0.041643 rad

For standard taper ratio of $\frac{1}{30}$
α = 0°57′17.4″
= 0.95484°
= 0.016665 rad

6.4 Bearing tolerance measurement methods

For reference, measurement methods for rolling bearing tolerances are specified in JIS B 1515-2.

Table 6.13 shows some of the major methods of measuring rotation tolerances.

Table 6.13 Rotation tolerance measurement methods

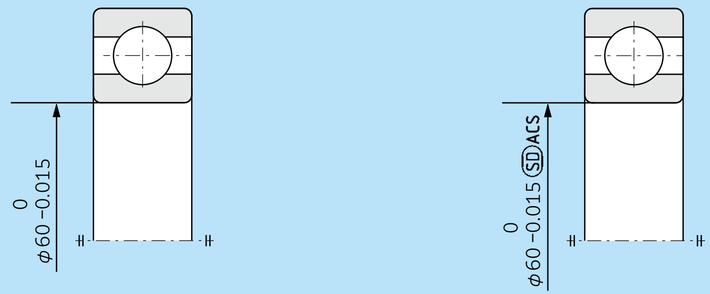
Accuracy characteristics	Measurement methods	
Radial runout of inner ring of assembled bearing (K_{ia})		Radial runout of the inner ring is the difference between the maximum and minimum reading of the measuring device when the inner ring is turned one revolution.
Radial runout of outer ring of assembled bearing (K_{ea})		Radial runout of the outer ring is the difference between the maximum and minimum reading of the measuring device when the outer ring is turned one revolution.
Axial runout of inner ring of assembled bearing (S_{ia})		Axial runout of the inner ring is the difference between the maximum and minimum reading of the measuring device when the inner ring is turned one revolution.
Axial runout of outer ring of assembled bearing (S_{ea})		Axial runout of the outer ring is the difference between the maximum and minimum reading of the measuring device when the outer ring is turned one revolution.
Perpendicularity of inner ring face with respect to the bore (S_d)		The squareness of the inner ring side surface is the difference between the maximum and minimum readings of the measuring device when the inner ring is turned one revolution together with the tapered mandrel.
Perpendicularity of outer ring outside surface with respect to the face (S_D)		The squareness of the outer ring outer diameter surface is the difference between the maximum and minimum readings of the measuring device when the outside ring is turned one revolution along the reinforcing plate.

6.5 Geometrical product specifications (GPS)

GPS is an abbreviation of geometrical product specifications. GPS is the new drawing notation for accurately describing the geometrical specifications of product shapes, dimensions, and surface characteristics. The standard that specifies rules for making drawings with GPS is called "GPS standard."

<Purpose of GPS>

While conventional drawing notation typically describes product dimensions and characteristics accurately, there are several "unclear" aspects of the conventional notation that can lead to varying interpretations (see **Fig. 6.2**). The main purpose of the GPS is to eliminate the ambiguity of drawing notation, thereby preventing troubles.



The dimensional tolerance of bearing bore diameters is specified in ISO/JIS as "Dimensional tolerance of mean bore diameter within plane" (see **Table 6.4 (1)**). However, expressions such as "within plane" and "mean" are omitted in the conventional drawing notation as shown above. This can lead to several interpretations of the dimensional tolerance.

Conventional notation

GPS code "SD" represents "middle" and "ACS" represents "arbitrary cross section." By adding these two codes after the inner bore tolerance, it is possible to clearly express "middle of the measured diameter within an arbitrary cross section", which is the dimensional tolerance of the mean bore diameter within a plane.

GPS notation

Fig. 6.2 Notation example of bearing bore diameter tolerance

<Applying GPS to rolling bearings>
In regards to standards related to roller bearings, ISO 492 specifying the tolerance of radial bearings and ISO 199 specifying the tolerance of thrust bearings were revised with GPS in 2014. In response to this, JIS B 1514–1 and JIS B 1514–2 were also revised in 2017.

<Example of bearing drawing applying GPS>
Fig. 6.3 shows an example of a bearing drawing that uses GPS.

Drawings that use GPS include notations and codes that are different from the ones used in conventional drawings.

For details, please contact **NTN** Engineering.

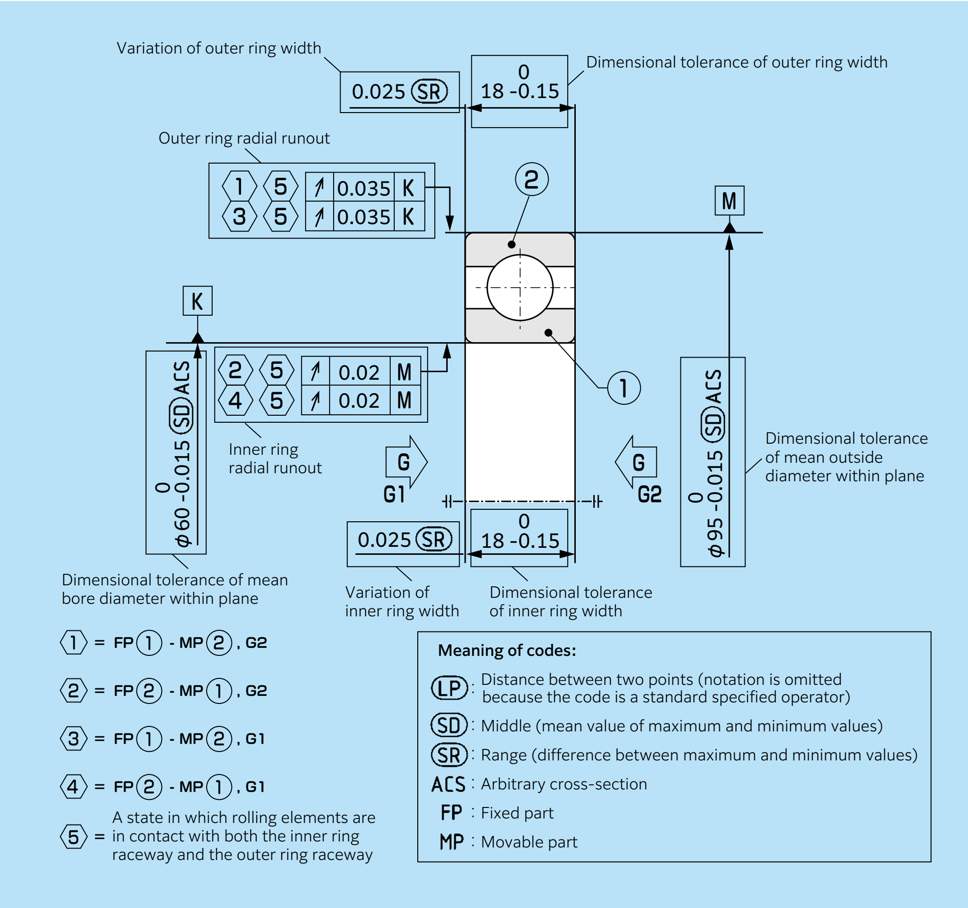


Fig. 6.3 Example of bearing drawing applying GPS

7. Bearing fits

7.1 Resultant fits

For rolling bearings, it is necessary to fix inner and outer rings on the shaft or in the housing so that relative movement does not occur between fitting surfaces during operation or under load. This relative movement between the mating surfaces of the bearing and the shaft or housing can occur in a radial direction, an axial direction, or in the direction of rotation. Types of resultant fit include **tight**, **transition** and **loose fits**, which describe whether or not there is interference between the bearing and the shaft or housing.

The most effective way to fix the mating surfaces between a bearing and shaft or housing is to apply a “tight fit.” The advantage of a tight fit for thin walled bearings is that it provides uniform load support over the entire ring circumference without any loss of load carrying capacity. However, with a tight fit, ease of installation and disassembly is lost; and when using a non-separable bearing as the floating-side bearing, axial displacement is not possible. For this reason, a tight fit cannot be recommended in all cases.

7.2 The necessity of a proper fit

In some cases, an improper fit may lead to damage and shorten bearing life. Therefore it is necessary to carefully select the proper fit. Some possible bearing failures caused by an improper fit are listed below.

- Raceway cracking, early flaking and displacement of raceway
- Raceway and shaft or housing abrasion caused by creeping and fretting corrosion
- Seizing caused by negative internal clearances
- Increased noise and deteriorated rotational accuracy due to raceway groove deformation

Please refer to “16. Bearing Damage and Corrective Measures” for information concerning diagnosis of these conditions.

7.3 Fit selection

Selection of a proper fit is dependent upon thorough analysis of bearing operating conditions, including consideration of:

- Shaft and housing material, wall thickness, surface finish accuracy, etc.
- Machinery operating conditions (nature and magnitude of load, rotational speed, temperature, etc.)

7.3.1 "Tight fit" or "Loose fit"

(1) For bearing rings under rotating loads, a **tight fit** is necessary. (Refer to **Table 7.1**) "Raceways under rotating loads" refers to raceways receiving loads rotating relative to their radial direction.

For bearing rings under static loads, on the other hand, a **loose fit** is sufficient.

(Example) Rotating inner ring load = the direction of the radial load on the inner ring is rotating relatively

(2) For non-separable bearings, such as deep groove ball bearings, it is generally recommended that either the inner ring or outer ring be given a **loose fit**.

Table 7.1 Radial load and bearing fit

Design		Bearing rotation		Ring load	Fit
Static load			Inner ring: Rotating Outer ring: Stationary	Rotating inner ring load Static outer ring load	Inner ring: Tight fit Outer ring: Loose fit
Unbalanced load			Inner ring: Stationary Outer ring: Rotating		
Static load			Inner ring: Stationary Outer ring: Rotating	Static inner ring load Rotating outer ring load	Inner ring: Loose fit Outer ring: Tight fit
Unbalanced load			Inner ring: Rotating Outer ring: Stationary		

7.3.2 Recommended fits

Bearing fit is governed by the tolerances selected for bearing shaft diameters and housing bore diameters.

Widely used fits for Class 0 tolerance bearings and various shaft and housing bore diameter tolerances are shown in **Fig. 7.1**.

Generally-used, standard fits for most types of bearings and operating conditions are shown in **Tables 7.2** to **7.7**.

Table 7.2: Fits for radial bearings
Table 7.3: Fits for thrust bearings
Table 7.4: Fits for electric motor bearings
Table 7.6: Inch series tapered roller bearings Fits of (ANSI/ABMA CLASS 4)
Table 7.7: Inch series tapered roller bearings Fits of (ANSI/ABMA CLASS 3, CLASS 0)

Table 7.5 shows fits and their numerical values.

For special fits or applications, please consult **NTN** Engineering.

7.3.3 Interference minimum and maximum values

The following points should be considered when it is necessary to calculate the interference for an application:

- Regarding minimum values,
  1) interference is reduced by radial loads
  2) interference is reduced by differences between bearing temperature and ambient temperature
  3) interference is reduced by variation in mating surface
  4) interference is reduced by deformation
- The upper limit value should not exceed 1/ 1 000 of the shaft diameter.

Required interference calculations are shown below.

(1) Mating surface variation and interference

Interference decreases because the mating surface is smoothed by the resultant fit (surface roughness is reduced). The amount the interference decreases depends on the roughness of the mating surfaces. It is generally necessary to anticipate the following decrease in interference.

For ground shafts: 1.0 to 2.5 μm
For machined shafts: 5.0 to 7.0 μm

The interference including this decrease amount is called effective interference.

(2) Radial loads and required interference

Interference of the inner ring and shaft decreases when a radial load is applied to the bearing. The interference required for installation to solid shafts is expressed by formulae (7.1) and (7.2) for each load condition.

General applications ($F_r \leqq 0.3C_{0r}$)

$$\Delta d_F = 0.08(d \cdot F_r / B)^{1/2} \text{ N} \quad \cdots\cdots(7.1)$$

Under heavy load conditions ($F_r > 0.3\,C_{0r}$)

$$\Delta d_F = 0.02(F_r / B) \text{ N} \quad \cdots\cdots(7.2)$$

Where:

Δd_F : Required effective interference according to radial load μm
d : Bearing bore mm
B : Inner ring width mm
F_r : Actual radial load, N
C_{0r} : Basic static load rating N

For solid shafts, please contact **NTN** Engineering.

(3) Temperature difference and required interference

Interference between inner rings and steel shafts is reduced as a result of temperature increases (difference between bearing temperature and ambient temperature, ΔT) caused by bearing rotation. Calculation of the minimum required amount of interference in such cases is shown in formula (7.3).

$$\Delta d_T = 0.0015 \cdot d \cdot \Delta T \quad \cdots\cdots(7.3)$$

Δd_T : Required effective interference for temperature difference μm
ΔT : Difference between inner ring temperature and ambient temperature °C
d : Bearing bore mm

(4) Maximum interference

When bearing rings are installed with an interference fit, tensile or compressive stress may occur along their raceways. If interference is too great, this may cause damage to the rings and reduce bearing life. The maximum stress due to the resultant fit must not exceed approximately 127 MPa for safety. If the value is to be exceeded, consult **NTN** Engineering.

See section "17.4 Resultant fit surface pressure" for the calculation method of maximum stress due to the resultant fit.

(5) Interference change amount when materials other than steel are used for shafts and housings

When materials other than steel are used for shafts and housings, the fits between the inner ring and the shaft and the outer ring and the housing change because of difference in the expansion coefficient of each material as the temperature rises during the rotation of the bearing. Therefore, it is necessary to set the resultant fit with expansion coefficients in consideration. The calculation formula of the change in interference is shown below.

$$\Delta d_{TE} = (\alpha_1 - \alpha_2) \times d \times \Delta T$$

Δd_{TE} : Change in interference caused by difference in the expansion coefficients mm

α_1 : Bearing expansion coefficient 1/°C

α_2 : Shaft and housing expansion coefficient 1/°C

d : Reference dimension of resultant fit mm

ΔT : Temperature increase by bearing rotation °C

(Expansion coefficient: See **Table 13.19** in "13. Bearing Materials.")

7.3.4 Other details

(1) Large interference fits are recommended for,
- Operating conditions with large vibrations or shock loads
- Applications using hollow shafts or housings with thin walls
- Applications using housings made of light alloys or plastic

(2) Small interference fits are preferable for,
- Applications requiring high running accuracy
- Applications using small sized bearings or thin walled bearings

(3) Consideration must also be given to the fact that fit selection will effect internal bearing clearance selection. (refer to page A-88.)

(4) A particular type of fit is recommended for SL type cylindrical roller bearings. (refer to page C-67.)

(5) Bearing dimensions are measured and managed at a temperature of 20°C.

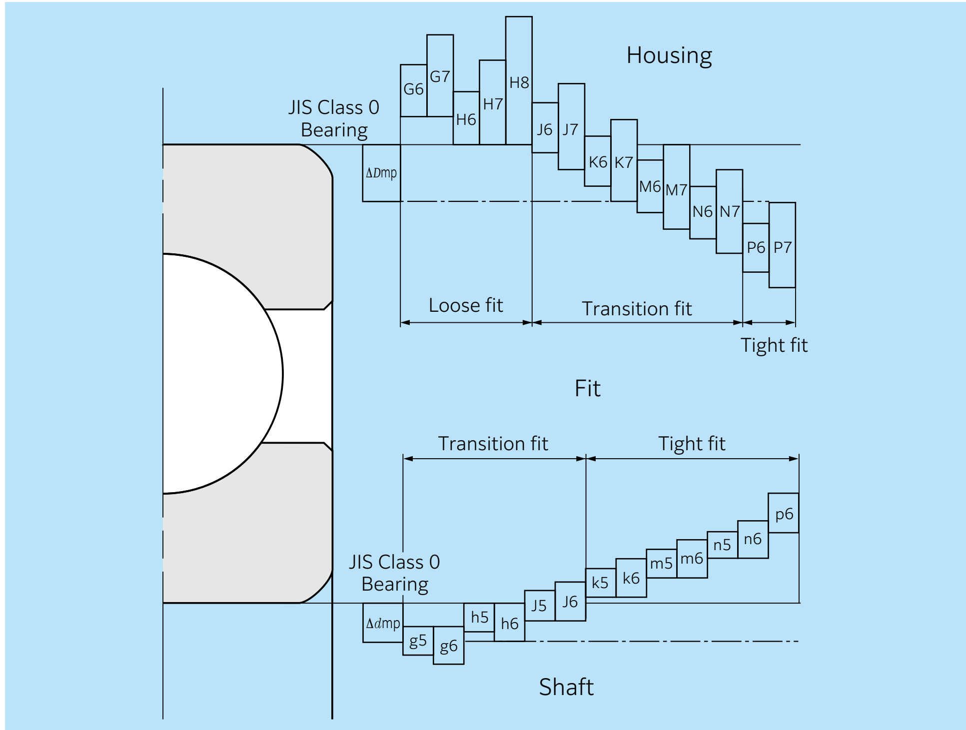

Fig 7.1 State of resultant fit

Bearing Fits

Table 7.2 General standards for radial bearing fits (JIS Class 0, 6X, 6)

		—	—	140	200	100	140	p6	
		—	—	200	—	140	200	r6	
Static inner ring load	Inner ring must move easily over shaft	Overall shaft diameter						g6	When greater accuracy is required use g5. For large bearings, f6 will suffice to facilitate movement.
	Inner ring does not have to move easily over shaft	Overall shaft diameter						h6	When greater accuracy is required use h5.
Center axial load		Overall shaft diameter						js6	Generally, shaft and inner rings are not fixed using resultant fits.
Tapered bore bearing (class 0) (with adapter or withdrawal sleeve)									
Full load		Overall shaft diameter						h9/IT5 [2]	h10/IT7 [2] will suffice for power transmitting shafts.

Table 7.2 (2) Fit with shaft (fits for tapered bore bearings (Class 0) with adapter assembly/ withdrawal sleeve)

Full load	All bearing types	Tolerance class	h9 / IT5 [2]	General applications
			H10 / IT7 [2]	Transmission shafts, etc.

1) Standards for light loads, normal loads, and heavy loads
- Light loads: dynamic equivalent radial load ≦ 0.05 Cr
- Normal loads: 0.05 Cr ≦ dynamic equivalent radial load ≦ 0.10 Cr
- Heavy loads: 0.10 Cr < dynamic equivalent radial load

2) IT5 and IT7 show shaft roundness tolerances, cylindricity tolerances, and related values.

Note: All values and fits listed in the above tables are for solid steel shafts.

Bearing Fits

Table 7.2 (3) Tolerance class of housing bores commonly used for radial bearings (classes 0, 6X and 6)

Conditions: Housing	Conditions: Load type, etc.		Conditions: Outer ring axial direction movement [3]	Housing bore tolerance class	Remarks
Single housing or Divided housing	Static outer ring load	All types of loads	Yes	H7	G7 can be used for large bearings or bearings with large temperature differential between the outer ring and housing.
		Light [1] or ordinary load [1]	Yes	H8	—
		Shaft and inner ring become hot	Easily	G7	F7 be used for large bearings or bearings with large temperature differential between the outer ring and housing.
Single housing		Requires precise rotation under light or ordinary loads	As a rule, it cannot move.	K6	Primarily applies to roller bearings.
			Yes	Js6	Primarily applies to ball bearings.
		Requires low noise operation	Yes	H6	—
	Indeterminate load	Light or ordinary load	Yes	Js7	If high accuracy is required, Js6 and K6 are used in place of Js7 and K7.
		Ordinary or heavy load [1]	As a rule, it cannot move.	K7	
		High impact load	No	M7	—
	Rotating outer ring load	Light or fluctuating load	No	M7	—
		Ordinary or heavy load	No	N7	Primarily applies to ball bearings.
		Heavy load or large impact load with thin wall housing [2]	No	P7	Primarily applies to roller bearings.

1) Standards for light loads, normal loads, and heavy loads
- Light loads: dynamic equivalent radial load ≦ 0.05 Cr
- Normal loads: 0.05 Cr ≦ dynamic equivalent radial load ≦ 0.10 Cr
- Heavy loads: 0.10 Cr < dynamic equivalent radial load

2) The axial direction needs to be secured because the outer ring may move in the shaft direction, causing problems, depending on the use. (Example: planetary gear, etc.)

3) Indicates whether or not outer ring axial movement is possible with non-separable type bearings.

Note: 1. All values and fits listed in the above tables are for cast iron or steel housings.
2. If only a center axial load is applied to the bearing, select a tolerance class that provides clearance for the outer ring in the radial direction.

Table 7.3 Standard fits for thrust bearings (JIS Class 0 and 6)

Table 7.3 (1) Shaft fits

Bearing type	Load conditions		Fit	Shaft diameter mm Over Incl.	Tolerance class
All thrust bearings	Centered axial load only		Transition fit	Overall shaft diameter	js6 or h6
Self-aligning roller thrust bearing	Combined load	Static inner ring load	Transition fit	Overall shaft diameter	js6

1) Fit symbol "**L**" indicates clearance and "**T**" indicates interference.
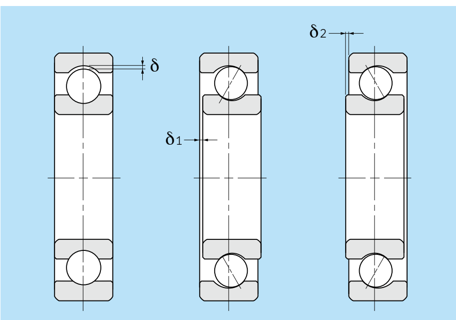
Note: For class 0, bearing outer diameter D applies to 304.8 mm or less.

8. Bearing internal clearance and preload

8.1 Bearing internal clearance

Bearing internal clearance is the amount of internal free movement before mounting. As shown in **Fig. 8.1**, when either the inner ring or the outer ring is fixed and the other ring is free to move, displacement can take place in either an axial or radial direction. This amount of displacement (radially or axially) is termed the internal clearance and, depending on the direction, is called **the radial internal clearance or the axial internal clearance**.

When the internal clearance of a bearing is measured, a slight measurement load is applied to the raceway so the internal clearance may be measured accurately. However, at this time, a slight amount of elastic deformation of the bearing occurs under the measurement load, and the clearance measurement value (measured clearance) is slightly larger than the true clearance. This difference between the true bearing clearance and the increased amount due to the elastic deformation must be compensated for. These compensation values are given in **Table 8.1**. For roller bearings the amount of elastic deformation is small enough to be ignored. The internal clearance values for each bearing class are shown in **Tables 8.8 through 8.16**.



Radial internal clearance = δ
axial internal clearance ≒ $\delta_1 + \delta_2$

Fig. 8.1 Internal clearance

8.2 Selection of internal clearance

The **internal clearance** of a bearing **under operating conditions** (effective clearance) is **usually smaller** than the initial clearance before being installed and operated. This is due to several factors including bearing fit, the difference in temperature between the inner and outer rings, etc. As a bearing's operating clearance has an effect on bearing life, heat generation, vibration, noise, etc.; care must be taken in selecting the most suitable operating clearance.

8.2.1 Criteria for selecting bearing internal clearance

A bearing's life is theoretically at its maximum when operating clearance is slightly negative in steady operation. However, in reality it is difficult to constantly maintain this optimal condition. If the negative clearance becomes larger by fluctuating operating conditions, heat will be produced and the life will decrease severely. Under normal circumstances, a **study should be performed to select an operating clearance slightly larger than zero**. For ordinary operating conditions, use fitting for ordinary loads. If rotational speed and operating temperature are ordinary, selecting normal clearance enables you to obtain the proper operating clearance.

Table 8.2 gives examples applying internal clearances other than CN (normal) clearance.

For the relationship between clearance and life, see the section of "3.8 Clearance and life."

Table 8.1 Adjustment of radial internal clearance based on measured load (deep groove ball bearing)

Commentary

Bearing Internal Clearance and Preload NTN

Table 8.2 Examples of applications where bearing clearances other than CN (normal) clearance are used

Operating conditions	Applications	Selected clearance
With a heavy or shock load, high fit.	Railway vehicle axles	C3
	Vibration screens	C3, C4
With an indeterminate load, both inner and outer rings are tight fit.	Railway vehicle traction motors	C4
	Tractors and final reduction gear	C4
Shaft or inner ring is heated.	Paper making machines and driers	C3, C4
	Table rollers for rolling mill	C3
Required low noise and vibration when rotating.	Small electric motors	C2, CM
Adjustment of clearance to minimize shaft runout.	Main spindles of lathes (Double-row cylindrical roller bearings)	C9NA, C0NA
Loose fit for both inner and outer rings.	Roll neck of steel mill	C2

8.2.2 Calculation of operating clearance

Operating clearance of a bearing can be calculated from initial bearing internal clearance and considering the decrease in clearance due to fitting and the difference in temperature of the inner and outer rings.

$$\Delta_e = \Delta_0 - (\delta_f + \delta_t) = \Delta_f - \delta_t \cdots\cdots\cdots (8.1)$$

Where:
- Δ_e : Effective internal clearance, mm
- Δ_0 : Bearing internal clearance (initial), mm
- Δ_f : Residual clearance (clearance after preloading), mm
- δ_f : Reduced amount of clearance due to fitting, mm
- δ_t : Reduced amount of clearance due to temperature differential of inner and outer rings, mm

(1) Reduced clearance due to fitting

When bearings are installed with interference fits on shafts and in housings, the inner ring will expand and the outer ring will contract; **thus reducing the bearings' internal clearance**.

The amount of expansion or contraction varies depending on the shape of the bearing, the shape of the shaft or housing, dimensions of the respective parts, and the type of materials used. The differential can range from **approximately 70% to 90% of the effective interference**.

$$\delta_f = (0.70 \sim 0.90)\,\Delta d_{eff} \cdots\cdots\cdots\cdots\cdots (8.2)$$

- δ_f : Reduced amount of clearance due to interference, mm
- Δd_{eff} : Effective interference, mm

(2) Residual clearance

When the reduced clearance due to interference is calculated using the expansion rate and the contraction rate of each bearing, the residual clearance is calculated by the formula below.

1) Calculation considering distribution

Assume that the initial clearance, bearing inner ring bore diameter, bearing outer diameter outer diameter, bearing outer diameter, and housing bore diameter follow the normal distribution. The residual clearance is generally calculated as the range of percent defective.

When each dimension and clearance follow the normal distribution and the percent defective is 0.26% (standard range = ±3σ), residual clearance Δ_f can be represented by the formula below.

$$\Delta_f = \Delta_{fm} \pm 3\sigma_{\Delta f} \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots (8.3)$$

Where:
- Δ_{fm} : Average value of standard clearance, mm
- $\sigma_{\Delta f}$: Standard deviation of residual clearance

For the average values and standard deviation of residual clearance, see **Table 8.3** and **Table 8.4**.

2) Calculation by direct sum

When the use condition is severe and calculation is to be done under the worst condition, the maximum and minimum values of each dimension are used for direct sum.

$$\left.\begin{aligned}\Delta_{f\max} &= \Delta_{o\max} - \lambda_i \Delta_{d\min} - \lambda_o \Delta_{D\min}\\ \Delta_{f\min} &= \Delta_{o\min} - \lambda_i \Delta_{d\max} - \lambda_o \Delta_{D\max}\end{aligned}\right\} \quad (8.4)$$

$\Delta_{f\max}$ $\Delta_{f\min}$: Maximum and minimum values of residual clearance, mm

$\Delta_{o\max}$ $\Delta_{o\min}$: Maximum and minimum values of initial clearance, mm

$\Delta_{d\max}$ $\Delta_{d\min}$: Maximum and minimum values of inner ring interference, mm

$\Delta_{D\max}$ $\Delta_{D\min}$: Maximum and minimum values of outer ring interference, mm

λ_i λ_o : Inner ring expansion rate, outer ring contraction rate (See **Table 8.5**)

Table 8.3 Average value and standard deviation of residual clearance

Inner ring fit condition	Outer ring fit condition	Δ_{fm} (Average value of residual clearance)	$\sigma_{\Delta f}$ (Standard deviation of residual clearance)
Tight fit	Loose fit	$\Delta_{0m} - \lambda_I \cdot \Delta_{dm}$	$\sqrt{\sigma_{\Delta 0}^2 + \lambda_I^2 \cdot \sigma_{\Delta d}^2}$
	Tight fit	$\Delta_{0m} - \lambda_I \cdot \Delta_{dm} - \lambda_o \cdot \Delta_{Dm}$	$\sqrt{\sigma_{\Delta 0}^2 + \lambda_I^2 \cdot \sigma_{\Delta d}^2 + \lambda_o^2 \cdot \sigma_{\Delta D}^2}$
Loose fit	Loose fit	Δ_{0m}	$\sigma_{\Delta 0}$
	Tight fit	$\Delta_{0m} - \lambda_o \cdot \Delta_{Dm}$	$\sqrt{\sigma_{\Delta 0}^2 + \lambda_o^2 \cdot \sigma_{\Delta D}^2}$

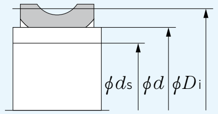
Table 8.4 Symbols and formulas used for calculation

		Average value	Standard deviation	Standard range
Shaft diameter	D_s	D_{sm}	$\sigma_{Ds} = \dfrac{R_{Ds}}{6}$	R_{Ds}
Inner ring bore diameter	d	d_m	$\sigma_d = \dfrac{R_d}{6}$	R_d
Inner ring interference	Δ_d	$\Delta_{dm} = D_{sm} - d_m$	$\sigma_{\Delta d} = \sqrt{\sigma_{Ds}^2 + \sigma_d^2}$	
Housing bore diameter	d_h	d_{hm}	$\sigma_{dh} = \dfrac{R_{dh}}{6}$	R_{dh}
Outer ring outer diameter	D	D_m	$\sigma_D = \dfrac{R_D}{6}$	R_D
Outer ring interference	Δ_D	$\Delta_{Dm} = D_m - d_{hm}$	$\sigma_{\Delta D} = \sqrt{\sigma_D^2 + \sigma_{dh}^2}$	
Initial clearance	Δ_0	Δ_{0m}	$\sigma_{\Delta 0} = \dfrac{R_{\Delta 0}}{6}$	$R_{\Delta 0}$
Residual clearance	Δ_f	Δ_{fm}	$\sigma_{\Delta f}$	
Inner ring expansion rate	λ_I	See **Table 8.5**		
Outer ring contraction rate	λ_o			

Note: When the linear expansion coefficient difference or the temperature difference of the outer ring and the housing or the inner ring and the shaft are to be considered, it is necessary to first calculate using the bearing inner ring bore diameter, bearing outer ring outer diameter, shaft outer diameter, and housing bore diameter before and after the expansion/contraction and then calculate the expansion rate of the raceway and the effective interference.

Table 8.5 Expansion rate and contraction rate of raceway diameter

Fit condition	Calculation item	Calculation formula	Symbol (Unit: N, mm)
Fit of inner ring and shaft (when the inner ring and the shaft are solid steel)	Inner ring expansion rate	$\lambda_I = \dfrac{d}{D_i}$	d : Inner ring bore diameter or shaft diameter d_s : Hollow shaft inner diameter D_i : Inner ring average raceway diameter (refer to **Table 8.7**)
Fit of inner ring and hollow shaft (when the inner ring and the shaft are solid steel)		$\lambda_I = \dfrac{d}{D_i} \cdot \dfrac{\left\{1 - \left(\dfrac{d_s}{d}\right)^2\right\}}{1 - \left\{\left(\dfrac{d}{D_i}\right)^2 \cdot \left(\dfrac{d_s}{d}\right)^2\right\}}$	
Fit of outer ring and housing (when the outer ring and the housing are solid steel)	Outer ring contraction rate	$\lambda_o = \dfrac{D_e}{D} \cdot \dfrac{\left\{1 - \left(\dfrac{D}{D_h}\right)^2\right\}}{1 - \left\{\left(\dfrac{D_e}{D}\right)^2 \cdot \left(\dfrac{D}{D_h}\right)^2\right\}}$	D : Outer ring outer diameter, housing bore diameter D_h : Housing outer diameter D_e : Outer ring average raceway diameter (refer to **Table 8.7**)
	Outer ring contraction rate $D_h = \infty$	$\lambda_o = \dfrac{D_e}{D}$	



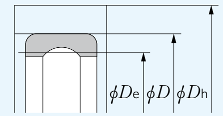


Table 8.6 Fit of two cylinders (general expression)

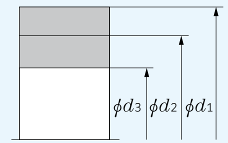
Calculation item	Calculation formula	Symbol (Unit: N, mm)
Expansion rate of outer cylinder outer diameter	$\lambda_1 = \dfrac{E_2\left(\dfrac{(d_1^2+d_2^2)}{(d_1^2-d_2^2)}+1\right)}{E_2\left\{\dfrac{(d_1^2+d_2^2)}{(d_1^2-d_2^2)}+\nu_1\right\}+E_1\left\{\dfrac{(d_2^2+d_3^2)}{(d_2^2-d_3^2)}-\nu_2\right\}} \cdot \dfrac{d_2}{d_1}$	E_1, E_2 : Longitudinal elastic modulus of outer and inner cylinders ν_1, ν_2 : Poisson's ratio of outer and inner cylinders
Contraction rate of inner cylinder bore diameter	$\lambda_2 = \dfrac{E_1\left(\dfrac{(d_2^2+d_3^2)}{(d_2^2-d_3^2)}+1\right)}{E_2\left\{\dfrac{(d_1^2+d_2^2)}{(d_1^2-d_2^2)}+\nu_1\right\}+E_1\left\{\dfrac{(d_2^2+d_3^2)}{(d_2^2-d_3^2)}-\nu_2\right\}} \cdot \dfrac{d_3}{d_2}$	



Note: **Table 13.6** (A-143) in the section of "13. Bearing materials" shows the physical property values of the main materials.

Table 8.7 Average raceway diameter (approximate expression)

Bearing type		Average raceway diameter	
		Inner ring	Outer ring
Ball bearing	All types	$1.05\dfrac{4d+D}{5}$	$0.95\dfrac{d+4D}{5}$
Self-aligning ball bearing	12	$1.03\dfrac{3d+D}{4}$	$0.97\dfrac{d+2D}{3}$
	13, 22	$1.03\dfrac{3d+D}{4}$	$0.97\dfrac{d+3D}{4}$
	23	$1.03\dfrac{4d+D}{5}$	$0.97\dfrac{d+4D}{5}$
Cylindrical roller bearing 1)	All types	$1.05\dfrac{3d+D}{5}$	$0.98\dfrac{d+3D}{4}$
Self-aligning roller bearing	Type B, type C, type 213	$\dfrac{2d+D}{3}$	$0.97\dfrac{d+4D}{5}$
	ULTAGE series	$\dfrac{3d+D}{4}$	$0.98\dfrac{d+5D}{6}$
Tapered roller bearing	All types	$\dfrac{3d+D}{4}$	$\dfrac{d+3D}{4}$

1) Average raceway diameter values shown for double-flange type.

(3) Reduced internal clearance due to inner/ outer ring temperature difference.

During operation, normally the outer ring will range from 5 to 10°C cooler than the inner ring or rotating parts. However, if the cooling effect of the housing is large, the shaft is connected to a heat source, or a heated substance is conducted through the hollow shaft; the temperature difference between the two rings can be even greater. **The amount of internal clearance is thus further reduced** by the differential expansion of the two rings.

$$\delta_t = \alpha \cdot \Delta T \cdot D_o \cdots\cdots\cdots\cdots (8.5)$$

δ_t : Reduced amount of clearance due to temperature differential of inner and outer rings, mm

α : Bearing material expansion coefficient 12.5×10^{-6}/°C

ΔT : Inner/outer ring temperature differential, °C

D_o : Outer ring raceway diameter, mm

Outer ring raceway diameter, D_o, values can be approximated by using formula (8.6) or (8.7).

For ball bearings and spherical roller bearings,

$$D_o = 0.20(d + 4.0D) \cdots\cdots\cdots\cdots (8.6)$$

For roller bearings (except spherical roller bearings),

$$D_o = 0.25(d + 3.0D) \cdots\cdots\cdots\cdots (8.7)$$

d : Bearing bore diameter, mm

D : Bearing outside diameter, mm

For the ULTAGE series bearings, consult **NTN** Engineering.

Note that the formula in item 8.2.2 only applies to steel bearings, shafts and housings.

"Operating clearance calculation (based on 3σ)" can be done by using the bearing technique calculation tool on the **NTN** website (https://www.ntnglobal.com).

8.3 Preload

Normally, bearings are used with a slight internal clearance under operating conditions. However, in some applications, bearings are given an initial load; this means that the bearings' internal clearance is negative before operation. This is called "preload" and is commonly applied to angular ball bearings and tapered roller bearings.

8.3.1 Purpose of preload

The following results are obtained by constant elastic compressive force applied to the contact points of rolling elements and raceway by providing preload.

(1) Bearing's rigidity increases, internal clearance tends not to be produced even when heavy load is applied.
(2) The particular frequency of the bearing increases and is **suitable for high-speed rotation**.
(3) Shaft runout is suppressed; **rotation and position precision are enhanced**.
(4) **Vibration** and **noise** are **controlled**.
(5) Sliding of rolling elements by turning, spinning, or pivoting, is controlled and **smearing is reduced**.
(6) **Fretting** produced by external vibration is prevented.

Applying excessive preload could result in reduction of life, abnormal heating, or increase in turning torque. You should therefore consider the objectives before determining the amount of preload.

Table 8.17 Preloading methods and characteristics

Method	Basic pattern	Applicable bearings	Object	Methods and characteristics	Applications
Fixed position preload		**Angular contact ball bearing**	Maintaining accuracy of rotating shaft, preventing vibration, increasing rigidity	Preloading is accomplished by a predetermined offset of the rings or by using spacers. For the standard preload see **Table 8.18**.	Grinding machines Lathes Milling machines Measuring instruments
		**Tapered roller bearing** **Thrust ball bearing** **Angular contact ball bearing**	Increasing bearing rigidity	Preload is accomplished by adjusting a threaded screw. The amount of preload is set by measuring the starting torque or axial displacement.	Lathes Milling machines Differential gears of automotives Printing machines Wheels
Constant pressure preload		**Angular contact ball bearing** **Deep groove ball bearing** **Tapered roller bearing (high speed)**	Maintaining accuracy and preventing vibration and noise with a constant amount of preload without being affected by loads or temperature	Preloading is accomplished by using coil or belleville springs. For deep groove ball bearings: 4 to 10 d N d: shaft diameter (mm) For angular contact ball bearings: see **Table 8.18**.	Internal grinding machines Electric motors High speed shafts in small machines Tension reels
		**Self-aligning roller thrust bearing** **Cylindrical roller thrust bearing** **Thrust ball bearing**	Preload is primarily used to prevent smearing of opposite axial load side when bearing an axial load.	Preload is accomplished by using coil or belleville springs. Recommended preloads for thrust ball bearings:(larger value of the formulas below is adopted) $T_1 = 0.42\,(nC_{0a})^{1.9} \times 10^{-13}$ N $T_2 = 0.00083\,C_{0a}$ N Self-aligning roller thrust bearing, Cylindrical roller thrust bearing $T = 0.025\,C^{0.8}$ N	Rolling mills Extruding machines

Remarks T : preload, N
n : Rotational speed min^{-1}
C_{0a}: Basic static axial load rating, N

8.3.2 Preloading methods and amounts

The most common method of applying preload on a bearing is to change the relative position of the inner and outer rings of the bearing in the axial direction while applying an axial load between bearings on opposing sides. There are two types of preload: fixed position preload and constant pressure preload.

The basic pattern, purpose and characteristics of bearing preloads are shown in **Table 8.17**.

Fixed position preload

1) Fixed position preload is effective for positioning the two bearings and also for increasing the rigidity.
2) The amount of preload will change due to axial displacement caused by temperature differences between the shaft and housing and the inner and outer rings. Preload will also change as a result of displacement due to loads.

Constant pressure preload

1) Due to the use of a spring for the constant pressure preload, the preloading amount can be kept constant, even when the distance between the two bearings fluctuates under the influence of operating heat and load.
2) Axial loads cannot be applied in the direction in which springs are contracted.

Also, the standard preloading amount for the paired angular contact ball bearings is shown in **Table 8.18**. Light and normal preload is applied to prevent general vibration, and medium and heavy preload is applied especially when rigidity is required.

8.3.3 Preload and rigidity

The increased rigidity effect preloading has on bearings is shown in **Fig. 8.2** to **Fig. 8.4**. When the offset inner rings of the two paired angular contact ball bearings are pressed together, each inner ring is displaced axially by the amount δ_o and is thus given a preload, F_o, in the direction. Under this condition, when external axial load F_a is applied, bearing Ⅰ will have an increased displacement by the amount δ_a and bearing Ⅱ will have a decreased displacement. At this time the loads applied to bearing Ⅰ and Ⅱ are F_{I} and F_{II}, respectively. Under the condition of no preload, bearing Ⅰ will be displaced by the amount δ_b when axial load F_a is applied. Since the amount of displacement, δ_a, is less than δ_b, it indicates a higher rigidity for δ_a.

If a large axial load is to be applied, care must be taken because the preload may be released, causing problems such as heat generation, vibration, and rigidity decrease.

Three-row combinations and two-row combinations are different and have unique right and left displacement diagrams. **Figure 8.3** uses a two-row diagram for bearing Ⅰ, and **Figure 8.4** uses a two-row diagram for bearing Ⅱ. When preload F_o is applied, bearing Ⅰ is displaced by δ_{01} and bearing Ⅱ is displaced by δ_{02}. Under this condition, when axial load F_a is additionally applied, bearing Ⅰ will have an increased displacement by the amount δ_a and bearing Ⅱ will have a decreased displacement.

8.4 Necessary minimum load

In general, when a bearing is operated under no load or a very light load, slippage may occur between the rolling element and the raceway (see "8.3.1 Purpose of preload"). In the case of high-speed rotation, a gyro slip or a cage slip may cause early damage such as smearing. In this case it is necessary to apply a minimum load to prevent slippage during bearing operation.

A rough standard for the necessary minimum radial loads for radial bearings is shown below.

Ball bearings (except self-aligning ball bearings): $0.023\ C_{0r}$
Self-aligning ball bearings: $0.018\ C_{0r}$
Roller bearings: $0.040\ C_{0r}$
Where, C_{0r}: Basic static rating load (N)

∗Consult with **NTN** for the necessary minimum axial loads for thrust bearings.

9. Allowable speed

9.1 Constant speed rotation

As the rotational speed of the bearing increases, the temperature of the bearing also rises due to heat generation inside the bearing due to friction. This may result in damage to the bearing, such as seizure, and the bearing will be unable to continue stable operation. Therefore, the maximum speed at which it is possible for the bearing to continuously operate without the generation of excessive heat beyond specified limits is called the **allowable speed** (min^{-1}). The allowable speed of a bearing depends on the type of bearing, bearing dimensions, type of cage, load, lubrication conditions, and cooling conditions.

The bearing dimensional table gives approximate allowable rotational speeds for grease and oil lubrication.

- The bearing must have the proper internal clearance prescribed in the **NTN** Engineering standard design specifications and must be properly installed.
- A quality lubricant must be used. The lubricant must be replenished and changed when necessary.
- The bearing must be operated at normal operating temperature under ordinary load conditions ($P \leqq 0.08\, C_r$, $F_a / F_r \leqq 0.3$).

If the load is below the minimum necessary load (see section "8. Bearing Internal Clearance and Preload 8.4"), rolling elements may not turn smoothly. If so, please contact **NTN** Engineering for more information. **Allowable rotation for deep groove ball bearings with contact seal (LLU type) or low-torque seal (LLH type) is determined according to the circumferential speed of the seal**. For bearings to be used under heavier than normal load conditions, the allowable speed values listed in the bearing tables must be multiplied by an adjustment factor. The adjustment factors f_L and f_C are given in **Figs. 9.1** and **9.2**.

Also, **when radial bearings are mounted on vertical shafts**, retention of lubricant and cage guidance are less favorable when compared to horizontal shaft mounting. Therefore, the allowable speed should be reduced to **approximately 80% of the listed speed**. For speeds other than those mentioned above, and for which data is incomplete, please consult **NTN** Engineering.

If rotational speed is to exceed allowable rotational speed given in the dimensions table, it will require special considerations, such as using a bearing for which cage specifications, internal clearance and precision have been thoroughly checked. It may require adopting forced circulation, jet oil or mist oil lubrication as the lubrication method.

Under such high speed operating conditions, when special care is taken, the standard allowable speeds given in the bearing tables can be adjusted upward. The maximum speed adjustment values, f_B, by which the bearing table speeds can be multiplied, are shown in **Table 9.1**. However, for any application requiring speeds in excess of the standard allowable speed, please consult **NTN** Engineering.

Polylube bearings (see section 11.4) have their original allowable rotational speed provision. For details, see the special catalogs "**Polylube bearing (CAT. No. 3022/E)**" and "**Polylube needle bearing (CAT. No. 3605/J)**."

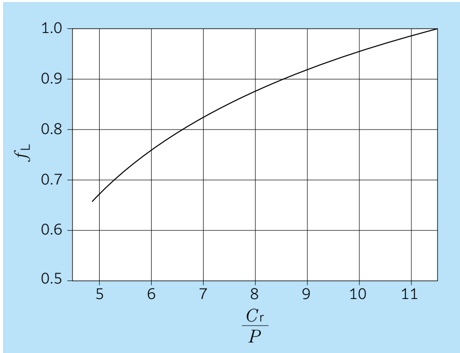

Fig. 9.1 Value of adjustment factor f_L depends on bearing load

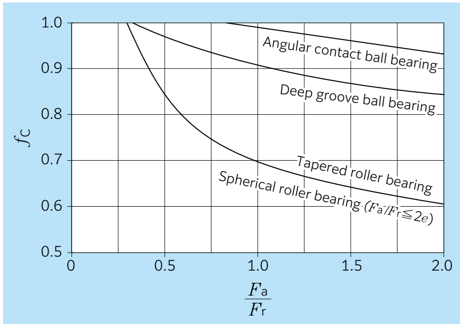

Fig. 9.2 Value of adjustment factor f_C depends on combined load

Table 9.1 Adjustment factor, f_B, for allowable number of revolutions

Bearing type	Adjustment factor f_B
Deep groove ball bearing	3.0
Angular contact ball bearing	2.0
Cylindrical roller bearing	2.5
Tapered roller bearing	2.0

9.2 Low-speed rotation and rapid acceleration/deceleration

When the bearing rotational speed is particularly low (the product of the rotational speed n (min^{-1}) and the rolling element pitch diameter D_{pw} (mm) is $D_{pw}\, n$ < 10 000), an elastohydrodynamic lubrication oil film may not be formed at the contact surface between the rolling element and the raceway surface.

Under such conditions, lubricant containing an extreme-pressure additive (EP additive) should be used.

When rapid acceleration/deceleration is included in the operating conditions, the cage may break.

Please contact **NTN** Engineering because the allowable rotational speed needs to be examined individually.

9.3 Oscillating applications

In small oscillating movement, the rotation direction changes before the bearing makes one rotation.

The moment when the rotation method forwards and reverses, the rotational speed becomes zero. At this time, a lubrication oil film in the fluid mechanics may not be formed or maintained.

Under such conditions, lubricant containing an extreme-pressure additive (EP additive) should be used.

Suitable preload may be applied to reduce the sliding of rolling elements.

When the oscillation angle is extremely small, an oil film is unlikely to be formed on the contact surface between the raceway surface and the rolling element, and fretting (slight abrasion) may occur.

Please contact **NTN** Engineering because the allowable rotational speed needs to be examined individually.

9.4 Heat rating rotational speed

The heat rating rotational speed is an index standardized in JIS B 1550:2010 (ISO 15312:2003) that uses bearing operating temperature as reference.

This standard refers to the rotational speed of the inner ring of the bearing when the heat generation amount due to the bearing internal friction becomes equivalent to the heat radiation amount of the shaft and housing for mounting the bearing in the case where the bearing is operated at the reference condition below.

Reference conditions are shown below.

(1) Reference temperature

Reference temperature of static outer ring (housing raceway washer): 70°C

Reference ambient temperature around bearing: 20°C

(2) Reference load

Radial bearing ($0° \leqq \alpha \leqq 45°$):

Pure radial load of $0.05 \times C_{0r}$

Thrust roller bearing ($45° \leqq \alpha \leqq 90°$):

Pure axial load of $0.02 \times C_{0a}$

(3) Lubricant

The lubricant must be mineral oil that is free of an extreme-pressure additive and have viscosity ν below the following values at 70°C.

Radial bearing:

ν = 12 mm^2/s (equivalent to ISO VG32)

Thrust roller bearing:

ν = 24 mm^2/s (equivalent to ISO VG68)

(4) Lubrication method

In oil bath lubrication, the oil level is the center of the rolling element that is at the lowermost position.

Refer to JIS B 1550:2010 (ISO 15312:2003) for further details.

10. Friction and temperature rise

10.1 Friction

One of the main functions required of a bearing is that it must have low friction. Under normal operating conditions rolling bearings have a much **smaller friction coefficient** than sliding bearings, especially when comparing **starting friction**.

The friction coefficient for rolling bearings is expressed by formula (10.1).

$$\mu = \frac{2M}{Pd} \quad \cdots\cdots\cdots\cdots (10.1)$$

Where:

μ : Friction coefficient

M : Friction moment, N · mm

P : Load, N

d : Bearing bore, mm

The dynamic friction coefficient for rolling bearings varies with the type of bearing, load, lubrication, speed, and other factors. For normal operating conditions, the approximate friction coefficients for various bearing types are listed in **Table 10.1**.

Table 10.1 Friction coefficient for bearings (reference)

Bearing type	Friction coefficient $\mu \times 10^{-3}$
Deep groove ball bearings	1.0～1.5
Angular contact ball bearings	1.2～1.8
Self-aligning ball bearings	0.8～1.2
Cylindrical roller bearings	1.0～1.5
Needle roller bearings	2.0～3.0
Tapered roller bearings	1.7～2.5
Self-aligning roller bearings	2.0～2.5
Thrust ball bearings	1.0～1.5
Thrust roller bearings	2.0～3.0

10.2 Temperature rise

Almost all friction loss in a bearing is transformed into heat within the bearing itself and causes the temperature of the bearing to rise. The amount of thermal generation caused by the friction moment can be calculated using formula (10.2).

$$Q = 0.105 \times 10^{-6} M \times n \quad \cdots\cdots\cdots (10.2)$$

Where:

Q : Thermal value, kW

M : Friction moment, N · mm

n : Rotational speed, min^{-1}

Bearing operating temperature is determined by the equilibrium or balance between the amount of heat generated by the bearing and the amount of heat conducted away from the bearing. In most cases the temperature rises sharply during initial operation, then increases slowly until it reaches a stable condition and then remains constant. The time it takes to reach this steady state depends on the amount of heat produced, heat capacity/diffusion of the shaft and housing, amount of lubricant and method of lubrication. If the temperature continues to rise and does not become constant, it must be assumed that there is some improper function.

When any **abnormal temperature rise** is observed, examine the equipment. Remove the bearing for inspection if necessary. Some possible causes of abnormal temperature rises would be as follows.

- **Bearing misalignment** (due to moment load or incorrect installation)
- **Insufficient internal clearance**
- **Excessive preload**
- **Amount of lubricant too small** or **large**
- **Unsuitable lubricant**
- **Heat generated from sealing mechanism**
- **Excessive load**
- **Rapid acceleration and deceleration**
- **Heat conducted from external sources**

10.3 Starting torque calculation

The starting torque refers to the torque generated at the time of initial bearing rotation, and the torque generation factor differs between ball bearings and roller bearings. For ball bearings, this calculation is shown below with an angular contact ball bearing. For roller bearings, a tapered roller bearing is used as an example.

Even if the actual starting torque value is the same number, the torque calculation value is a reference value because there is measurement variation for each bearing.

1) Preload and staring torque of angular contact ball bearings

Bearings having a contact angle such as angular contact ball bearings and tapered roller bearings cannot be used by themselves. Two bearings must face each other or be used in combination. In this case, the bearings are often used by applying a preload, and the larger the preload is, the larger the friction torque of the bearing becomes. The starting torque of the angular contact ball bearing when a preload is applied generates the majority of the spin slip and the rolling friction torque.

The relationship between the preload and the starting torque of angular contact ball bearings is not a simple proportional relationship, and the calculation is complicated; therefore, please contact **NTN** Engineering.

2) Preload and starting torque of tapered roller bearings

The starting torque of tapered roller bearings are influenced by the following factors.

(1) Sliding friction between roller large end surface and inner ring large rib surface
(2) Rolling friction of rolling surface
(3) Sliding friction of roller and cage
(4) Stirring resistance of lubricant

However, (2) to (4) are extremely small compared with (1); therefore, the starting torque of tapered roller bearings is calculated by (1).

Starting torque M of tapered roller bearings is represented by formula (10.3).

$$M = \mu \cdot \mathrm{e} \cdot \cos(\beta/2) \cdot F_a \quad \mathrm{N \cdot mm} \quad \cdots(10.3)$$

M : Starting torque, N · mm
μ : Friction coefficient
e : Contact position between roller and inner ring rib, mm (**see Figure 10.1**)
β : Roller angle, ° (**see Figure 10.1**)
F_a : Preload, N

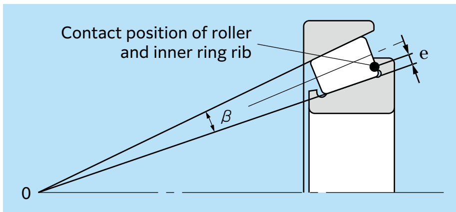

Figure 10.1 β and e

Figure 10.2 shows calculation examples. For details, please contact **NTN** Engineering.

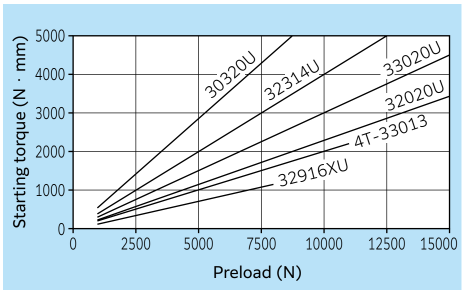

Figure 10.2 Preload and starting torque of tapered roller bearings

11. Lubrication

11.1 Purpose of lubrication

The purpose of rolling bearing lubrication is to prevent direct metallic contact between the various rolling and sliding elements. This is accomplished through the formation of a thin oil (or grease) film on the contact surfaces. Lubricant is necessary for operating rolling bearings. For rolling bearings, lubrication has the following advantages:

(1) **Reduction** of **friction** and **wear**
It prevents direct metallic contact between the rolling and sliding elements of bearing components and reduces friction and wear.
(2) **Prolonged** bearing **life**
The rolling fatigue life is prolonged by forming an oil film on the rolling contact surface part.
(3) **Friction heat dissipation** and cooling
circulating lubrication can dissipate heat generated from friction or conducted from the outside.
(4) Others
It **prevents foreign materials from entering** inside the bearing and suppresses corrosion (rust) by covering the bearing surface with oil.

In order to exhibit these effects, a lubrication method that matches service conditions is required. In addition to this, a quality lubricant must be selected, the proper amount of lubricant must be used and the bearing must be designed to prevent foreign matter from getting in or lubricant from leaking out. If lubrication is insufficient, friction is not reduced, causing excessive rise in bearing temperature or abnormal wear. Therefore, an appropriate lubrication and lubrication method should be selected.

Fig. 11.1 shows the relationship between oil volume, friction loss, and temperature rise. **Table 11.1** details the characteristics of this relationship.

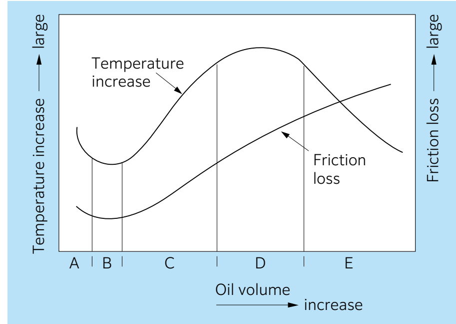

Fig. 11.1

Table 11.1 Oil volume, friction loss, and temperature increase (See Fig. 11.1)

Range	Characteristics	Lubrication method
A	When oil volume is extremely low, direct metallic contact occurs in places between the rolling elements and raceway surfaces. Bearing abrasion and seizing may occur.	—
B	A thin oil film develops over all surfaces, friction is minimal and bearing temperature is low.	Grease lubrication Oil mist Air-oil lubrication
C	As oil volume increases, heat buildup is balanced by cooling.	Circulating lubrication
D	Regardless of oil volume, temperature increases at a fixed rate.	Circulating lubrication
E	As oil volume increases, cooling dominates and bearing temperature decreases.	Forced circulation lubrication Oil jet lubrication

11.2 Lubrication methods and characteristics

Lubrication methods for bearings can be roughly divided into **grease** and **oil lubrication**. Each of these has its own features, so the lubrication method that best offers the required function must be selected.

Characteristics of each method are shown in **Table 11.2**.

Table 11.2 Comparison of grease lubrication and oil lubrication characteristics

Concern \ Method	Grease lubrication	Oil lubrication
Handling	◎	△
Reliability	○	◎
Cooling effect	×	○ (Circulation necessary)
Seal structure	○	△
Power loss	○	○
Environment contamination	○	△
High speed rotation	×	○

◎ : Very good ○ : Good △ : Fair × : Poor

11.3 Grease lubrication

Grease lubricants are relatively easy to handle and require only the simplest sealing devices. For these reasons, grease is the most widely used lubricant for rolling bearings. It is used in a bearing that is pre-sealed with grease (sealed/shielded bearing), or if using an unsealed bearing, fill the bearing and housing with the proper amount of grease, and replenish or change the grease regularly.

With sealed bearings, the proper grease amount does not cause leakage; however, under use conditions including a lot of vibrations, which cause grease to flow easily, or under high-speed outer ring rotation, in which large centrifugal force is applied on the grease, the grease may purge (in rare cases). Please consult **NTN** Engineering.

11.3.1 Types and characteristics of grease

Lubricating grease is composed of either a mineral base oil or a synthetic base oil. **To this base a thickener and other additives are added**. The properties of all greases are mainly determined by the kind of base oil used and by the combination of thickening agent and various additives. **Table 11.5** shows general grease varieties and characteristics, and **Table 11.6** shows grease brand names and their characteristics. (See pages A-116 and A-117.) As performance characteristics of even the same type of grease will vary widely from brand to brand, **it is necessary to check the manufacturers' data when selecting grease**.

(1) Base oil

Mineral oil or synthetics such as **ester oil**, **synthetic hydrocarbon oil**, or **ether oil** are used as the base of greases.

Generally, greases with low viscosity base oils are best suited for low temperatures and high speeds; grease using high-viscosity base oil has superior high-temperature and high-load characteristics.

(2) Thickening agents

Thickening agents are compounded with base oils to maintain the semi-solid state of the grease. Thickening agents consist of two types of bases: metallic soaps and non-soaps. Metallic soap thickeners include: **lithium**, **sodium**, **calcium**, etc. Non-soap base thickeners are divided into two groups: inorganic (**silica gel**, **bentonite**, etc.) and organic (**polyurea**, **fluorocarbon**, etc.). The various special characteristics of a grease, such as **limiting temperature range**, **mechanical stability**, water resistance, etc. depend largely on the type of **thickening agent** used. For example, a sodium based grease is generally poor in water resistance properties, while greases with bentone, poly-urea and other non-metallic soaps as the thickening agent are generally superior in high temperature properties.

(3) Additives

Various additives are added to grease depending on the purpose. Typical additives include **anti-oxidants**, **high-pressure additives** (EP additives), **rust preventives**, and **anti-corrosives**. For bearings subject to heavy loads and/or shock loads, grease containing high-pressure additives should be used. Anti-oxidants are added to grease used in most types of rolling bearings.

(4) Consistency

Consistency is an index that indicates hardness and fluidity of grease. **The higher the NLGI number, the HARDER the grease is**. For the lubrication of rolling bearings, greases with the NLGI consistency numbers of 1, 2, and 3 are used. General relationships between consistency and application of grease are shown in **Table 11.3**.

Table 11.3 Consistency of grease

NLGI consistency No.	JIS(ASTM) 60 times blend consistency	Application
0	355 to 385	For centralized greasing use
1	310 to 340	For centralized greasing use
2	265 to 295	For general use and sealed bearing use
3	220 to 250	For general use, high temperature use, and sealed bearing use
4	175 to 205	For special use

(5) Mixing different types of greases

When greases of different kinds are mixed together, the consistency of the greases will change (usually softer), the operating temperature range will be lowered, and other changes in characteristics will occur. As a rule, grease should not be mixed with grease of any other brand. However, if different greases must be mixed, at least greases with the same base oil and thickening agent should be selected.

11.3.2 Amount of grease

The amount of grease used in any given situation will depend on many factors relating to the size and shape of the housing, space limitations, bearing's rotating speed and type of grease used. As a rule of thumb, **bearings should be filled to 30 to 40% of their space and housing should be filled 30 to 60%**. Where speeds are high and temperature rises need to be kept to a minimum, a reduced amount of grease should be used. **Excessive amounts of grease cause temperature rises which in turn cause the grease to soften and may allow leakage. Oxidation and deterioration of excessive grease fills may cause the lubricating efficiency to be lowered.** Moreover, the standard bearing space can be found by formula (11.1)

$$V = K \cdot W \quad \cdots\cdots (11.1)$$

where,

V : Quantity of bearing space open type (approx.), cm^3

K : Bearing space factor (see value of K in **Table 11.4**)

W : Mass of bearing, kg

A predetermine amount of grease is filled in the bearing with a grease gun or a syringe. After sealing it is not possible to spread the grease by hand - only by rotating the bearing by hand.

Table 11.4 Bearing space factor K

Bearing type[1)]			Cage type	K

Characteristics/ application	Balanced performance with less disadvantages All purpose grease	Excellent low temperature and wear characteristics Suitable for small sized and miniature bearings	Excellent characteristics at low and high temperatures Poor load resistance	Balanced performance with less disadvantages Usable for relatively high temperature	Used for low speed and light loads Unusable for high temperature	Excellent pressure resistance	Some emulsification when water is introduced Usable for relatively high temperature	Excellent water resistance and oxidation stability	Excellent water resistance and oxidation stability Used for high temperature and high speed applications	Excellent chemical resistance Used for high temperature applications	Excellent characteristics at low temperature

1) Use the grease performance as rough standards because it differs depending on the manufacturer's additive formation.
2) Na soap-based grease may be emulsified by water and high humidity conditions.
Urea-based grease may deteriorate polyfluorocarbons and rubber.
3) Ester oil-based grease may swell acrylic materials, and silicone-based grease may swell silicone materials.
Some silicone-based greases and fluorine-based greases have poor noise performance and rustproofing performance.

Table 11.6 Grease brands and their nature

Brand	Code	Thickener	Base oil	Base oil viscosity mm²/s		60 times blend consistency		Dropping point °C	Operating temperature range °C	Characteristics
				40°C	100°C	Representative value	NLGI No			
Alvania Grease S2	2AS	Li soap	Mineral oil	131	12.2	283	2	181	−25 to 120	All-purpose (standard grease for deep grease ball bearings)
Alvania Grease S3	3AS	Li soap	Mineral oil	131	12.2	242	3	182	−20 to 135	All-purpose (standard grease for ball bearings of bearing units)
Alvania EP Grease 2	8A	Li soap	Mineral oil	220	15.9	284	2	184	−20 to 110	All-purpose for high loads
Multemp PS No. 2	1K	Li soap	Ester + PAO	15.9	—	270	2	190	−50 to 130	For low temperature and low torque
Multemp SRL	5K	Li soap	Ester	24.1	—	250	2 to 3	192	−40 to 150	For low temperature to high temperature, all-purpose (standard grease for miniature/small diameter ball bearings)
SH33L	3L	Li soap	Silicone	70	27	320	1 to 2	220	−70 to 140	For low temperature
SH44M	4M	Li soap	Silicone	80	19	260	2 to 3	204	−40 to 160	For high temperature
ISOFLEX NBU15	15K	Ba complexed soap	Diester + mineral oil	23	5	280	2	220 or above	−40 to 130	For high speed
SHC POLYREX 462	L791	Urea	PAO	460	40	280	2	270	−20 to 170	For food machinery
SE-1	L749	Urea	PAO + ester	22	5	265	2	220 or above	−50 to 120	For high speed
ME-1	L700	Urea	Ester + PAO	61.3	9.3	231	3	250 or above	−30 to 160	For high temperature and high speed
EP-1	L542	Urea	PAO	46.8	—	220	2	260 or above	−40 to 160	For high temperature and high speed
NA103A	L756	Urea	PAO + ether	53.5	—	270	2	260 or above	−40 to 180	Brittle separation
MP-1	L448	Urea	Synthetic oil	40.6	7.1	243	3	250 or above	−40 to 150	For high temperature and high speed
Grease J	L353	Urea	Ester	75	10	305	1 to 2	280 or above	−20 to 180	For high temperature
Cosmo Wide Grease WR3	2M	Na terephthalate	Diester + mineral oil	31.6	6	238	3	230 or above	−40 to 150	For low temperature to high temperature, all-purpose
Mobilgrease 28	9B	Bentonite	PAO	30	5.7	293	1 to 2	307	−54 to 177	MIL-PRF-81322 For low temperature to high temperature
Aeroshell Grease 7	5S	Microgel	Diester	10.3	3.1	296	1 to 2	260 or above	−73 to 149	MIL-PRF-23827C

Note: 1. Representative values are shown for the base oil viscosity, consistency, and dropping point.
2. The upper and lower limits of the operating temperature range differ depending on the usage environment and requirement specifications. Please consult with **NTN** Engineering.

11.3.3 Grease replenishment

As the lubricating performance of grease declines with the time, grease must be filled in proper intervals.

The replenishment interval depends on the type of bearing, dimensions, bearing's rotating speed, bearing temperature, and type of grease. An easy reference chart for calculating grease replenishment interval is shown in **Fig. 11.2**. This chart indicates the replenishment interval for standard rolling bearing grease when used under normal operating conditions. As operating temperatures increase, the grease interval should be shortened accordingly. Generally, for every 10°C increase in bearing temperature above 80°C, the grease interval period is shortened to "2/3".

For grease replenishment interval of the ULTAGE series, please contact **NTN** Engineering.

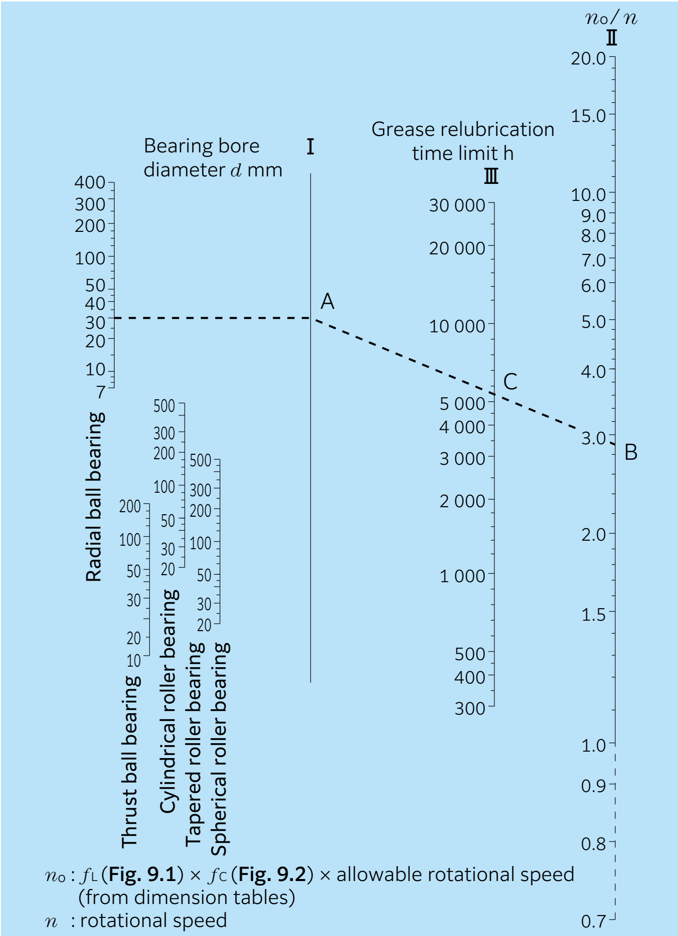

Fig. 11.2 Diagram for grease interval

(Example) Find the grease relubrication time limit for deep groove ball bearing 6206, with a radial load of 2.0 kN operating at 3 600 min^{-1}

From **Fig. 9.1** C_r / P_r = 21.6 / 2.0 kN = 10.8, f_L = 0.96. Allowable rotational speed from the dimensions tables for bearing 6206 is 11 000 min^{-1}. Allowable rotational speed n_o for 2.0 kN radial load is:

$$n_o = 0.96 \times 11\,000 = 10\,560 \text{min}^{-1}$$

Therefore, $\frac{n_o}{n} = \frac{10\,560}{3\,600} = 2.93$

The point where vertical line Ⅰ intersects a horizontal line drawn from the point equivalent of d = 30 for the radial ball bearing shown in **Fig. 11.2** shall be point A. Find intersection point C where vertical line Ⅲ intersects the straight line formed by joining point B (n_o / n = 2.93) with A by a straight line Ⅱ. It shows that grease life in this case is approximately 5,500 hours.

11.3.4 Grease life estimation of sealed ball bearings

There is a method of estimating the grease life of single row sealed and greased ball bearings.

The estimated grease life changes depending on the grease type, temperature, shaft rotational speed, and load; therefore, please contact **NTN** Engineering for details.

11.4 Solid grease

"Solid grease" is a lubricant composed mainly of lubricating grease and ultra-high polymer polyethylene. Solid grease begins as grease that has the same viscosity as a more traditional grease. After being heated and cooled, a process known a "calcination", the grease hardens while maintaining a large quantity of lubricant within the polymer structure. The result of this solidification is that the grease does not easily leak from the bearing, even when the bearing is subjected to strong vibrations or centrifugal force.

Bearings with solid grease are available in two types: the spot-pack type in which solid grease is injected into the cage, and the full-pack type in which all free space around the rolling elements is completely filled with solid grease.

Spot-pack solid grease is available for deep groove ball bearings, small diameter ball bearings, and bearing units. Full-pack solid grease is available for self-aligning ball bearings, spherical roller bearings, and needle roller bearings.

Primary advantages:

(1) Minimal grease leakage

(2) Low bearing torque with spot-pack type solid grease

For more details, please refer to the special catalog "**Bearings with solid grease (CAT. No. 3022/E).**"

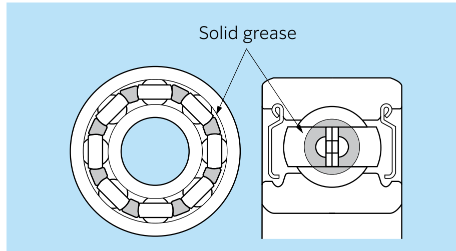

Fig. 11.3 Deep groove ball bearing with spot-pack solid grease (Z shield) (Available for deep groove ball bearings)

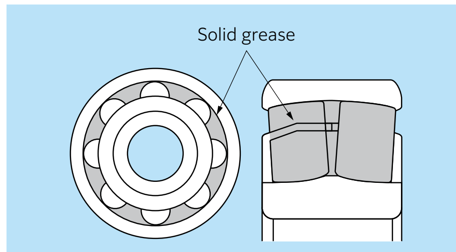

Fig. 11.4 Spherical roller bearing with full-pack solid grease (Available for spherical roller bearings)

11.5. Oil lubrication

Oil lubrication is suitable for applications requiring that bearing-generated heat or heat applied to the bearing from other sources be carried away from the bearing and dissipated to the outside.

Table 11.7 shows the main methods of oil lubrication.

Table 11.7 Oil lubrication methods

Lubrication method	Example	Lubrication method	Example
(Oil bath lubrication) ● Oil bath lubrication is the most generally used method of lubrication, and is widely used for low to moderate rotational speed applications. ● For horizontal shaft applications, oil level should be maintained at approximately the center of the lowest rolling element, according to the oil gauge, when the bearing is at rest. For vertical shafts at low speeds, oil level should be maintained at 50 - 80% submergence of the rolling elements.		**(Disc lubrication)** ● In this method, a partially submerged disc rotates and pulls oil up into a reservoir from which it then drains down through the bearing, lubricating it.	(Oil spray lubrication) ● In this method, an impeller or similar device mounted on the shaft draws up oil and sprays it onto the bearing. This method can be used at considerably high speeds.		**(Oil mist lubrication)** ● Using pressurized air, lubricating oil is atomized before passing through the bearing. ● Due to the low lubricant resistance, this method is well suited to high speed applications.	(Drip lubrication) ● In this method, oil is collected above the bearing and allowed to drip down into the housing where it becomes a lubricating mist as it strikes the rolling elements. Another version allows only slight amounts of oil to pass through the bearing. ● Used at relatively high speeds for light to moderate load applications. ● In most cases, oil volume is a few drops per minute.		**(Air-oil lubrication)** ● In this method, the required minimum amount of lubricating oil is measured and fed to each bearing at ideal intervals using compressed air. ● Fresh lubricating oil is constantly fed. ● Because the required oil quantity is very small, the working environment can be kept clean.	(Circulating lubrication) ● Used for bearing cooling or for automatic oil supply systems in which the oil supply is centrally located. ● One of the advantages of this method is that oil cooling devices and filters to maintain oil purity can be installed within the system. ● In order for oil to thoroughly lubricate the bearing, oil inlets and outlets must be provided on opposite sides of the bearing.		**(Oil jet lubrication)** ● This method lubricates by injecting oil under high pressure directly into the side of the bearing. This is a reliable system for high speed, high temperature or otherwise severe conditions. ● Used for lubricating the bearings in jet engines, gas turbines, and other high speed equipment. ● Under-race lubrication is one example of this type of lubrication.	
11.5.1 Selection of lubricating oil

Under normal operating conditions, **machine oil**, **turbine oil**, and other mineral oils are widely used for the lubrication of rolling bearings. However, for temperatures **below -30°C** or **above 150°C**, synthetic oils such as **ester oil**, **silicone oil**, and **fluorinated oil** are used.

For lubricating oils, viscosity is one of the most important properties and determines an oil's lubricating efficiency. If viscosity is too low, formation of the oil film will be insufficient, and damage to the rolling surface will occur. If viscosity is too high, viscous resistance will also be great, resulting in temperature increase and friction loss. In general, **for higher speed applications, a lower viscosity oil** should be used; **for heavier load applications, a higher viscosity oil** should be used.

Lubrication of rolling bearings requires viscosity shown in **Table 11.8**, which is dependent on the use conditions. **Fig 11.5** shows the relation between lubricating oil viscosity and temperature. This is used to select a lubrication oil with viscosity characteristics appropriate for the operating temperature.

For reference, **Table 11.9** lists the selection standards for lubricating oil viscosity based on bearing operating conditions.

Table 11.8 Required lubricating oil viscosity for bearings

Bearing type	Dynamic viscosity mm^2/s
Ball bearings, Cylindrical roller bearings, Needle roller bearings	13 or above
Spherical roller bearings, Tapered roller bearings, Needle roller thrust bearings	20 or above
Self-aligning roller thrust bearing	30 or above

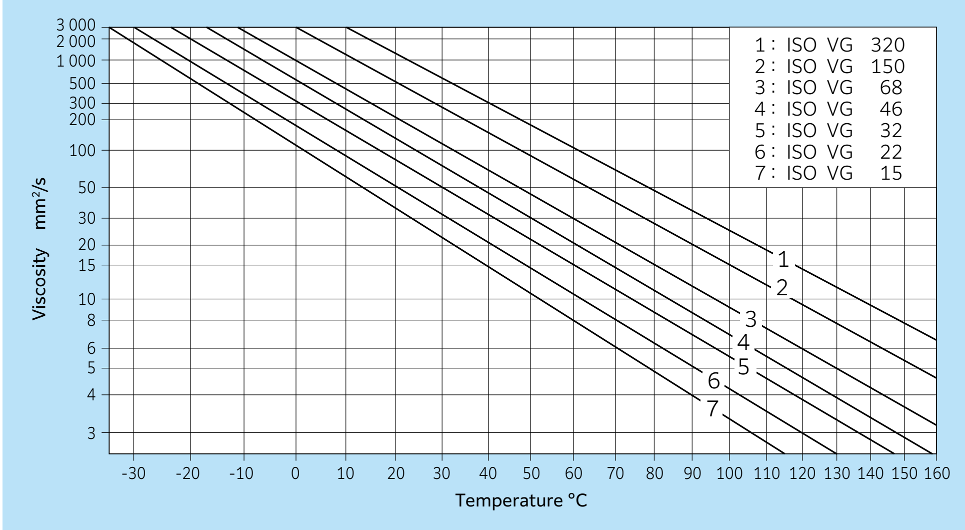

Fig 11.5 Relation between lubricating oil viscosity and temperature

Table 11.9 Standards for lubricating oil viscosity

Bearing operating temperature °C	dn value[1]	Lubricating oil ISO viscosity grade (VG)		Suitable bearing
		Normal load	Heavy load or shock load	
−30 to 0	Up to allowable rotational speed	22, 32	46	All types
0 to 60	Up to 15 000	46, 68	100	All types
	15 000 to 80 000	32, 46	68	All types
	80 000 to 150 000	22, 32	32	All types but thrust ball bearings
	150 000 to 500 000	10	22, 32	Single row radial ball bearings, cylindrical roller bearings
60 to 100	Up to 15 000	150	220	All types
	15 000 to 80 000	100	150	All types
	80 000 to 150 000	68	100, 150	All types but thrust ball bearings
	150 000 to 500 000	32	68	Single row radial ball bearings, cylindrical roller bearings
100 to 150	Up to allowable rotational speed	320		All types
0 to 60	Up to allowable rotational speed	46, 68		Self-aligning roller bearing
60 to 100	Up to allowable rotational speed	150		

1) dn value: [dn = bearing bore diameter d (mm) × rotational speed n (min^{-1})]
Note: 1. Applied when lubrication method is either oil bath or circulating lubrication.
2. Please consult **NTN** Engineering in cases where operating conditions fall outside the range covered by this table.

11.5.2 Oiling amount

When a bearing is to be supplied with oil forcibly, the amount of heat generated from the bearing is equal to the sum of the amount of heat dissipated from the housing and the amount of heat carried away by the oil.

The oiling amount that serves as a rough indication when a standard housing is used can be obtained by formula (11.2).

$$Q = K \cdot q \quad \cdots\cdots (11.2)$$

where,

Q: oiling amount per bearing (cm^3/min)
K: coefficient determined by allowable temperature rise of oil (**Table 11.10**)
q: oiling amount obtained by diagram (cm^3/min) (**Fig. 11.6**)

The heat dissipation amount differs depending on the housing type. Therefore, in the actual operation, it is desirable to obtain the oiling amount suitable for the actual machine by adjusting the amount obtained by formula (11.2) to 1.5 to 2 times.

In addition, when calculating the oiling amount assuming that no heat is dissipated from the housing and the generated heat amount is completely carried away by the oil, use the shaft diameter in the diagram as d = 0.

Table 11.10 Value of K

Expelled oil temp minus supplied oil temp °C	K
10	1.5
15	1
20	0.75
25	0.6

(Example) For tapered roller bearing **30220U** mounted on a flywheel shaft with a radial load of 9.5 kN, operating at 1 800 min^{-1}, what is the amount of lubricating oil Q required to keep the bearing temperature rise below 15°C?

d = 100mm,
$dn = 100 \times 1\,800 = 18 \times 10^4$
From **Fig. 11.6** q = 180cm^3/min
Assume the bearing temperature is approximately equal to the expelled oil temperature,
from **Table 11.10**, since K = 1
$Q = K \times q = 1 \times 180 = 180$cm^3/min

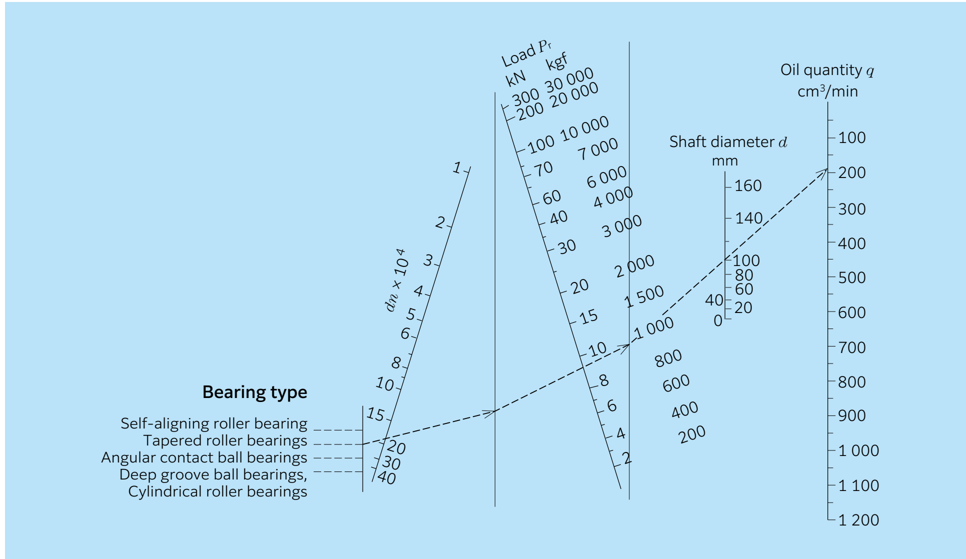

Fig. 11.6 Oil quantity guidelines

11.5.3 Relubrication intervals

The intervals at which lubricating oil should be changed varies depending upon operating conditions, oil quantity, and type of oil used. In general, for oil bath lubrication where the operating temperature is 50°C or less, oil should be replaced once a year. When the operating temperature is between 80°C - 100°C, oil should be replaced at least once every three months. For important equipment, it is advisable that lubricating efficiency and oil purity deterioration be checked regularly to determine when oil replacement is necessary.

12. External bearing sealing devices

External seals have two main functions: to prevent lubricating oil from leaking out of the bearing, and to prevent dust, water, and other contaminants from entering inside the bearing. When selecting a seal, the following factors should be considered, in addition to the application's operating conditions: Type of lubricant (oil or grease), seal lip speed, shaft misalignment, space limitations, seal friction and heat generation, and cost.

Sealing devices for rolling bearings fall into two main classifications: non-contact seals and contact seals.

- **Non-contact seals**: Non-contact seals utilize a small clearance between the shaft and the housing, or between the shaft and sealing apparatus. Therefore friction is negligible, making them suitable for high speed applications.

  In order to improve sealing capability, the gaps between the shaft and sealing apparatus are often filled with lubricant.

- **Contact seals**: A contact seal is a seal in which a molded synthetic rubber lip on a steel plate is pressed against the shaft. Contact seals are generally far superior to non-contact seals in sealing effectiveness, although their friction torque and temperature rise coefficients are higher. Furthermore, because the lip portion of a contact seal slides while in contact with the shaft, the allowable lip speed may vary based on the seal design.

  The surface at which the seal lip contacts the shaft must be lubricated. Ordinary bearing lubricant can also be used for this purpose.

  Table 12.1 lists the special characteristics of seals and other points to be considered when choosing an appropriate seal.

Table 12.1 Seal characteristics and selection considerations

Type	Seal construction	Designation	Seal characteristics and selection considerations
Non-contact seals		**Clearance seal**	This is an simple seal design with a small radial clearance between the shaft and housing.
		**Oil groove seal** (oil grooves on housing side)	Several concentric oil grooves are provided on the housing inner diameter to improve the sealing effectiveness. When the grooves are filled with lubricant, the ingress of external contaminants is prevented.
		**Oil groove seal** (oil grooves on shaft side and housing side)	Oil grooves are provided on both the shaft outer diameter and housing inner diameter for a seal with even greater sealing effectiveness.
		**Axial labyrinth seal**	This seal has a labyrinth passageway on the axial side of the housing.
		**Radial labyrinth seal**	A labyrinth passageway is located on the radial side of the housing. For use with split housings. This offers better sealing effectiveness than axial labyrinth seals.
		**Aligning type labyrinth seal**	The seal's labyrinth passageway is slanted and has sufficient clearance to prevent contact between the housing projections and the shaft, even as the shaft realigns.

Cautionary points regarding selection (clearance seal and oil groove seals)

- In order to improve sealing effectiveness, clearances between the shaft and housing should be minimized. However, care should be taken to confirm shaft/bearing rigidity and other factors to avoid direct contact between the shaft and housing during operation.

Oil groove clearance (approx.)

Shaft diameter mm	Clearance mm
Up to 50	0.2～0.4
50 or larger	0.5～1.0

- Oil groove width, depth (reference)
  Width: 2 to 5 mm
  Depth: 4 to 5 mm
- Three or more oil grooves should be provided.
- Sealing effectiveness can be further improved by filling the oil groove portion with grease of which ASTM worked penetration is 150 to 200.
- Grease is generally used as the lubricant for labyrinth seals, and, except in low speed applications, is commonly used together with other sealing devices.

Cautionary points regarding selection (labyrinth seals)

- In order to improve sealing effectiveness, labyrinth passageway clearances should be minimized. However, care should be taken to confirm shaft/bearing rigidity, fit, internal clearances and other factors to avoid direct contact between labyrinth projections during operation.

Labyrinth clearance (approx.)

Shaft diameter mm	Clearance mm	
	Radial direction	Axial direction
—～ 50	0.2～0.4	1.0～2.0
50～200	0.5～1.0	3.0～5.0

- Sealing effectiveness can be further improved by filling the labyrinth passageway with grease of which ASTM worked penetration is 150 to 200.
- Labyrinth seals are suitable for high speed applications.

External Bearing Sealing Devices

Type	Seal construction	Designation	Seal characteristics and selection considerations
Non-contact seals		**Oil comb sleeve**	In this design, lubricating oil that makes its way out of the housing along the shaft is thrown off by projections on the oil comb sleeve and recirculated.
		**Slinger provided in the housing**	Seal type whereby a slinger is provided in the housing that prevents lubricant from leaking by centrifugal force produced via rotation.
		**Slinger provided outside the housing**	By mounting a slinger on the outside of the housing, centrifugal force helps to prevent dust and other solid contaminants from entering.
Contact seals		**Z grease seal**	In cross section resembling the letter "Z"; this seal's empty spaces are filled with grease. The seal is commonly used with a plummer block (housing).
		**V-ring seal**	This design enhances sealing efficiency with a lip that seals from the axial direction. With the aid of centrifugal force, this seal also offers effective protection against dust, water, and other contaminants entering the bearing. Can be used for both oil and grease lubrication. At seal peripheral speeds in excess of 12 m/s, seal ring fit is lost due to centrifugal force, and a clamping band is necessary to hold it in place.
	  For dust proof  For preventing lubricant leakage	**Oil seal**	Oil seals are widely used, and their shapes and dimensions are standardized under JIS B 2402. In this design, a ring-shaped spring is installed in the lip section. As a result, contact pressure is exerted between the lip edge and shaft surface, and sealing effectiveness is good. When the bearing and oil seal are in close proximity, the internal clearance of the bearing may be reduced by heat produced by the oil seal. In addition to considering the heat generated by contact seals at various peripheral speeds, internal bearing clearances must also be selected with caution. Depending on its orientation, the seal may function to prevent lubricant from leaking out or foreign matter from getting in.

Cautionary points regarding selection (non-contact seals)

- Seal type that utilizes centrifugal force of the slinger mounted on rotating shaft.
- If mounted on the inside of the housing, the slinger should function to seal in lubricant by the centrifugal force produced by rotation.
- If mounted on the outside of the housing, the slinger should function to seal out foreign matter by the fan effect produced by rotation.
- These seal types are commonly employed together with other sealing devices.

Cautionary points regarding selection (oil seal)

Shaft surface roughness (reference)

Peripheral speed m/s	Surface roughness *Ra*	Surface roughness *Rz*
～ 5	0.8	3.2
5～10	0.4	1.6
10～	0.2	0.8

Shaft material (reference)

Material	Machine structural carbon steel Low carbon alloy steel Stainless steel
Surface hardness	HRC 40 or higher necessary HRC 55 or higher advisable
Processing method	Final grinding without repeat (moving), or buffed after hard chrome plating

Allowable speed/temperature according to seal type/material (reference)

Seal type/material		Allowable peripheral speed m/s $\left(v(\text{m/s})=\frac{\pi \times d(\text{mm}) \times n(\text{min}^{-1})}{60\,000}\right)$	Allowable temp °C
Oil seal	Nitrile rubber	16 or below	−25 ～120
	Acrylic rubber	26 or below	−15 ～150
	Fluorinated rubber	32 or below	−30 ～200
Z grease seal	Nitrile rubber	6 or below	−25 ～120
V-ring	Nitrile rubber	40 or below	−25 ～120

External Bearing Sealing Devices

Type	Seal construction	Designation	Seal characteristics and selection considerations
Combination seals		**Z-seal + Labyrinth seal**	This is an example of an axial labyrinth seal which has been combined with a Z seal to increase its sealing effectiveness. The axial labyrinth seal is affixed to the shaft with a setting bolt or other method. In the diagram on the left, both the direction of the Z-seal and the labyrinth seal are oriented to keep dust and other contaminants out of the bearing. Because a Z-seal has been incorporated, the allowable peripheral speed should not exceed 6 m/s.
		**Labyrinth seal + Oil groove seal + Slinger**	This is an example of a combination of three different non-contact seals. It has the advantage of preventing both lubricant leakage from inside the bearing and infiltration of dust and other contaminants from the outside. It is widely used on mining equipment and as a sealing system with plummer blocks in extremely dusty application conditions.
		**Oil groove seal + Slinger + Z-seal**	This is an example where an oil groove seal and slinger have been combined with a Z-seal to increase its sealing efficiency. In the diagram on the left, all three seals have been oriented to keep dust and other contaminants out of the bearing. It is widely used on mining equipment and as a sealing system with plummer blocks in extremely dusty application conditions.

13. Bearing materials

13.1 Raceway and rolling element

While the contact surfaces of a bearing's raceways and rolling elements are subjected to repeated heavy stress, they must also maintain high precision and rotational accuracy.

To accomplish this, the raceways and rolling elements must be made of a material that has high hardness, is resistant to rolling fatigue, is wear resistant, and has good dimensional stability. The most common cause of fatigue in bearings is the inclusion of non-metallic inclusions in the steel. Nonmetallic inclusions contain hard oxides that can cause fatigue cracks. Clean steel with minimal non-metallic inclusions must therefore be used.

All **NTN** bearings use steel that is low in oxygen content and nonmetallic impurities, refined by a vacuum degassing process and outside hearth smelting. For bearings requiring especially high reliability and long life, steels of even higher in purity, such as vacuum melted steel (VIM / VAR) and electro-slag melted steel (ESR), are used.

13.1.1 Raceway and rolling element materials

1) High/mid carbon alloy steel

In general, steel types capable of being **"through hardened"** below the material surface are employed for raceways and rolling elements. Foremost among these is **high carbon chromium bearing steel**, which is widely used. For large type bearings and bearings with large cross sectional dimensions, induction hardened bearing steel is used, which incorporates manganese(Mn) or molybdenum(Mo). Midcarbon chromium steel incorporating silicon(Si) and manganese may also be used, which gives it hardening properties comparable to high carbon chromium steel.

Table 13.1 (A-140) gives the chemical composition of representative high carbon chrome bearing steels that meet JIS G 4805. SUJ2 is frequently used. SUJ3, with enhanced hardening characteristics containing a large quantity of Mn, is used for large bearings. SUJ5 is SUJ3 to which Mo has been added to further enhance hardening characteristics, and is used for oversized bearings or bearings with thick walls.

Table 13.1 (A-140) lists the chemical composition of the primary materials that are equivalent or similar to these JIS high carbon chrome bearing steels. The chemical composition of JIS SUJ2 is nearly equivalent to that of AISI, SAE standard 52100, German DIN standard 100Cr6, and Chinese GB standard GCr15.

2) Carburizing (case hardened) steel

Carburizing hardens the steel from the surface to the proper depth, leaving a relatively soft core. This provides **hardness and toughness**, making the material **suitable for impact loads**. **NTN** uses carburizing (case hardened) steel for most of its tapered roller bearings. In terms of case hardened steel for **NTN**'s other bearings, chromium steel and chrome molybdenum steel are used for small to medium sized bearings, and nickel chrome molybdenum steel is used for large sized bearings. **Table 13.2** (A-141) shows the chemical composition of representative carburizing steels of JIS.

The table lists the chemical composition of similar materials. The chemical composition of JIS SCM420 is nearly equivalent to that of AISI, SAE standard 4118, German DIN standard 20CrMo4 or 25CrMo4. Chinese GB standard has a slightly different amount of Cr and Mo compared with G20CrMo.

3) High temperature capable bearing steel

When bearings made of ordinary high carbon chromium steel which have undergone standard heat treatment are used for long durations at high temperatures, unacceptably large dimensional changes can occur as described in section 13.1.2. For this reason, **a dimension stabilizing treatment** (TS treatment) has been devised for very high temperature applications. This treatment however reduces the hardness of the material, thereby reducing rolling fatigue life. (See section "3.3.2 Bearing characteristics factor a_2" on page A-22.) Note that dimensional changes can occur in normal use too.

Standard high temperature bearings for use at temperatures from **150°C - 200°C**, add silicon to the steel to improve heat resistance. This results in a bearing with excellent rolling fatigue life with minimal dimensional change or softening at high temperatures.

A variety of heat resistant steels are also incorporated in bearings to minimize softening and dimensional changes when used at high temperatures. Two of these are high-speed molybdenum steel and high-speed tungsten steel. For bearings requiring heat resistance in high speed applications, there is also heat resistant case hardened molybdenum steel (see **Table 13.3** on A-142).

4) Corrosion resistant bearing steel

For applications requiring high corrosion resistance, **stainless steel** is used. To achieve this corrosion resistance, a large proportion of the alloying element chrome is added to martensitic stainless steel (**Table 13.4** on A-142).

5) Induction hardened steel

Besides the use of surface hardening steel, induction hardening is also utilized for bearing raceway surfaces, and for this purpose **mid-carbon steel** is mainly used for its lower carbon content instead of through hardening steel.

Table 13.5 (A-142) shows the chemical composition of the primary materials that are similar to the representative medium carbon steels (machine structural carbon steels) of JIS used for small products. For deep hardened layers required for **larger bearings** and **bearings with large surface dimensions, mid-carbon steel is fortified with chromium and molybdenum**.

6) Other bearing materials

For ultra high speed applications and applications requiring very high level corrosion resistance, ceramic bearing materials such as Si_3N_4 are also available.

13.1.2 Properties and characteristics of bearing Materials

1) Physical and mechanical properties of bearing materials (besides resin)

Table 13.6 and **Table 13.7** (A-143) show physical and mechanical properties of the representative materials used for raceways, rolling elements, and cages.

2) Dimensional change of bearings

Dimensions of bearings used for a long time may change depending on the use condition. This phenomenon is called dimensional change.

<Mechanism of dimensional change>

A standard bearing steel structure contains a small amount of austenite in the matrix of hard martensite. This austenite is partially retained austenite without being transformed into martensite in the cooling process of the bearing steel quenching process, and is called residual austenite.

Since the residual austenite is an unstable structure, it is transformed into a stable structure (martensite) when the bearing is being used. This structure transformation is the cause of the dimensional change of bearings.

Fig. 13.1 shows measured values of dimensional change of a standard bearing held at 120°C over an extended period of time.

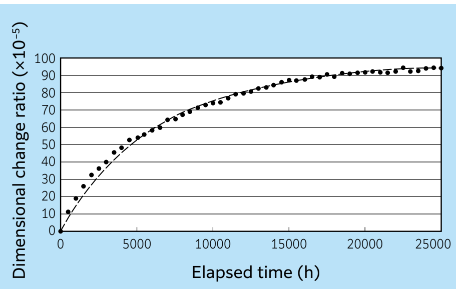

Fig. 13.1 Example of dimensional change rate of standard bearings that are held at 120°C for a long time (measured values)

The dimensional change rate becomes larger as the elapsed time or the temperature of exposure increases.

Depending on the use condition, dimensional change may occur with bearings made of general bearing steel that did not reach 100°C, which is the normal limit.

Bearings that underwent dimension stabilization treatment (TS treatment) have a significantly lower dimensional change. For details, please contact **NTN** Engineering.

<Dimensional change problems and countermeasures>

Among dimensional change, particular attention should be paid to inner ring expansion.
When the inner ring expands by dimensional change, the interference between the inner ring and the shaft decreases, and the bearing may be heavily damaged by creeping or axial movement. Therefore, when a bearing is to be used for a long time, the bearing specifications and fixing method must be determined with the interference decrease due to dimensional change taken into consideration. **For example, the interference can be increased (see section "7. Bearing fits") or fixing in the axial direction can be reinforced (see section "14. Shaft and housing design")**.

<Situations to monitor dimensional change>

The dimensional change of bearings is expressed by the bearing dimension × dimensional change rate. Therefore, under a given temperature and elapsed time, larger bearings show greater dimensional change. Pay particular attention to the amount of dimensional change when large bearings are to be used with fits with small interference.

In addition, dimensional change does not occur during the rotation inspection immediately following bearing installation. It is observed after a long-period operation. Therefore, for machines and parts used for a long time, periodic inspection is effective for preventing problems. For detailed consideration, please consult **NTN** beforehand.

13.2 Cage

Bearing cage materials must have the strength to withstand rotational vibrations and shock loads. These materials must also have a low friction coefficient, be lightweight, and be able to withstand bearing operating temperatures.

13.2.1 Metal materials

For **small** and **medium sized bearings**, pressed steel cages of **cold** or **hot rolled material** with a low carbon content of approx. 0.1% are used. However, depending on the application, **austenitic stainless steel** is also used. Machined cages are generally used for **large bearings**. **Carbon steel for machine structures** or **high-strength cast brass** is frequently used for the cages, but other materials such as **aluminum alloy** are also used. **Table 13.8** and **Table 13.9** (A-143) show the chemical composition of the representative cage materials.

Besides **high-strength brass**, medium carbon **nickel**, **chrome** and **molybdenum steel** that has been hardened and tempered at high temperatures are also used for bearings used in aircraft. The materials are often **plated with silver** to enhance lubrication characteristics.

13.2.2 Resin materials

Recently resin cages are used in place of metals because the material is lightweight and easy to mold into complicated shapes. On the other hand, resins have disadvantages such as lower strength and heat resistance. Therefore, it is important to select resin materials that take advantage of their characteristics. **Table 13.10** (A-144) shows the characteristics of the representative cage resin materials. These materials are rarely used without being filled, and are usually reinforced with glass fiber (GF) or carbon fiber (CF).

[Characteristics of resin materials]

(Advantages)

- Lightweight
- High corrosion resistance
- High self-lubricating performance with less abrasion powder
- Low noise
- Can easily be molded into complicated shapes and various designs
- High productivity

(Disadvantages)

- Lower strength compared with metal
- Lower heat resistance compared with metal
- The strength and elastic modulus largely vary widely with temperature.
- The physical properties (strength) may change when resins are exposed to high temperatures for a long period.
- The strength may deteriorate when resins are exposed to certain types of chemical or oils.
- The thermal expansion coefficient is high, and the dimensional change is larger compared with metal.

<<Polyamide (PA): 66, 46>>

Polyamide is suitable for general cage materials because it is low cost and has high strength, heat resistance, wear resistance, and formability. This material has disadvantages such as high water absorbency, physical property deterioration and dimensional change due to water absorption. On the other hand, water absorption increases flexibility and toughness, enhancing the ease of assembly and shock resistance of cages. However, the physical property (strength) may deteriorate rapidly at high temperatures when polyamide is exposed to lubricating oil containing an S (suflur) type or P (phosphorus) type extreme pressure additive.

Polyamide 66 reinforced with glass fibers is the most used material because it has excellent performance as a cage material.

<<Polyphenylene sulfide (PPS)>>

Polyphenylene sulfide has high heat resistance (continuous operating temperature: 220 to 240°C), chemical resistance, melt fluidity, and formability.

<<Polyetheretherketone (PEEK)>>

Polyetheretherketone has the highest heat resistance among thermoplastic resins (continuous operating temperature: 240 to 260°C). It has excellent self-lubricating performance, shock resistance, and chemical resistance, but it is very expensive. It is mainly used for cages of high-speed bearings for machine tools.

<<Fabric reinforced phenolic resin>>
Phenolic resin is a thermosetting resin. It overcomes the disadvantages of hard and brittle phenolic resin having low shock resistance using fabric reinforcement. It is lightweight and has high lubricity and good mechanical properties. Injection molding cannot be performed because of the thermosetting property, so cages are made by machining. It is mainly used for cages of high-speed angular contact ball bearings for machine tools.

13.3 Rubber seal materials

Synthetic rubbers with high heat resistance and oil resistance are used as materials for seals. Different rubber is used depending on the degree of heat resistance.

Table 13.11 (A-144) shows the representative characteristics of the rubber materials.

<<Nitrile rubber (NBR)>>
Nitrile rubber has high oil resistance, heat resistance, and wear resistance, and is widely used as a general material for seals. The operating temperature range is -20 to 120°C.

<<Acrylic rubber (ACM)>>
Acrylic rubber has high heat resistance and can be used above the application temperature of NBR. It has excellent oil resistance but swells in ester oil. An ester oil resistant grade is also available. The operating temperature range is -15 to 150°C.

<<Fluorinated rubber (FKM)>>
Fluorinated rubber is a rubber material having excellent heat resistance, oil resistance, and chemical resistance. It is deteriorated by amine, so attention needs to be paid when combining fluorinated rubber with urea grease that precipitates amine at high temperatures. The operating temperature range is -30 to 230°C.

13.4 Periphery of bearing (shaft, housing)

Table 13.12 (A-145) and **Table 13.13** (A-145) show physical and mechanical properties of representative materials used for shafts and housings. Heat treatment is applied to bearing materials that are used under large loads. Steel with enhanced bending strength and wear resistance (fretting strength) is used. For such applications, bearing materials (**Table 13.6** and **Table 13.7** on A-143) may also be used as shaft materials.

For housing materials that are used under large loads, heat treatment is applied, and materials with enhanced wear resistance (fretting strength) are used. For lightweight applications, aluminum alloy is widely used.

13.5 NTN bearings with prolonged life

NTN is promoting approaches and research and development from various perspectives with respect to long operating life of bearings. Two examples of approaches for bearing materials and heat treatment, (1) TAB/ETA/EA bearings and (2) FA tapered roller bearings will be introduced in the following sections.

13.5.1 TAB/ETA/EA bearing series

1) Characteristics

(1) Effective for lubrication conditions with foreign matter having high hardness
The main cause of the damage of transmission bearings of automobiles is foreign matter in the lubricating oil. TAB/ETA/EA bearings can be used to prolong the operating life of machines under such contaminated lubricating oil conditions.

(2) High peeling strength
Peeling damage is often caused by deterioration of lubrication conditions during use. The limit life can be prolonged by enhancing the bearing's peeling resistance.

2) Mechanism of prolonged bearing life
Bearing damage is often seen on the raceway surface. By applying heat treatment and selecting appropriate materials, the surface structure has enhanced toughness and improved resilience without impairing the surface hardness. In addition, for tapered roller bearings, crowning is also optimized. These suppress suppresses the occurrence of small cracks that might become the starting point of peeling and damage, prolonging the operating life.

(1) Crack resistance and stress releasing effect
The residual austenite, which is softer than the martensitic parent phase, has an effect of relieving stress concentrations acting on the periphery of the dent formed by foreign matter on the rolling contact surface under lubrication conditions with foreign matter mixed into the oil, thereby suppressing the occurrence of cracks.

As shown in **Fig. 13.2**, all the residual stress on the top surface of the dent part is shifted to the tensile side. The standard heat-treated product of through hardened steel has residual tensile stress. When a specially heat-treated product and a standard heat-treated product are compared, the special heat treated material has less shifting of stresses to the tensile side, which can be harmful, and a stress release action is observed.

(2) Reason for long operating life
ETA and EA bearings have a structure with an appropriate amount of residual austenite and carbide dispersed on the surface region, and the structure is thermally stabilized by the special heat-treatment mentioned above.

The qualities of the material (residual stress, hardness, micro-structure) of a raceway surface generally change due to heat generation and shearing stress action during rolling contact, leading to fatigue cracks. Therefore, improving resistance to temper softening is effective to prevent surface-initiated damage. The residual austenite obtained by ordinary carburizing can suppress generation and progress of cracks and is work-hardened during use (the strength increases). Therefore, by using an appropriate amount of it, the material becomes tough. However, it is unstable against heat. On the other hand, when nitrogen is introduced and diffused under an appropriate condition, a matrix of residual austenite and matensite parent phase that is stable against heat is formed, and the material becomes resilient against quality changes.

3) Supported bearing sizes

Table 13.15

●Deep groove ball series	●Tapered roller series
TAB000 to TAB020	All types that have bearing diameter to be equal to or lower than ϕ600
TAB200 to TAB217	
TAB300 to TAB311	

For other types besides the above, please contact **NTN** Engineering.

Table 13.14 Comparison of dent shapes of each material

Material		Surface hardness [HRC]	Residual austenite amount [%]	Dent diameter [mm]	Dent depth [μm]	Protrusion amount [μm]
Through hardened steel	Standard bearing	62.0	10	2.40	80	5
	TAB bearing	62.0	28	2.45	83	4
Carburizing steel	Standard bearing	61.0	25	2.80	102.5	1
	ETA bearing	62.5	29	2.63	97.5	1

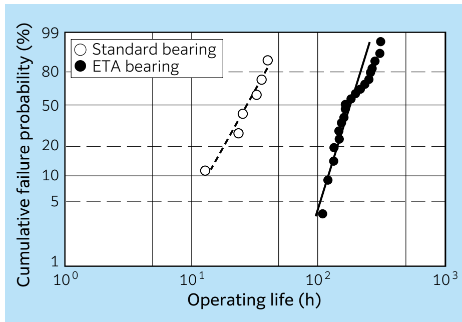

Fig. 13.4 Operating life comparison between ETA tapered roller bearing and standard bearing (mixed with foreign matter)

13.5.2 FA tapered roller bearings

NTN developed special heat treatment (FA treatment) for refining crystal grains of bearing steel to half or less the size of the conventional ones by focusing on refining strengthening of crystal grains. (See **Fig. 13.5**) **NTN** adopted this technique for "FA tapered roller bearings," thereby improving the indentation resistance and realizing long operating life under the lubrication conditions including foreign matter. Further, by combining optimization techniques for the internal bearing design acquired during development of the ECO-Top series, the seizure resistance is improved and the bearing size can be greatly reduced.

Remarks: FA is an abbreviation of fine austenite strengthening treatment.

FA treatment (Fine Austenite Strengthening)

- Longer operating life is realized by crystal grain refinement of bearing steel.
- The crystal grains of bearing steel are refined to half or less the size of the conventional ones.

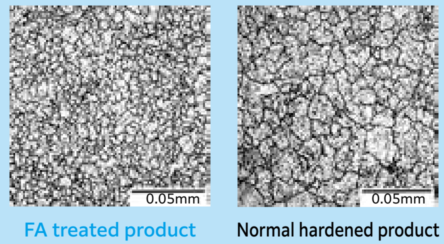

Fig. 13.5 Former austenite crystal grain boundary

1) Longer operating life

- Rolling fatigue life is improved by crystal grain refinement.
- The residual austenite amount is optimized by carbonitriding, and resistance to surface-initiated damage caused by rolling over foreign matter is improved by the crystal grain refinement technique.

- Special crowning that is designed to obtain optimum surface pressure distribution under light to heavy load conditions is adopted.

Thus, the operating life under the lubrication condition including oil types and foreign matter close to the actual machine was greatly extended compared with the standard product.

2) Optimum oil film formation design

The rib area of a tapered roller bearing has sliding contact, and the quality of the oil film forming capability of this area greatly affects the bearing performance.

In the FA tapered roller bearing, the oil film forming capability of the rib area is improved by optimization techniques involving parameters such as the shape, accuracy, and roughness of the contact area of the flange and the roller acquired during ECO-Top bearing development. Thus, the rotational torque is reduced, and the seizure resistance and the preload loss resistance are improved.

3) Seating of assembly width

When a tapered roller bearing is to be used under preload, it is necessary to give sufficient stable rotation to the bearing and bring the bearing into a proper state in which the roller end surface and the inner ring rib surface are brought into contact with each other.

The smaller the number of stable rotations, the more reliably the preload setting can be achieved, and the assembly work becomes more efficient.

With FA tapered roller bearings, preload can reliably be set in a short time by the optimization of the internal bearing design. For example, it may become possible to stop applying gear oil to help achieve early stabilization. The roller becomes stable at a rotation speed equal to that of a conventional bearing by using only rust preventative oil.

4) Improvement in indentation resistance

To make bearings smaller, it is necessary to improve the indentation resistance to prevent safety factor decrease caused by a decrease of the static load rating.

Regarding FA tapered roller bearings, the indentation depth is less than one ten-thousandth of the rolling element diameter even under the static load with a safety factor (S_0) = 0.6.

5) Test data

(1) Operating life

(Condition of linear contact type operating life test)

Test machine : **NTN** linear contact life test machine
Test piece : ϕ12 × L12, R480
The other test piece : ϕ20 Roller(SUJ2)
Load (kN) : 13.74
Contact stress (Mpa) : 4 155 (P_{max})
Lubricating oil : Turbine oil 68

Table 13.19 Result of operating life test under clean lubricating oil condition (Result of comparison test with linear contact type test piece)

Heat treatment method	L_{10} operating life, × 10^4 cycles	L_{10} life ratio
4Top	1 523	1.0
ECO-Top(ETA)	3 140	2.1
FA	4 290	2.8

*L_{10} life ratio is the comparison when 4Top is 1.0.

(Condition of bearing operating life test)

6) Downsizing with FA tapered roller bearing

Improvement in the bearing life, seizure resistance, and indentation resistance strength allows the compact ratio below by adopting an FA tapered roller bearing (**Fig. 13.15**).

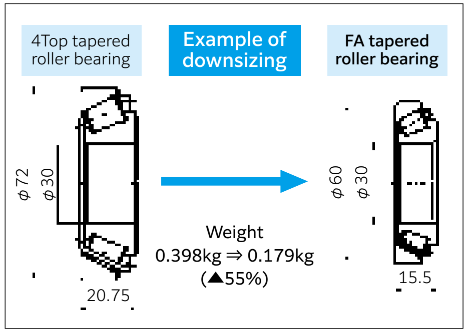

Fig. 13.15 Example of compact ratio

7) Supported bearing size

The target bearings are bearings with an outer diameter of ϕ145 or below. Contact **NTN** Engineering for details.

13.6 Bearing fatigue analysis technique

In a region subjected to plastic deformation due to rolling fatigue, various X-ray analysis parameters obtained by X-ray stress measurements (residual stress, diffraction half-value with, and residual ausentite) may be observed. There is a technique that estimates the degree of progress of rolling fatigue (degree of fatigue) based on the X-ray stress measurement result using this characteristic (**Fig. 13.16**). Since the mid-1980s, **NTN** has been investigating the relationship between the X-ray analysis value (fatigue degree in **Fig. 13.16**) and the life ratio (a value expressed by the percentage of the operating time in which peeling occurred is 100%) for surface-initiated damage (peeling and early peeling starting from dents), which has been frequently observed in the field. Since the relationship changes depending on various rolling conditions (combination of surface roughness, load, and lubrication condition), the values are used for reference; however, the remaining operating life can be estimated by using this relationship diagram.

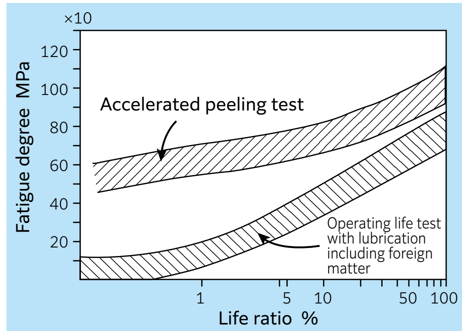

Fig. 13.16 Relationship between degree of fatigue and life ratio

Recently, fatigue degree estimation is being studied using variation in X-ray diffraction ring peak intensity with high sensitivity even in the latter stage of fatigue.

Table 13.9 Chemical composition of high-strength cast brass for machined cages

Standard	Code	Chemical composition (%)							Impurities	
		Cu	Zn	Mn	Fe	Al	Sn	Ni	Pb	Si
JIS H 5120	CAC301	55.0 to 60.0	33.0 to 42.0	0.1 to 1.5	0.5 to 1.5	0.5 to 1.5	Max. 1.0	Max. 1.0	Max. 0.4	Max. 0.1

Table 13.10 Representative characteristics of resins used for cages

		Polyamide		Polyphenylene sulfide	Polyetheretherketone	Fabric-reinforced phenolic resin
		66	46	PPS	PEEK	
Type		Crystalline thermoplastics	←	←	←	Thermosetting resin
Melting point °C		265	295	285	343	—
Glassy-transition temperature °C		66	78	88	143	—
Maximum continuous operating temperature°C		120	150	230	260	—
Price 1 (low) to 5 (high)		1	2	3	5	4
Characteristics	Formability	◎	○	○	○	×
	Toughness	◎	◎	△	○	○ to △
	Strength	○	○	○	◎	△
	Oil resistance	○ to △	○ to △	◎	◎	○
	Moisture/water absorption	Large	Large	Slight	Slight	Small
Comprehensive evaluation		The property is generally stable.	The formability is slightly poor compared with polyamide 66, but the heat resistance is high.	The water absorbency is low, and the oil resistance and heat resistance are high.	Polyetheretherketone has properties necessary for cages but is expensive.	The lubricity is high, but complicated shapes cannot be machined.
Applications		All-purpose	Temperature higher than polyamide 66	Applications that require oil resistance and heat resistance higher than polyamide	High-speed bearings for high-temperature and high-speed machine tools	High-speed angular contact ball bearings for machine tools

Note: ◎ Excellen ○ Good △ OK × Poor

Table 13.11 Representative characteristics of rubber materials used for seals

Rubber type		Nitrile rubber	Acrylic rubber	Fluorinated rubber
Abbreviation		NBR	ACM	FKM
Characteristics	Elongation	○	○	△
	Compression set	◎	×	○
	Wear resistance	◎	○	◎
	Aging resistance	○	◎	◎
	Weather and ozone resistance	△	◎	◎
	Water resistance	◎	△	◎
	Operating temperature range °C	−20 to 140	−15 to 150	−30 to 230
Comprehensive evaluation		The oil resistance, heat resistance, and wear resistance are high. It is widely used as rubber seals.	It is used at application temperature higher than that of NBR. It is easily swollen in ester oil. An ester-oil resistant grade is also available.	It is expensive. It has excellent heat resistance and chemical resistance but easily affected by urea grease.

14. Shaft and housing design

Depending upon the design of a shaft or housing, the shaft may be influenced by an unbalanced load or other factors which can then cause large fluctuations in bearing efficiency. For example, depending on the dimensional accuracy and shape accuracy of the shaft and housing, there could be insufficient interference fit with the bearing, leading to material creep during operation. When the machining accuracy of the shaft or the housing is insufficient or when there is an error in the installation, the inner ring or the outer ring of the bearing can become misaligned. Operation under this condition may cause excessive loading at the edges of the inner and outer rings as well as rolling elements, deteriorating the fatigue life. Furthermore, chipping damage may occur on the flange face of roller bearings due to heavy contact with the rolling element end surface while operating under misalignment. A speed deferential between the rolling elements and cage may apply abnormal force to the cage, causing damage. For this reason, it is necessary to pay attention to the following when designing shaft and housing:

(1) Bearing arrangement; most effective fixing method for bearing arrangement.
(2) Selection of shoulder height and fillet radius of housing and shaft.
(3) Shape precision and fitting dimensions; runout tolerance of shoulder area.
(4) Machining precision and mounting error of housing and shaft suitable for allowable alignment angle and permissible misalignment of bearing.

When the housing rigidity is insufficient, excessive deformation of the inner and outer rings may lead to poor distribution of loading among rolling elements, causing abnormal noise and deterioration of fatigue life. Therefore, the housing requires sufficient rigidity.

When two or more bearings are to be attached to a shaft, one typically serves as a fixed end bearing and the other serves as a floating end bearing to compensate for axial mounting error and allow for thermal expansion. In addition, when two or more bearings are to be attached to a housing, the design must allow through hole machining to improve the accuracy of the housing.

14.1 Fixing of bearings

When a bearing that receives axial loads and preloads is to be attached to a shaft or a housing, an axial fixing method that is sufficient to withstand the axial loading such as a tightening nut, bolts, or snap rings should be selected because a serious problem may be caused when the raceway moves in the axial direction.

In addition, solid type needle roller bearings (with inner ring) and cylindrical roller bearings (NU and N types) that are to be mainly used as floating side bearings also need to be fixed in the axial direction because the raceway may move in the axial direction when the shaft is bent by a moment load, damaging the bearing.

Table 14.1 shows general bearing fixing methods, and **Table 14.2** shows fixing methods for bearings with tapered bores. See section "15. Bearing handling" for more information about bearing installation and removal.

Table 14.1 General bearing fixing methods

Inner ring clamp	Outer ring clamp	Snap ring
		The most common method of fixing bearings in place is to use clamping nuts or bolts to hold the shaft or housing abutment against the ring end face. The tightening nuts and bolts must be fixed so that they will not be loosened by axial loads or vibration when the bearing is being used.		Use of snap rings regulated under JIS B 2804, B 2805, and B 2806, makes for a very simple construction. However, interference with chamfers, bearing installation dimensions, and other related specifications must be considered carefully. Snap rings are not suitable for applications requiring high accuracy or where the snap ring receives large axial loads.

Table 14.2 Fixing methods–bearings with tapered bores

Adapter sleeve mounting	Withdrawal sleeve mounting	Split ring mounting
		When installing bearings on cylindrical shafts, adapter sleeves or withdrawal sleeves can be used to fix bearings in place axially. The adapter sleeve is fastened in place by frictional force between the shaft and inner diameter of the sleeve.		For installation of tapered bore bearings directly on tapered shafts, the bearing is held in place by a split ring inserted into a groove on the shaft, and is fixed in place with a split ring nut or screw.

14.2 Bearing fitting dimensions

14.2.1 Abutment height and fillet radius

The shaft and housing **abutment height** (h) should be **larger than the bearings' maximum allowable chamfer dimensions** ($r_{s\ max}$), such that the abutment directly contacts the flat part of the bearing end face. The **fillet radius** (r_a) must be **smaller than the bearing's minimum allowable chamfer dimension** ($r_{s\ min}$) so that it does not interfere with bearing seating.

Table 14.3 lists abutment height (h) and fillet radius (r_a). For bearings to be subjected to very large axial loads, shaft abutments (h) should be higher than the values in the table.

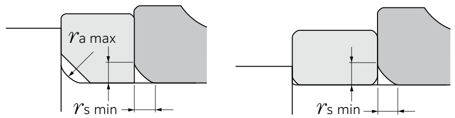
9.5	8	22	20
12	10	27	24
15	12	32	29
19	15	42	38

1) If a bearing supports a large axial load, the height of the shoulder must exceed the value given here.
2) Used when an axial load is light. These values are not suitable for tapered roller bearings, angular ball bearings and spherical roller bearings.
Note: $r_{as\ max}$ indicates maximum allowable fillet radius.

14.2.2 For spacer and ground undercut

In cases where a fillet radius ($r_{a\ max}$) larger than the bearing chamfer dimension is required to strengthen the shaft or to relieve stress concentration (**Fig. 14.1a**), or abutment height is too low to afford adequate contact surface with the bearing (**Fig. 14.1b**), the use of a spacer may be beneficial.

Relief dimensions for ground shaft and housing fitting surfaces are given in **Table 14.4**.

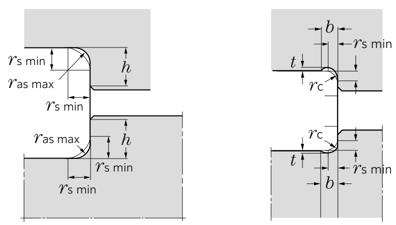


(a) (b)

Fig. 14.1 Bearing mounting with spacer

Table 14.4 Relief dimensions for ground shaft

$r_{s\ min}$	Relief dimensions		
	b	t	r_c
1	2	0.2	1.3
1.1	2.4	0.3	1.5
1.5	3.2	0.4	2
2	4	0.5	2.5
2.1	4	0.5	2.5
2.5	4	0.5	2.5
3	4.7	0.5	3
4	5.9	0.5	4
5	7.4	0.6	5
6	8.6	0.6	6
7.5	10	0.6	7



14.2.3 Fitting dimensions for thrust bearings

For thrust bearings, it is necessary to make the raceway washer back face sufficiently wide in relation to load and rigidity. Consequently, fitting dimensions from the dimension tables should be adopted. (**Figs. 14.2** and **14.3**)

For this reason, **shaft and abutment heights will be larger than for radial bearings**. (Refer to dimension tables for all thrust bearing fitting dimensions.)

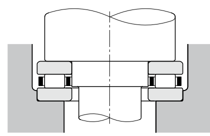


Fig. 14.2

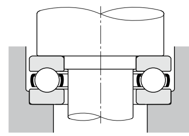

Fig. 14.3

14.3 Shaft and housing accuracy

Table 14.5 shows the required accuracies for shaft and housing fitting surface dimensions and configurations, as well as fitting surface roughness and abutment squareness for normal operating conditions.

Table 14.5 Shaft and housing accuracy

Concern		Shaft	Housing
Dimensional accuracy		IT6 (IT5)	IT7 (IT5)
Roundness (max.) Cylindricity		IT3	IT4
Abutment squareness		IT3	IT3
Fitting surface roughness Ra	Small size bearings	0.8	1.6
	Mid-large size bearings	1.6	3.2

Note: For precision bearings (P4, P5 accuracy), it is necessary to improve the circularity and cylindricity accuracies in this table to approximately 50% of these values. For more specific information, please consult the **Precision rolling bearing catalog (CAT. No. 2260/E).**

14.4 Bearing permitted inclination/ allowable alignment angle

A certain amount of misalignment of a bearing's inner and outer rings occurs as a result of shaft flexure, shaft or housing finishing irregularities, and minor installation error. In situations where the degree of misalignment is liable to be relatively large, **self-aligning ball bearings, spherical roller bearings**, **bearing units** and other bearings with aligning characteristics are advisable. Although permitted inclination and allowable alignment angle will vary according to bearing type, load conditions, internal clearances, etc., **Table 14.6** lists some general misalignment standards for normal applications. In order to avoid shorter bearing life and cage failure, it is necessary to maintain levels of misalignment below these standard levels.

See section 3.7 (A-29) for the relationship between "Inclination angle (installation error) and life."

Table 14.6 Bearing types and allowable misalignment/allowable alignment angle

Allowable misalignment			
Deep groove ball bearings	1/1 000 to 1/300	Tapered roller bearings [1]	
Angular ball bearings [1]		Single row standard	1/2 000
Single row	1/1 000	Single row ULTAGE	1/600
		Needle roller bearings	1/2 000
Cylindrical roller bearings			
Bearing series 10, 2, 3, 4	1/1 000		
Bearing series 22, 23	1/2 000		
ULTAGE	1/500		
Double row [2]	1/2 000		

1) The allowable misalignment of combined bearings is influenced by the load center position, so please consult **NTN** Engineering.
2) Does not include high precision bearings for machine tool main shaft applications.
Note: For thrust bearings, please contact **NTN** Engineering.

Allowable alignment angle				
Self-aligning ball bearings	Normal load	1/15	Thrust spherical roller bearings	
			Normal load	1/60 to 1/30
			Bearing units [3]	1/60 to 1/30
Self-aligning roller bearings	Normal load or more	1/115		
	Light load	1/30		

3) For bearing units, see section "F. Bearing units" on page F-12.

15. Bearing handling

15.1 General information

Bearings are precision parts and in order to preserve their accuracy and reliability, care must be exercised in their handling. In particular, bearing cleanliness must be maintained, sharp impacts avoided, and rust prevented.

Bearings are vulnerable to impact. Do not hit them with a hammer directly or drop them on the floor. (**Fig. 15.1**)

In addition, bearings are sensitive to foreign particle contamination. When foreign particles enters the bearing during rotation, denting and/or scratches may occur, resulting in objectionable noise and vibration levels and rough bearing rotation (**Fig. 15.2**). Therefore, when handling bearings, it is necessary to keep the periphery clean.

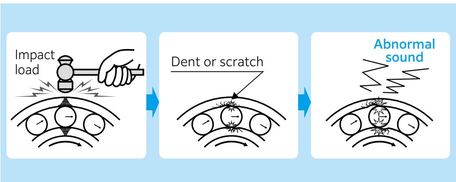

Fig. 15.1 Damage caused by impact

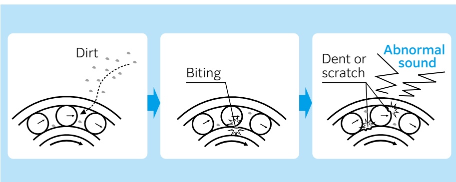

Fig. 15.2 Damage caused by foreign particle contamination

For optimal bearing performance, proper bearing handling methods must be used. The handling methods described herein are general guidelines. Depending on the type and size of bearing needed, special handling "methods" may be necessary. For more detailed information, please consult **NTN** Engineering.

Using proper protective equipment and tools are also essential when installing or removing bearings, to avoid damage to the machinery and ensure the safety of the technician. Further information on proper installation and removal procedures is detailed in the following sections.

15.2 Bearing storage

Most rolling bearings are coated with a rust preventive oil before being packed and shipped. Please observe the following guidelines when storing bearings.

1. Ideally, bearings should be stored indoors at room temperature with a relative humidity of less than 60%. Avoid places in direct sunlight or in contact with outer walls because excessive temperature fluctuation or humidity rise may cause condensation.
2. Bearings should not be stored directly on the ground. Instead, they should be placed on a shelf or pallet at least 20 cm above the ground. The maximum number of shipping boxes to be stacked for storage should limited to four whenever possible (**Fig. 15.3**).
3. Precision rolling bearings, large rolling bearings and thin ring or race rolling bearings must be laid down horizontally for storage (**Fig. 15.4**). Storing them standing vertically may cause raceway deformation.

   To avoid damage during transportation such as fretting or false brinelling, ensure that the individual bearing boxes are packed laying down horizontally within the shipping box. Fill remaining space with dunnage(**Fig. 15.5**).

   Some products have a ↑ symbol on the shipping box to prevent improper storage placement. Follow the indication on the box in this case (**Fig. 15.6**).

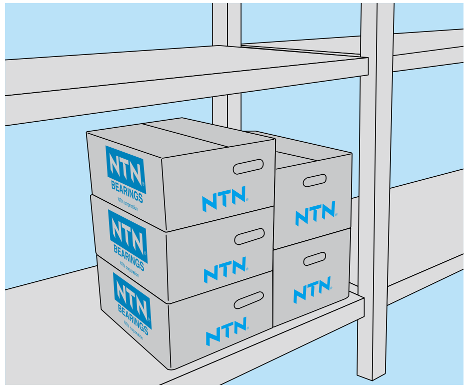

Fig. 15.3 Storing bearings on a shelf

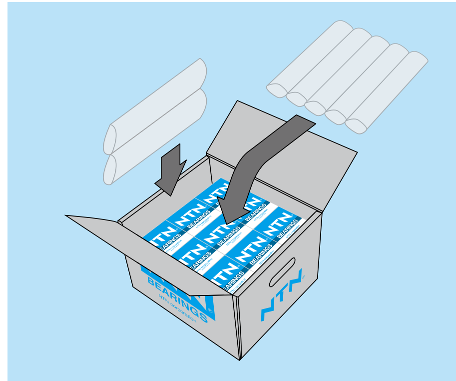

Fig. 15.5 Transportation and storage by shipping box

Fig. 15.4 Storing one-bearing boxes on a shelf

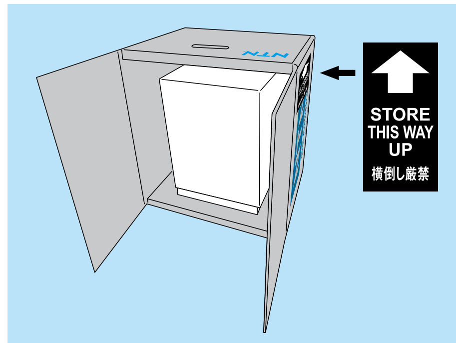

Fig. 15.6 Horizontally placing box prohibited

15.3 Bearing installation

A jig, a measuring instrument, a lubricant, and a clean and dry workshop will be needed for bearing installation. Further, if possible, it is desirable to install miniature/small ball bearings and precision rolling bearings in a clean room because intrusion of dirt and foreign matter significantly affects bearing performance.

Improper installation of bearings may cause marks from the rolling elements on the raceways, adversely affecting the bearing life. For the recommendations on machining accuracy and mounting accuracy of bearings, shafts, and housings, see section "14. Design of shafts and housings."

15.3.1 Installation preparations

(1) Fitting surface of shafts and housings

When a bearing is installed on a shaft or in a housing with surfaces containing burrs or dents, the bearing may not seat properly, causing vibration and noise during operation (see **Figs. 15.7** and **15.8**).

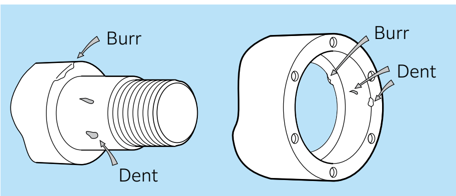

Fig. 15.7 Burrs and dents

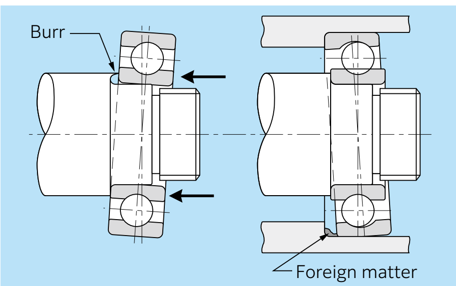

Fig. 15.8 Example of improper bearing installation

Therefore, before mounting bearings, remove any burrs, raised material near dents, rust, or dirt on the shaft, housing, or accessories. (**Fig. 15.9**)

The shaft and housing fitting surfaces should also be checked for roughness, dimensional and design accuracy, and to ensure that they are within allowable tolerance limits. Further, when the bearing is to be press-fitted, using an anti-fretting agent on the fitting surface improves the ease of assembly.

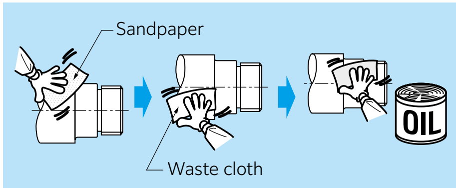

Fig. 15.9 Example of working procedure

(2) Mounting jig

The jig to be used for mounting must have a size suitable for the bearing and be free of dirt or damage.

(3) Opening of bearing

Bearings should be unpackaged directly before use to avoid introducing foreign particle contaminates or condensation which would lead to rust. Gloves should also be worn when handling bearings to avoid rust generation.

(4) Removal of rust preventative oil

In general, bearings with grease lubrication may be installed without cleaning the rust preventative oil.

However, for bearings using oil lubricant, or when lubrication efficiency would be compromised by mixing the grease and rust preventive oil, the rust preventive oil should be removed by washing with a cleaning solvent and dried before installation. The shield type bearings and the seal type bearings filled with grease must not be cleaned.

15.3.2 Installing cylindrical bore bearings

15.3.2.1 Press-fitting

Press-fitting is the most common mounting method and is widely used for small bearings small bearings. Bearings having a relatively small interference can be press-fitted by using a sleeve and applying force to the raceway at room temperature.

When press-fitting a bearing by applying impact with a hammer, use a resin or copper hammer rather than an iron one. To uniformly press the bearing onto the shaft or into the housing, use a sleeve. (Use of a mounting tool kit as shown in **Fig. 15.40**, A-168 is recommended.) Do not directly apply impact to bearing rings or press-fit them by using a punch because the bearings will not be press-fitted uniformly, causing bearing damage (**Fig. 15.10**).

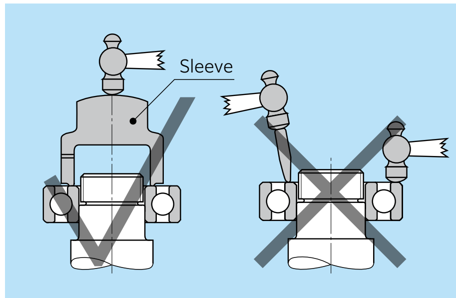

Fig. 15.10 Using hammer for press-fitting

When a large number of bearings are to be installed at one time, a dedicated jig or a hydraulic press may be used.

(1) Press-fitting bearing into shaft

Uniformly apply force by applying a sleeve to the inner ring width surface when press-fitting a bearing onto a shaft. Do not apply force to the outer ring as this will transfer the press force through the rolling elements which may cause dents or scratches on the raceway surface (**Fig. 15.11**).

When press-fitting self-aligning bearings, using a ring-shaped block as shown in **Fig. 15.13** improves ease of installation.

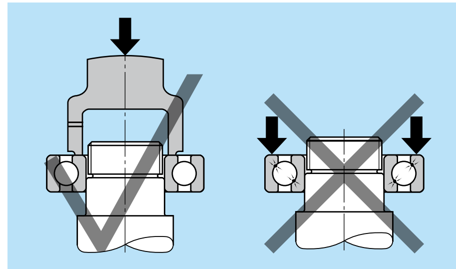

Fig. 15.11 Press-fitting bearing into shaft

(2) Press-fitting bearing into housing

Uniformly apply force by applying a sleeve to the outer ring width surface to press-fit a bearing into a housing. Do not apply force to the inner ring as this will transfer the press force through the rolling elements which may cause dents or scratches on the raceway surface (**Fig. 15.12**).

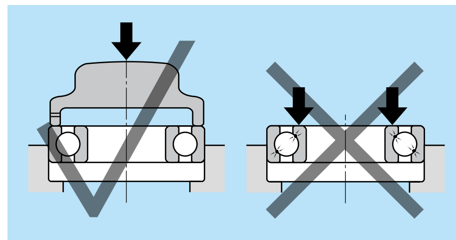

Fig. 15.12 Press-fitting bearing into housing

(3) Simultaneous press-fitting

When press-fitting a non-separable bearing such as a deep groove ball bearing onto the shaft and into the housing at the same time, use a ring-shaped block and uniformly apply force to inner and outer rings simultaneously. Do not apply force on either the inner or outer ring individually because it may cause dents or scratches on the raceway surface (**Fig. 15.13**).

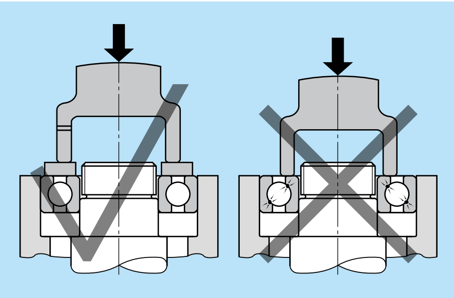

Fig. 15.13 Simultaneous press-fitting

[Caution]

- Excessive interference during installation may cause cracks and excessively small bearing internal clearance, resulting in seizure. For further detail, see section "7. Bearing fits."
- Excessive impact at the time of installation may cause dents and damage.
- No foreign matter should enter the fitting surface during installation.
- For large interference fits and medium/large size bearings, consider other installation methods besides press-fitting at room temperature.

15.3.2.2 Heat fitting (shrink fitting)

When the inner ring interference is large or the bearing is large, press-fitting the inner ring onto the shaft at room temperature requires significant force. Heating the bearing and expanding the inner ring before installation makes the installation onto the shaft easier.

The inner ring expansion amount necessary for heat fitting can be obtained from the interference of the fitting surface between the inner ring and the shaft and the temperature difference before and after the bearing is heated (**Fig. 15.14**).

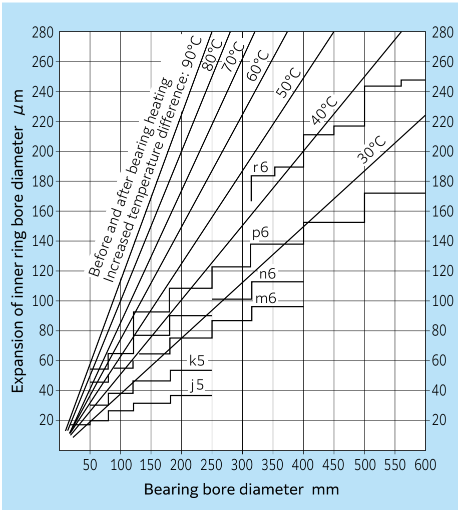

Fig. 15.14 Temperature required for heat-fitting inner ring

Commentary
Bearing Handling
NTN

For heat fitting, any bearing that did not undergo dimension stabilization treatment **must not be heated above 120°C** to avoid permanent bearing damaged and shortened operating life. For sealed bearings, the seal temperature rating must not be exceeded.

In addition, **heat torches and heat guns should not be used for heating bearings** because the bearings may be heated non-uniformly and temperature control is difficult (**Fig. 15.15**).

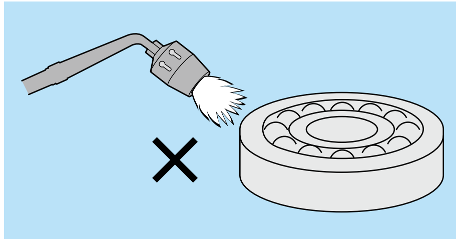

Fig. 15.15 Heating bearings by heat torch

The main methods used to heat bearings uniformly are (1) oil bath, (2) constant temperature oven, and (3) fast therm induction heater.

(1) Heating bearings in oil bath

One bearing heating method is immersing a bearing in a heated clean oil (**Fig. 15.16**). **Foreign particles are often found on the bottom of the oil bath; therefore, do not directly place bearings on the bottom of the oil bath. Instead, place the bearings on a wire rack or suspend it in the oil and then heat it. Shielded bearings and sealed bearings filled with grease must not be heated in the oil bath** (**Fig. 15.17**).

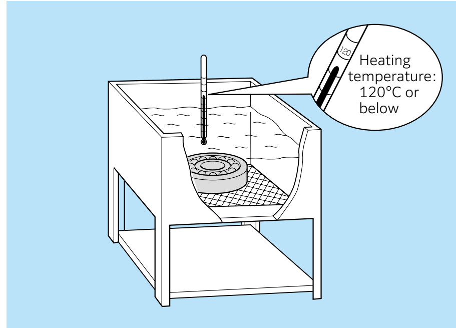

Fig. 15.16 Heating bearings in oil bath

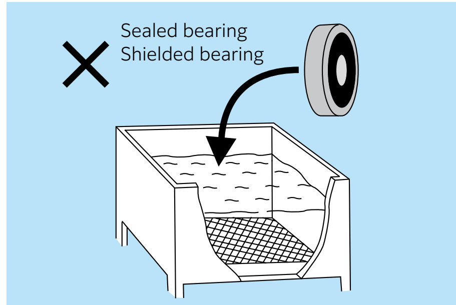

Fig. 15.17 Heating grease filled bearings in oil bath prohibited

(2) Heating bearings in constant temperature oven

With a constant temperature oven, bearings can be heated in a dry state (**Fig. 15.18**).

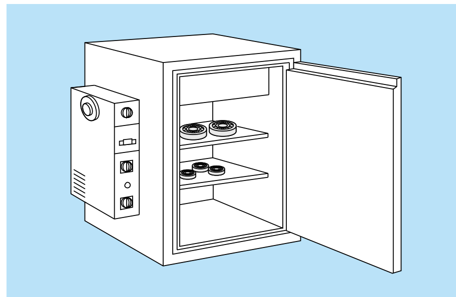

Fig. 15.18 Heating bearings in constant temperature oven

(3) Heating bearings with fast therm induction heater

With a fast therm induction heater, bearings can be heated safely, cleanly, and quickly in a dry state. Heating bearings by induction heating makes the bearings magnetic; therefore, it is necessary to demagnetize bearings after heating. The **NTN** fast therm induction heater (**Fig. 15.42**, A-168) has an automatic demagnetization function.

[Caution]

- Use heat-resistant gloves for safety when handling a heated bearing. **NTN** heat-resistant gloves optimal for bearing handling are available (**Fig. 15.43**, A-168).
- It is important to complete heat fitting quickly. If the bearing cannot be inserted onto the shaft during heat fitting, stop the process and consider removing the bearing.
- When heat fitting is performed, the inner ring contracts in the axial direction during cooling, creating a clearance between the bearing and the shaft shoulder (**Fig. 15.19**). Therefore, it is necessary to tighten the bearing with a nut until it is completely cooled or apply a force in the axial direction while the bearing cools, to bring the bearing into close contact with the shoulder of the shaft.

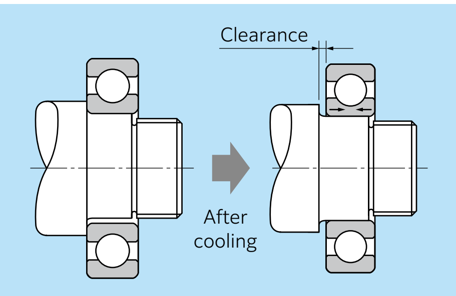

Fig. 15.19 Bearing contraction after heating

15.3.3 Installation of tapered bore bearing

Small tapered bore bearings are installed by inserting a bearing a predetermined amount with locknuts and by using a tapered bore or an adapter sleeve/withdrawal sleeve. Locknuts are tightened by a hook spanner wrench (**Fig. 15.20**).

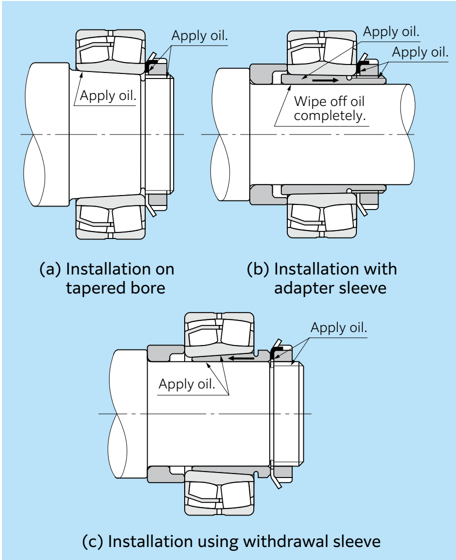

Fig. 15.20 Installation methods using locknuts

Large size bearings require considerable fitting force and must be installed hydraulically.

In **Fig. 15.21** the fitting surface friction and nut tightening torque needed to install bearings with tapered bores directly onto tapered shafts are decreased by injecting high pressure oil between the fitting surfaces.

Commentary
Bearing Handling
NTN

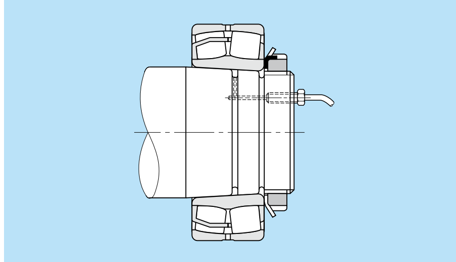

Fig. 15.21 Bearing installation using oil pressure

Fig. 15.22 (a) shows a method of installation where a hydraulic nut is used to drive the bearing onto a tapered shaft. **Fig. 15.19 (b)** and **(c)** show installation methods using a hydraulic nut with adapter sleeves and withdrawal sleeves.

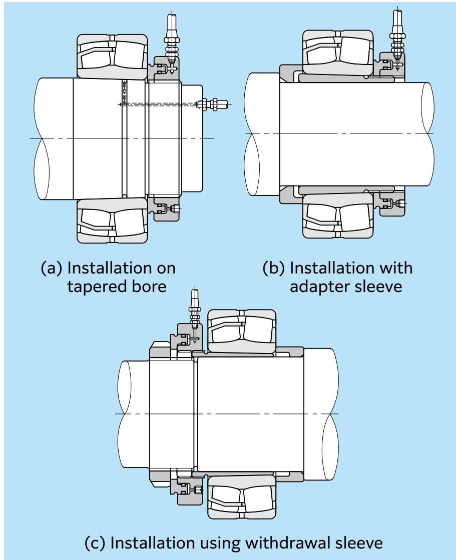

Fig. 15.22 Installation using hydraulic nut

Fig. 15.23 shows an installation method using a hydraulic withdrawal sleeve.

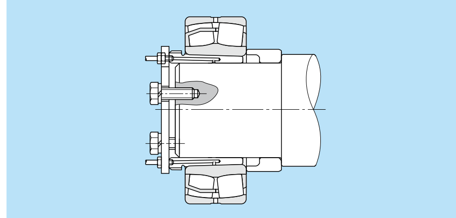

Fig. 15.23 Installation using hydraulic withdrawal sleeve

With tapered bore bearings, as the inner ring is driven axially onto the shaft, adapter or withdrawal sleeve, the interference increases so that the bearing radial internal clearance will decrease. Interference can be estimated by measuring the decrease in radial internal clearance. As shown in **Fig. 15.24**, the radial internal clearance between the rollers and outer ring of spherical roller bearings should be measured with a thickness gauge under no load while the rollers are held in the correct position. Measure the radial internal clearance on both rows, and check that the values are equivalent. Instead of using the decrease in amount of radial internal clearance to estimate the interference, it is possible to estimate the mounted radial internal clearance by measuring the distance the bearing has been driven onto the shaft.

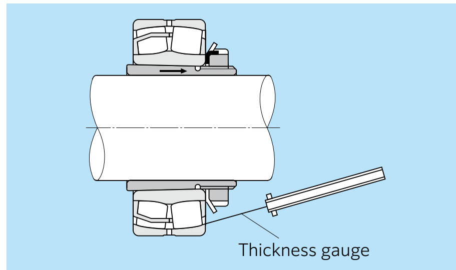

Fig. 15.24 Internal clearance measurement method for spherical roller bearings

For spherical roller bearings, **Table 15.1** (applied to ULTAGE series) and **Table 15.2** (applied to other bearings besides ULTAGE series) indicates the predetermined interference which will be achieved as a result of the radial internal clearance decrease, or the distance the bearing has been driven onto the shaft.

For conditions such as heavy loads, high speeds, or when there is a large temperature differential between inner and outer rings, etc. which require large interference fits, bearings with a minimum radial internal clearance of C3 or greater should be used. **Table 15.1** and **Table 15.2** list the maximum values for radial internal clearance decrease and axial displacement. The remaining clearance in mounted bearings with tapered bores must be greater than the minimum allowable residual clearance listed in **Table 15.1** or **Table 15.2**.

For self-aligning ball bearings, a predetermined interference can be obtained by tightening the nut until the radial internal clearance becomes about half the size before the fitting. After installation, check that the bearing lightly and smoothly rotates.

Note: The nut rotation angle may only be applied when a nut having the same inner diameter code as the bearing is used.

15.3.4 Installation of outer ring

With tight interference fits, the outer rings of small type bearings can be installed with a hydraulic press at room temperature. Alternately, the housing can be heated and expanded before installing the outer ring, or the outer ring can be cooled with a freezer, etc. before installing. If a freezer or another cooling agent is used, moisture will condense on bearing surfaces. Therefore appropriate rust preventative measures are necessary before cooling the bearing.

15.3.5 Internal clearance adjustment

As shown in **Fig. 15.25**, for angular contact ball bearings and tapered roller bearings the required amount of axial internal clearance can be set at the time of installation by tightening or loosening the adjustment nut.

To adjust the suitable axial internal clearance or amount of bearing preload, the internal clearance can be measured while tightening the adjusting nut as shown in **Fig. 15.26**. Another method is to check rotational torque by rotating the shaft or housing while adjusting the nut.

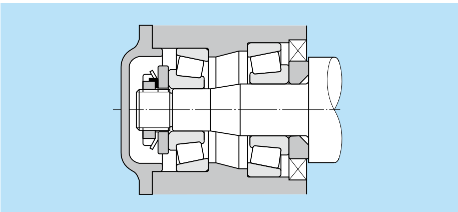

Fig. 15.25 Axial internal clearance adjustment

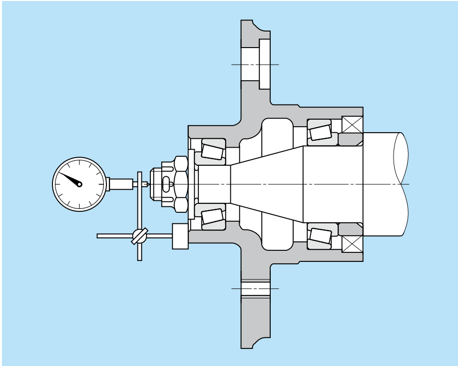

Fig. 15.26 Axial internal clearance measurement

A shim with appropriate thickness may also be used for adjusting the bearing internal clearance. **Fig. 15.27** shows the case in which angular contact ball bearings are used in a face-to-face arrangment on the fixed side. A shim is inserted between the housing front cover and the housing shown by an arrow to change the fixed position of the outer ring.

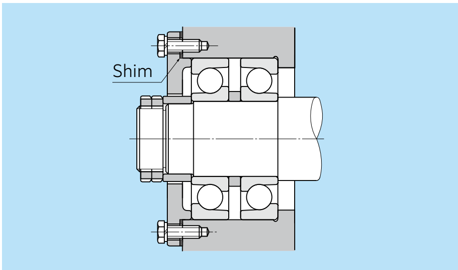

Fig. 15.27 Internal clearance adjustment using shims

15.4 Lubricant enclosure

An appropriate amount of lubricant that is suitable for the use condition of the bearing should be applied if the bearings are not pre-filled with grease. For details, see section "11. Lubrication."

15.5 Post installation running test

To check that the bearing has been properly installed, a running test is performed after installation is completed. The shaft or housing is first rotated by hand and if no problems are observed at low speed, a no-load power test should then be performed. **If no abnormalities are observed, the load and speed are gradually increased to operating conditions. During the test if any unusual noise, vibration, or temperature rise is observed, the test should be stopped and the equipment should be examined. If necessary, the bearing should be disassembled for inspection.**

15.6 Bearing disassembly

Bearings are often removed as part of periodic inspection procedures or during the replacement of other parts. However, the shaft and housing are almost always reinstalled, and in more than a few cases the bearings themselves are reused. These bearings, shafts, housings, and other related parts must be designed to prevent damage during disassembly procedures, and the proper disassembly tools must be employed. When removing bearing rings with interference, pulling force should be applied to the press fit bearing ring only. Do not remove the raceway through the rolling elements.

[Caution]
Bearings and jigs used for disassembly may fall off when the bearing is removed from the shaft or the housing.

15.6.1 Disassembly of bearings with cylindrical bores

For small sized bearings, pullers shown in **Fig. 15.28 (a)** and **(b)** or the press method shown in **Fig. 15.29** can be used for disassembly. When used properly, these methods can improve disassembly efficiency and prevent damage to bearings.

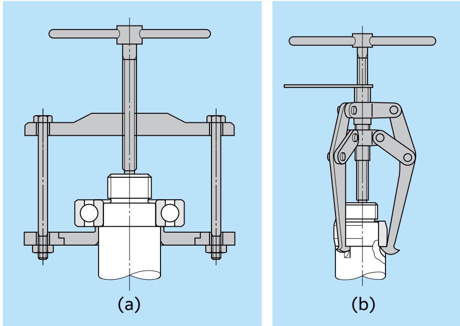

Fig. 15.28 Puller disassembly

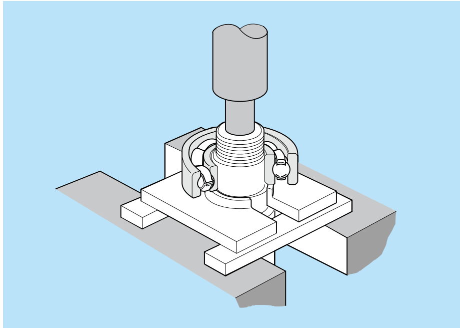

Fig. 15.29 Press disassembly

To facilitate disassembly procedures, attention should be given to planning the designs of shafts and housings, such as providing extraction grooves on the shaft and housing for puller claws as shown in **Figs. 15.30** and **15.31**. Threaded bolt holes could also be provided in housings to facilitate the pressing out of outer rings as shown in **Fig. 15.32**.

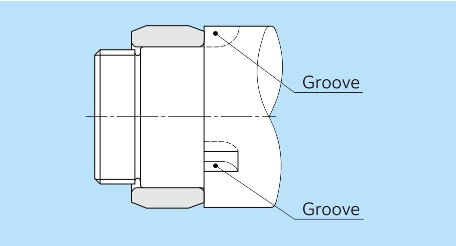

Fig. 15.30 Extracting grooves (example of three positions in circumferential direction)

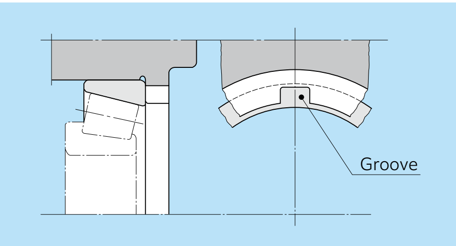

Fig. 15.31 Extraction groove for outer ring disassembly

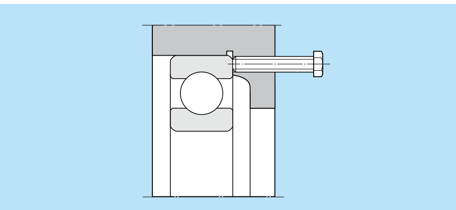

Fig. 15.32 Outer ring disassembly bolt

Large bearings, installed with tight fits, that have been in service for a long period of time, will likely have developed fretting on fitting surfaces and will require considerable dismounting force. In such instances, dismounting friction can be reduced by injecting oil under high pressure between the shaft and inner ring surfaces as shown in **Fig. 15.33**.

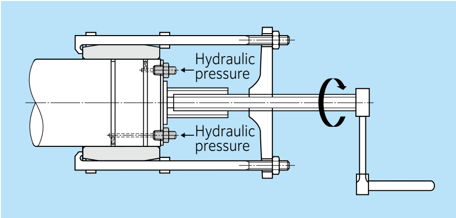

Fig. 15.33 Removal of bearing by hydraulic pressure

Induction heating can be used for removing the inner ring of cylindrical roller bearings having no flange on the inner ring such as NU type and NJ type bearings. With this method, the inner ring is heated until it expands, and can be removed (**Fig. 15.34**).

The bearing becomes magnetized by induction heating; therefore, it is necessary to demagnetize the bearing after heating.

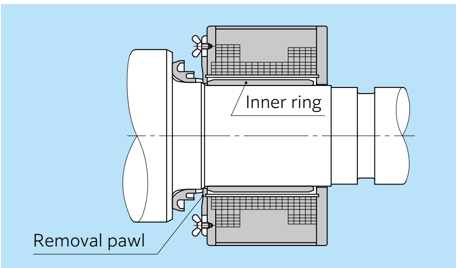

Fig. 15.34 Removal by induction heating

15.6.2 Disassembly of bearings with tapered bores

Small bearings installed using an adapter are removed by loosening the locknut, placing a block on the edge of the inner ring as shown in **Fig. 15.35 (a)** or the edge of the lock nut as shown in **Fig. 15.35 (b)**, and tapping it with a hammer. In such a case, use a resin or copper hammer instead of an iron one. Bearings which have been installed with withdrawal sleeves can be disassembled by tightening down the lock nut as shown in **Fig. 15.36**.

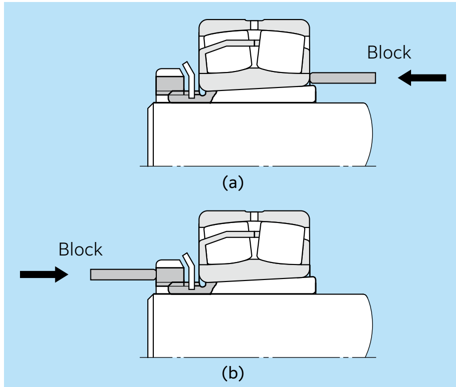

Fig. 15.35 Removal of bearing with adapter

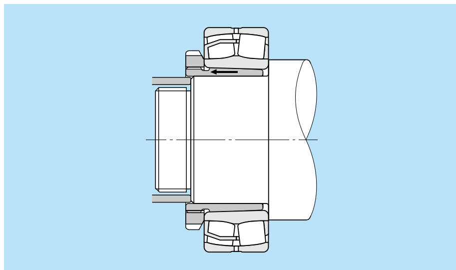

Fig. 15.36 Disassembly of bearing with withdrawal sleeve

For large type bearings on tapered shafts, adapters, or withdrawal sleeves, disassembly is greatly facilitated by hydraulic methods. **Fig. 15.37** shows the case where the bearing is removed by applying hydraulic pressure on the fitting surface of a bearing installed on a tapered shaft.

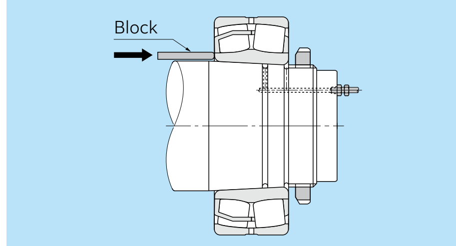

Fig. 15.37 Bearing disassembly using oil pressure

Fig. 15.38 shows two methods of disassembling bearings with adapters or withdrawal sleeves using a hydraulic nut. **Fig. 15.39** shows a disassembly method using a hydraulic withdrawal sleeve where high pressure oil is injected between fitting surfaces and a lock nut is then employed to remove the sleeve.

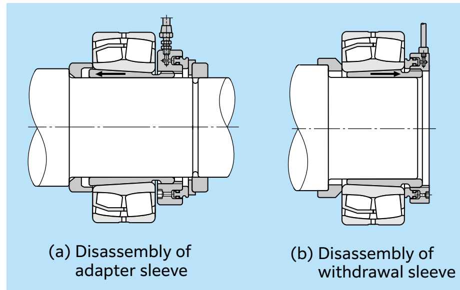

Fig. 15.38 Disassembly using hydraulic nut

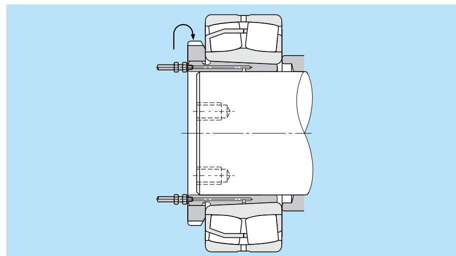

Fig. 15.39 Disassembly using hydraulic withdrawal sleeve

15.7 Bearing maintenance and inspection

Managing the condition of the machine during operation is important for preventing bearing failure. The following items are the general maintenance management methods.

(1) Inspection of machine while running
The interval for replenishing and replacing lubricant is determined by a study of lubricant properties and checking the bearing temperature, noise and vibration.

(2) Observation of bearing after use
Take note of any problem that may appear after the bearing is used or when performing routine inspections, and take measures for preventing reoccurrence of any damage discovered.

Maintenance management requires that the frequency for performing routine inspections be determined according to the importance of the device or machine.

15.7.1 Inspection of machine while running

15.7.1.1 Bearing temperature

In general, the bearing temperature increases after the start of operation and becomes steady at a slightly lower temperature after a certain time elapses (usually 10 to 40°C higher than the room temperature). The time until the temperature becomes steady differs depending on the bearing size, type, rotational speed, lubrication method, and heat dissipation condition of the bearing surroundings. It varies from 20 minutes to several hours.

When the bearing temperature does not become steady and rises excessively, the following may be the cause. Stop the operation and take measures.

<Main causes of abnormal temperature rise>

- Amount of lubricant too small or large
- Improper bearing installation
- Bearing internal clearance too small, or load too large
- Friction of sealing mechanism too large
- Unsuitable lubricant
- Creeping of fitting surface

The bearing temperature should not be too high to maintain suitable bearing operation and prevent the deterioration of lubricant. In general, it is best to use bearings at 100°C or below.

15.7.1.2 Bearing noise

To check bearing running noise, the sound can be checked and the type of noise can be ascertained with a listening instrument placed against the housing. A clear, smooth and continuous running sound is normal; however, determining the exact noise requires significant experience. Although it is difficult to express noise with words and it is different depending on the person, **Table 15.3** shows the characteristics and cause of the typical abnormal noises of bearings.

Table 15.3 Characteristics and cause of typical abnormal noise of bearings

Noise	Characteristics	Cause (probable)
Buzzing noise	—	• Entrance of foreign matter • Roughness of the surfaces of raceway, ball, roller • Scratches on the surfaces of raceway, ball, roller
Whoosh (small size bearings)	—	• Roughness of the surfaces of raceway, ball, roller
Short whoosh noise	• The noise is generated intermittently and regularly.	• Contact with labyrinth part • Contact of case and seal
Rubbing noise/ rumbling noise	• The noise magnitude and pitch change when the rotational speed is changed. The noise becomes loud at a certain rotational speed. The noise becomes loud and quiet. The noise sometimes resembles the sound of sirens and whistles (howling noise).	• Sympathetic vibration, fitting failure (shaft shape failure) • Deformation of raceway • Chattering noise of raceway, ball, roller (a little noise for large size bearings is normal)
Scraping noise/ crunchy noise	• Roughness felt when the bearing is rotated by hand	• Scratches on the raceway surface (regular) • Scratches on the ball or roller (irregular) • Dirt, deformation of raceway (partial negative clearance)
Grumbling noise	• Continuous noise in high speed rotation	• Scratches on the surfaces of raceway, ball, roller
Whirling noise	• The noise stops the moment the power is turned off.	• Electromagnetic sound of motor
Clinking noise (mainly with small size bearings)	• Irregular • The noise does not change when the rotational speed is changed.	• Entrance of foreign matter
Jingling noise (tapered roller bearings) Chattering noise (large size bearings) Flapping noise (small size bearings)	• The noise is regular and becomes continuous in high speed rotation. • Clear cage sound is normal.	• Unsuitable lubricant (use soft grease for low temperature) • Cage pocket abrasion, insufficient lubricant, insufficient bearing load operation
Ticking noise/ clacking noise/ clattering noise	• Conspicuous in low speed rotation • Continuous noise in high speed rotation	• Collision noise from cage pocket, insufficient lubrication. The noise stops by preloading or by making the internal clearance smaller. • Collision noise of rollers for the full component type
Clanging noise	• Loud metallic collision noise • Low-speed thin large size bearings	• Deformation of raceway
Sliding noise/ squeaky noise splashing sound	• Mainly with cylindrical roller bearings, the noise changes when the rotational speed is changed. Large noise sounds like metallic sound. The noise temporarily stops when grease is supplied.	• Lubricant (grease) consistency too high • Radial internal clearance too large • Insufficient lubricant
Squealing noise/ creaking noise/ whining noise	• Metal biting sound • High-pitched sound	• Biting between roller and flange surface of roller bearing • Internal clearance too small • Insufficient lubricant
Splashing noise	• Occurs irregularly with small size bearings	• Sound generated when bubbles in the grease are broken
Groaning noise/	• Irregular squeaky noise	• Slippage of fitting part • Squeakiness of mounting surface
Indistinguishable loud noise during operation.		• Roughness of the surfaces of raceway, ball, roller • Deformation of raceway surface, ball, and roller caused by abrasion • Too large internal clearance caused by abrasion

15.7.1.3 Bearing vibration

Measuring the machine vibration during operation with a vibration measuring instrument can reveal bearing damage at an early stage. The bearing damage degree can be estimated by quantitatively measuring and analyzing the vibration amplitude and frequency. However, measurement values differ depending on the measurement positions and bearing use conditions. Therefore, it is desirable to accumulate measurement data and set criteria for each machine.

When the bearing is damaged, vibration including specific frequencies that depend on the bearing internal specifications and rotational speed occurs. The bearing vibration frequency can be calculated with the bearing technique calculation tool on the **NTN** website (https://www.ntnglobal.com).

15.7.1.4 Leakage/abnormal deterioration of lubricant

The main causes of the leakage/abnormal deterioration of lubricant are as follows. It is necessary to take measures depending on the use conditions and environment.

- Too much lubricant
- Unsuitable lubricant
- Improper installation
- Unsuitable sealing mechanism
- Deterioration caused by use
- Unsuitable operating condition
- Abnormal deterioration

15.7.2 Observation of bearing after use

Carefully observe bearings after use and during periodic inspection, and take appropriate recurrence prevention measures if any damage was found. For details, see section “16. Bearing damage and corrective measures.”

15.8 Bearing maintenance tools

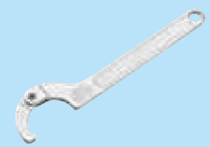
NTN offers maintenance tools for easily and safely installing/disassembling bearings. **NTN** also offers a portable abnormality detection device," a small vibration measurement device that has excellent portability and usability for measuring the vibration generated from the machine.

15.8.1 Maintenance tools

Figs. 15.40 through **15.49** show some of the main maintenance tools that are convenient for installing/disassembling bearings. For details, see the special catalog "**Maintenance tools (CAT. No. 6600/J)**."

The kit allows accurate, safe, and quick bearing installation.

Fig. 15.40 Cold mounting case



The five spanners allow tightening/loosening nuts of 30 different sizes.

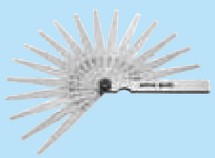
Fig. 15.41 Hook spanners

The device allows safe and secure heat fitting work and has an automatic demagnetization function, an overheat prevention function, and a temperature maintaining function.

Fig. 15.42 Induction heater

The protective gloves allow safe handling of high-temperature bearings up to 350°C.

Fig. 15.43 Heat-resistant gloves

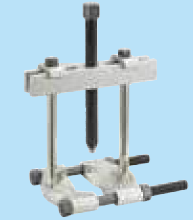


The tool allows simple and high precision measurement of bearing clearance.

Fig. 15.44 Set of calibrated feeler gauges

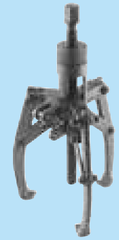
The jig allows quick and easy removal of bearings press-fitted into housings by a tight fit.

Fig. 15.45 Bore puller set



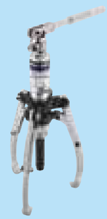
The jig allows safe and easy removal of bearings that are attached to shafts and difficult to remove.

Fig. 15.46 Back puller



The jig is a robust and simple tool for easily removing small and medium size bearings.

Fig. 15.47 Mechanical puller



The jig is efficient for easily and safely removing bearings press-fitted into shafts of large size bearings.

Fig. 15.48 Hydraulic puller

Removal can be done safely and efficiently by using the puller mechanically or hydraulically.

Fig. 15.49 Tri Section Pulling Plates

15.8.2 NTN PORTABLE VIBROSCOPE

NTN offers the "**NTN** PORTABLE VIBROSCOPE", a small vibration measurement device that has excellent portability and usability for performing FFT(Fast Fourier Transform) analysis and OA(Overall) measurement by wireless communication with tablets and smart devices with a dedicated application installed (**Fig. 15.50**).

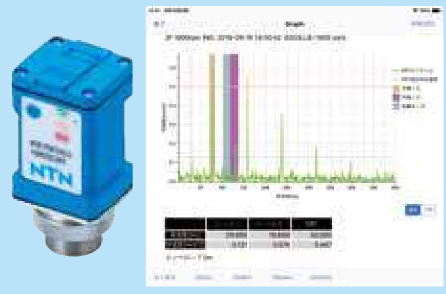


Fig. 15.50 NTN PORTABLE VIBROSCOPE

The FFT analysis clarifies the detailed operational state of the machine. By registering measurement conditions such as bearing part numbers and rotational speed, it is possible to detect the damage inside the bearing and estimate the damaged parts. In addition, selecting measurement conditions allows detecting abnormalities such as unbalance and misalignment of machines having rotating parts. In OA measurement, the acceleration, speed, and displacement can be displayed independently, and the measurement can be used as a general vibrometer.

The raw vibration data and the analysis results can be saved in smart devices for operation and can be downloaded in CSV format as necessary. In addition, the measurement device itself is dust-proof and drip-proof; therefore, the device is suitable for measuring vibration of machines used in various environments.

For the product details, please contact **NTN** Engineering.

For details, see the special catalog "**NTN PORTABLE VIBROSCOPE (CAT. No. 6601/E)**."

16. Bearing damage and corrective measures

16.1 Bearing damage, main causes of bearing damage, and remedies for correcting the problem

If handled correctly, bearings can generally be used for a long time before reaching their fatigue life. If damage occurs prematurely, the problem could stem from improper bearing selection, handling, or lubrication. If this occurs, take note of the application, operating conditions, and environment. By investigating several possible causes surmised from the type of damage and condition at the time the damage occurred, it is possible to prevent the same kind of damage from reoccurring. **Table 16.1** gives the main causes of bearing damage and remedies for correcting the problem.

For details, see the special catalog "**Care and maintenance of bearings (CAT. No. 3017/E)**."

Table 16.1 Bearing damage, main causes of bearing damage and remedies for correcting the problem

Phenomenon

Spalling (Flaking)
The surface of the raceway and rolling elements peel away in flakes leaving a highly irregular and very poor surface.

- Inner ring of spherical roller bearing
- Flaking on one row of the raceway surface in this case.
- An excessive axial load is the cause.

- Outer ring of angular contact ball bearing
- Flaking on the raceway surface with spacing equal to the distance between balls.
- Improper handling is the cause.

Causes
- Excessive load, normal fatigue life, improper handling
- Improper installation
- Insufficient accuracy of shaft or housing
- Insufficient clearance
- Contamination
- Rust
- Insufficient lubrication
- Reduction in hardness due to abnormal temperature rise

Correction
- Select a different type or size of bearing.
- Reevaluate the clearance.
- Improve the precision of the shaft and housing.
- Improve assembly method and handling.
- Reevaluate the layout (design) of the area around the bearing.
- Review lubricant type and lubrication methods.

Seizure
Extreme thermal conditions eventually resulting in seizure of the bearing.

- Inner ring of double-row tapered roller bearing
- Seizure causes discoloration and softening, producing stepped abrasion on the raceway surface with spacing equal to the distance between the rollers.
- Insufficient lubrication is the cause.

- Inner ring of tapered roller bearing
- Evidence of seizure on the large diameter side of raceway surface and large rib surface
- Insufficient lubrication is one possible cause.

Causes
- Insufficient clearance (including clearances reduced by local deformation)
- Insufficient lubrication or improper lubricant
- Excessive loads (including excessive preload)
- Roller skewing due to a misaligned bearing
- Reduction in hardness due to abnormal temperature rise
- High speed or large fluctuating load

Correction
- Review lubricant type and quantity.
- Check for proper clearance. (Increase clearances.)
- Take steps to prevent misalignment.
- Improve assembly method and handling.

Cracks/chips
Localized flaking occurs. Little cracks or notches appear.

- Inner ring of tapered roller bearing
- Chipped large rib.
- Impact due to improper preloading is the cause.

- Outer ring of four-row cylindrical roller bearing
- Cracks in the circumferential direction of raceway surface
- These cracks were initiated by flaking.

Causes
- Excessive shock loads
- Improper handling (use of steel hammer, damage from large particle contamination)
- Formation of decomposed surface layer due to improper lubrication
- Excessive interference
- Flaking
- Friction cracking
- Imprecise mating component (oversized fillet radius)

Correction
- Review lubricant (friction crack prevention).
- Select proper interference and review materials.
- Improve assembly method and handling.

Bearing Damage and Corrective Measures

Table 16.1 (continued)

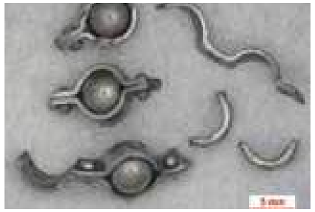
Phenomenon

Cage damage

Rivets break or become loose resulting in cage damage.
Fracture of riveted steel cage at the corner radius.

- Cage of angular contact ball bearing
- Breakage of high strength, machined brass cage
- Insufficient lubrication is the cause.

- Cage of cylindrical roller bearing
- Breakage of partitions between pockets of high strength, machined brass cage



- Cage of deep groove ball bearing
- Breakage of riveted steel cage

- Cage of deep groove ball bearing
- Breakage at corner of riveted steel cage

Causes

- Excessive load or moment loading
- High speed or excessive speed fluctuations
- Insufficient lubrication
- Impact with foreign objects
- Excessive vibration
- Improper mounting (mounted misaligned)

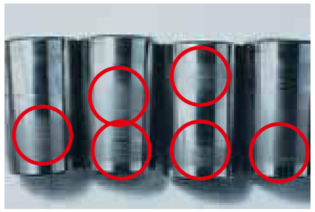
Correction

- Review lubricant type and lubrication methods.
- Review cage type selection.
- Investigate shaft and housing rigidity.
- Improve assembly method and handling.

Rolling path skewing

Abrasion or an irregular, rolling path skewing due to rolling elements along raceway surfaces.

- Spherical roller bearing
- Uneven contact on inner ring, outer ring, and roller
- Improper installation is the cause.



- Roller of tapered roller bearing
- Evidence of uneven contact on rolling element surface

Causes

- Insufficient accuracy of shaft or housing
- Improper installation
- Insufficient shaft or housing rigidity
- Shaft whirling caused by excessive internal bearing clearances

Correction

- Reevaluate the clearance.
- Improve the precision of the shaft and housing.
- Review rigidity of shaft and housing.

Smearing, Scuffing

The surface becomes rough and some small deposits form.
Scuffing generally refers to roughness on the race rib face and the ends of the rollers.

- Inner ring of cylindrical roller bearing
- Scuffing on the rib surface.

- Inner ring of cylindrical roller bearing
- Smearing on the raceway surface.
- The cause is slippage of rollers due to contaminants.

Causes

- Insufficient lubrication
- Contamination ingress
- Roller skewing due to a misaligned bearing
- Bare spots in the collar oil film due to large axial loading
- Excessive slippage of the rolling elements

Correction

- Review lubricant type and lubrication methods.
- Improve sealing performance.
- Review preload.
- Improve assembly method and handling.

Bearing Damage and Corrective Measures

Table 16.1 (continued)

Phenomenon

Rust/ corrosion

The surface becomes either partially or fully rusted, and occasionally rust occurs spaced at equal distances between rolling elements.

- Inner ring of tapered roller bearing
- Rust at equal distances between rolling elements on raceway surface.

- Outer ring of deep groove ball bearing
- Rust on the outer diameter surface.

Causes

- Poor storage conditions
- Poor packaging
- Insufficient rust inhibitor
- Penetration by water, acid, etc.
- Handling with bare hands

Correction

- Take measures to prevent rusting while in storage.
- Periodically inspect the lubricating oil.
- Improve sealing performance.
- Improve assembly method and handling.

Fretting

There are two types of fretting. In one, a rusty wear powder forms on the mating surfaces. In the other, brinelling indentations form on the raceway corresponding to rolling element spacing.

- Inner ring of cylindrical roller bearing
- Ripple-like fretting on the entire circumference of the raceway surface.
- Vibration is the cause.

- Inner ring of deep groove ball bearing
- Fretting on the entire circumference of the raceway surface.
- Vibration is the cause.

Causes

- Insufficient interference
- Small bearing oscillation angle
- Insufficient lubrication
- Fluctuating loads
- Vibration during transport, or while stopped

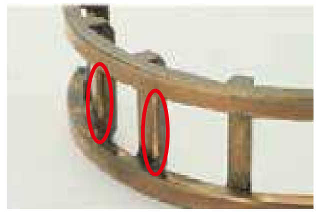
Correction

- Review lubricant type and lubrication methods.
- Review the interference fit and apply a coat of lubricant to fitting surface.
- Pack the inner and outer rings separately for transport.

Wear

The surfaces wear and dimensional deformation results.
Wear is often accompanied by roughness and scratches.

- Inner ring of cylindrical roller bearing
- Stepped wear on the entire circumference of the raceway surface.
- Insufficient lubrication is the cause.



- Cage of cylindrical roller bearing
- Wear of pocket part of high strength, machined brass cage

Causes

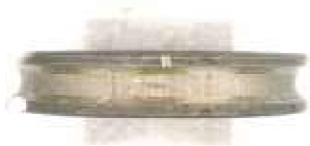
- Entrapment of foreign particles in the lubricant
- Inadequate lubrication
- Roller skewing due to a misaligned bearing

Correction

- Review lubricant type and lubrication methods.
- Improve sealing performance.
- Take steps to prevent misalignment.
- Improve assembly method and handling.

Electrolytic corrosion

Pits form on the raceway. The pits gradually grow into ripples.



- Inner ring of deep groove ball bearing
- Ripple-like electrolytic corrosion on the raceway surface.

- The cross section of the electrolytic corrosion on the roller rolling element surface is enlarged (×400).
- The white layer shows up by nital etching of the cross section.

Causes

- Electric current flowing through the rollers

Correction

- Create a bypass circuit for the current.
- Insulate the bearing.

Bearing Damage and Corrective Measures

Table 16.1 (continued)

Phenomenon

Dents and scratches

Scoring during assembly, gouges due to hard foreign objects, and surface denting due to mechanical shock.

- Roller of cylindrical roller bearing
- Axial direction scratches on the rolling element surface at the time of preloading
- Improper preloading is the cause.

- Inner ring of tapered roller bearing
- Dents on the entire raceway surface
- Impact with hard foreign objects is the cause.

Causes
- Entrapment of hard foreign matter
- Dropping or other mechanical shocks due to careless handling
- Assembled misaligned
- Excessive load or moment loading

Correction
- Improve assembly method and handling.
- Improve sealing performance. (to prevent infiltration of foreign matter)
- Check area surrounding bearing. (when caused by metal fragments)

Creeping

Surface becomes mirrored due to inner and outer diameter bearing surfaces spinning against the mating shaft or housing surface during operation. May be accompanied by discoloration or scoring.

- Inner ring of deep groove ball bearing
- Mirrored bore surface due to creeping on the shaft.

- Inner ring of tapered roller bearing
- Scuffing on bearing bore surface due to creeping on the shaft.

Causes
- Insufficient interference with mating component
- Sleeve not fastened down properly
- Abnormal temperature rise
- Excessive loads
- High speed/rapid acceleration or deceleration

Correction
- Reevaluate the interference fit.
- Review operating conditions.
- Improve the precision of the shaft and housing.
- Fix of the faces of inner/outer ring

Speckles and discoloration

Luster of raceway surfaces is gone; surface is matted, rough, and / or evenly dimpled. Surface covered with minute dents.

- Inner ring of double-row tapered roller bearing
- Speckles and discoloration on the raceway surface.
- Electrolytic corrosion is the cause.

- Ball of deep groove ball bearing
- Large speckles and discoloration
- Impact with hard foreign objects and insufficient lubrication are the cause.

Causes
- Infiltration of bearing by foreign matter
- Insufficient lubrication

Correction
- Review lubricant type and lubrication methods.
- Review sealing mechanisms.
- Examine lubrication oil purity. (filter may be excessively dirty, etc.)

Peeling

Patches of minute flaking or peeling (size, approx. 10 μm). Innumerable hair-line cracks visible though not yet peeling. (This type of damage is frequently seen on roller bearings.)

- Spherical rollers
- Linear peeling on the rolling element surface.
- Insufficient lubrication is the cause.

- Outer ring of deep groove ball bearing
- Peeling on the load zone of the raceway surface.

Causes
- Infiltration of bearing by foreign matter
- Insufficient lubrication

Correction
- Review lubricant type and lubrication methods.
- Improve sealing performance. (to prevent infiltration of foreign matter)
- Perform run-in.

Bearing Damage and Corrective Measures

Table 16.2 gives the main causes of bearing damage. In the table, factors that are likely to be the cause of each damage are marked by ○; however, factors without ○ may be the cause of the damage in special circumstances.

Table 16.2 Bearing damage and causes

Bearing damage	Damaged parts	Handling: Poor storage condition/ vibration during transportation	Handling: Improper handling/ installation	Bearing periphery: Insufficient accuracy of shaft/housing	Bearing periphery: Infiltration of bearing by foreign matter (insufficient sealing performance)	Bearing periphery: Temperature (heat effect)	Lubrication: Lubricant (insufficient/ improper quality)	Lubrication: Lubrication method (insufficient)	Load: Excessively large impact load/preload	Load: Excessively large moment	Load: Excessively small load	Speed: High speed/ rapid acceleration and deceleration	Speed: Large vibration	Speed: Swinging/vibration/ standstill	Bearing selection: Excessively large/ small clearance	Bearing selection: Excessively large/ small interference
Flaking (separation)	Raceway surface/ rolling element surface		○	○	○	○	○	○	○	○					○	
Seizure	Raceway/ rolling element/cage		○			○	○	○	○	○		○			○

Peeling	Raceway surface/ rolling element surface				○		○	○								

16.2 Rolling paths and how load is applied

When a bearing rotates in response to a load, the raceway surfaces of the inner and outer rings develop a hazy rolling path due to rolling contact with the rolling element. The rolling path on the raceway surface is normal. Evaluation of the rolling path of a used bearing can provide the engineer with useful information regarding the conditions the bearing had been exposed to.

Rolling path observation clarifies if a radial load was applied, an axial load was applied, or a moment load was applied. It can also shows if the bearing experienced a large load or a mounting error. These observations provide extremely important references when determining the cause of bearing damage.

Figure 16.1 shows rolling paths of point and linear contacts caused under various load conditions.

(1) is a general rolling path generated when a radial load is applied to a bearing with inner ring rotation. The width of the rolling path becomes small at the entrance of the load zone of the outer ring, which is the fixed side. On the other hand, (2) shows a rolling path pattern opposite to (1) when a radial load is applied during outer ring rotation. (3) is a rolling path generated when an axial load in one direction is applied to a bearing, and an example of linear contact on a spherical roller bearing. When a combined load is applied during inner ring rotation, a rolling path pattern such as (4) is caused. As shown in (5), when a radial load is applied to a bearing with significant misalignment due to a moment load, rolling paths are generated at two positions separated by 180 degrees in the load zone of the outer ring, which is the fixed side. (6) shows the case where the housing bore diameter is an ellipse. Rolling paths are left on the fixed side outer ring at two positions but are not misaligned. (5) and (6) indicate improper bearing use, and the bearing life may be shorter because of the adverse effect.

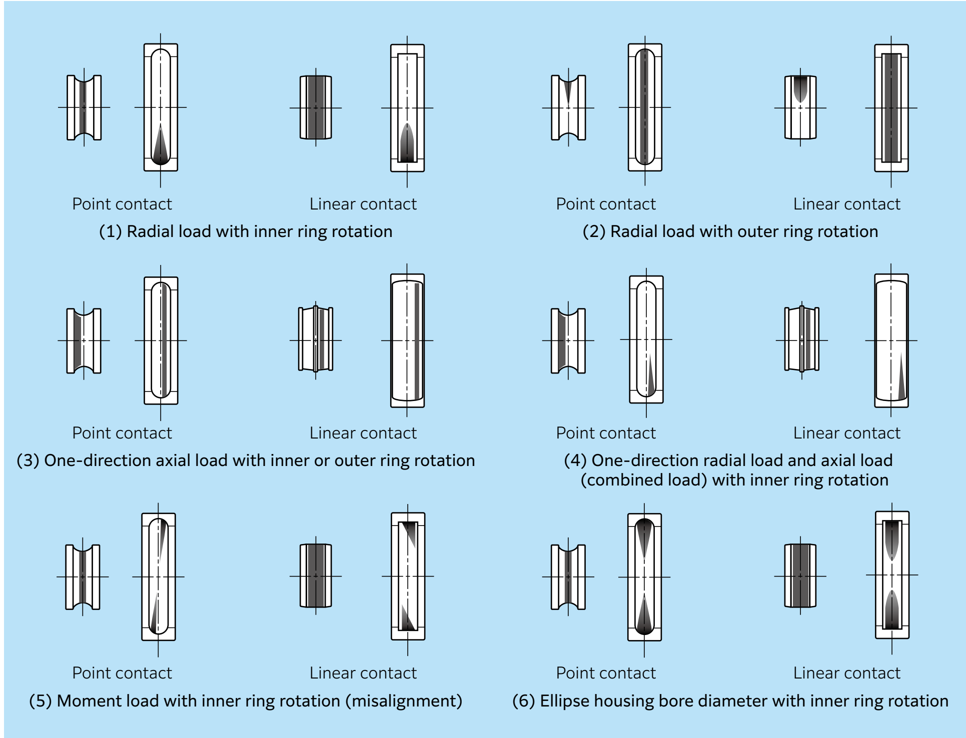

Figure 16.1 Rolling paths and how load is applied

*This technical data shows calculated values based on representative values, **NTN** does not guarantee these values.

17.3 Allowable axial load

17.3.1 Deep groove ball bearings

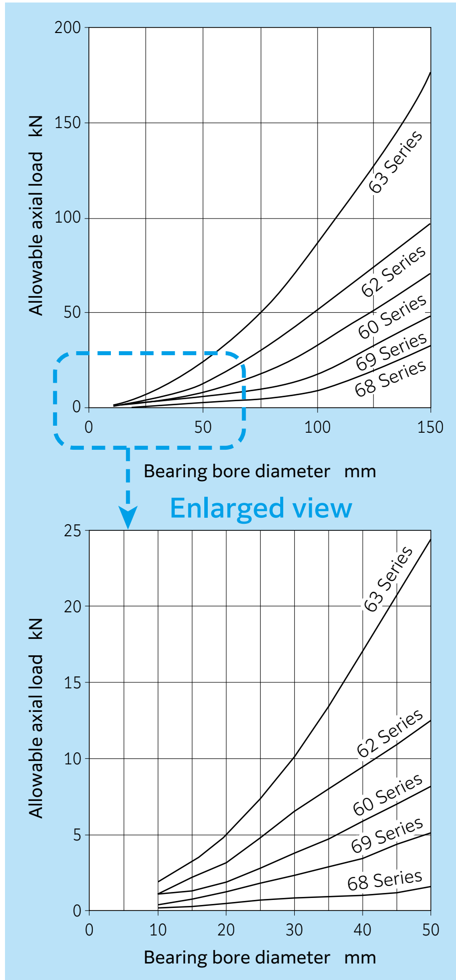

Fig. 17.3.1 Allowable axial load for deep groove ball bearings

Note: 1. Calculation of the allowable axial load uses the median of the radial clearance CN.
2. When an axial load is applied, the allowable axial load is the load whereby the contact ellipse exceeds the shoulder of the raceway.
3. Please consult **NTN** Engineering for other types and sizes.

17.3.2 Angular contact ball bearings

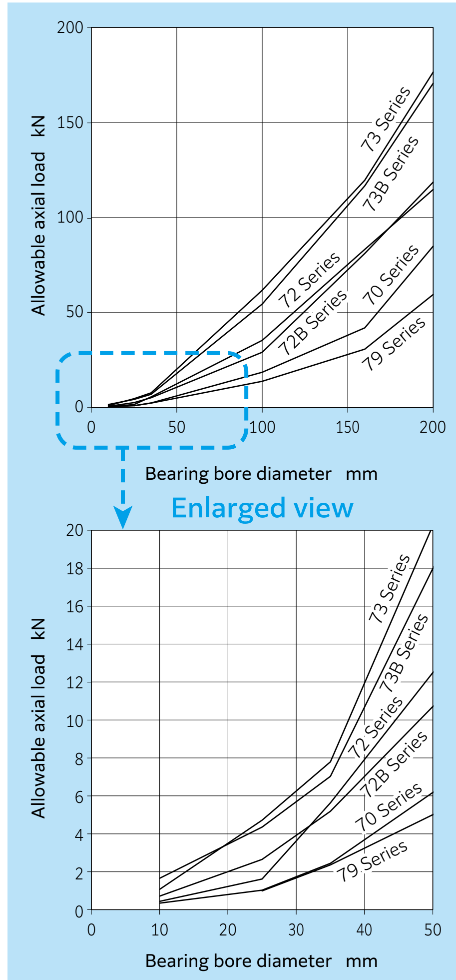

Fig. 17.3.2 Allowable axial load for angular contact ball bearings

Note: 1. When an axial load is applied, the allowable axial load is the load whereby the contact ellipse exceeds the shoulder of the raceway.
2. Please consult **NTN** Engineering for other types and sizes.

17.4 Fitting surface pressure

Table 17.4.1 lists equations for calculating the pressure and maximum stress between fitting surfaces.

Table 17.4.2 can be used to determine the approximate average groove diameter for bearing inner and outer rings.

The effective interference, in other words the actual interference Δ_{deff} after fitting, is smaller than the apparent interference Δd derived from the measured values for the bearing bore diameter and shaft. This difference is due to the roughness or variations of the finished surfaces to be fitted. Due to this, it is necessary to assume the following reductions in effective interference:

For ground shafts: 1.0 to 2.5 μm

For lathed shafts: 5.0 to 7.0 μm

Figure 17.4.1 and **Figure 17.4.2** show the root approximate values of the fitting surface pressure and the maximum stress when the solid steel shaft and the inner ring of 0 class bearings (d/D_i = 0.8) are fit.

Table 17.4.1 Fitting surface pressure and maximum stress

Fit condition		Calculation formula	Symbol (Unit: N, mm)
Fitting surface pressure MPa	Two cylinders General type	$P=\dfrac{E_1 E_2}{E_2\left\{\dfrac{(d_1^2+d_2^2)}{(d_1^2-d_2^2)}+\nu_1\right\}+E_1\left\{\dfrac{(d_2^2+d_3^2)}{(d_2^2-d_3^2)}-\nu_2\right\}}\cdot\dfrac{\Delta d_e}{d_2}$	P : Fitting surface pressure E_1, E_2 : Young's modulus of outer and inner cylinders ν_1, ν_2 : Poisson's ratio of outer and inner cylinders Δd_e : Effective interference of two cylinders 	Solid steel shaft/ inner ring fit	$P=\dfrac{E}{2}\,\dfrac{\Delta_{deff}}{d}\left[1-\left(\dfrac{d}{D_i}\right)^2\right]$	d : Shaft diameter, inner ring bore diameter d_o : Hollow shaft inner diameter D_i : Inner ring average groove diameter Δ_{deff} : Effective interference E : Longitudinal elasticity factor = 208,000 MPa 	Hollow steel shaft/ inner ring fit	$P=\dfrac{E}{2}\,\dfrac{\Delta_{deff}}{d}\,\dfrac{[1-(d/D_i)^2]\,[1-(d_o/d)^2]}{[1-(d_o/D_i)^2]}$	
	Steel housing/ outer ring fit	$P=\dfrac{E}{2}\,\dfrac{\Delta_{Deff}}{D}\,\dfrac{[1-(D_o/D)^2]\,[1-(D/D_h)^2]}{[1-(D_o/D_h)^2]}$	D : Housing inner diameter, bearing outer diameter D_o : Outer ring average groove diameter D_h : Housing outer diameter Δ_{Deff} : Effective interference Maximum stress MPa	Shaft/ inner ring fit	$\sigma_{t\,max}=P\,\dfrac{1+(d/D_i)^2}{1-(d/D_i)^2}$	Inner ring bore diameter maximum circumferential stress.
	Housing/ outer ring fit	$\sigma_{t\,max}=P\,\dfrac{2}{1-(D_o/D)^2}$	Outer ring outer diameter maximum circumferential stress.

Table 17.4.2 Average groove diameter (approximate expression)

Bearing type		Average groove diameter: Inner ring	Average groove diameter: Outer ring
Deep groove ball bearings	All types	$1.05\,\dfrac{4d+D}{5}$	$0.95\,\dfrac{d+4D}{5}$
Self-aligning ball bearings	12	$1.03\,\dfrac{3d+D}{4}$	$0.97\,\dfrac{d+2D}{3}$
	13, 22	$1.03\,\dfrac{3d+D}{4}$	$0.97\,\dfrac{d+3D}{4}$
	23	$1.03\,\dfrac{4d+D}{5}$	$0.97\,\dfrac{d+4D}{5}$
Cylindrical roller bearing 1)	All types	$1.05\,\dfrac{3d+D}{5}$	$0.98\,\dfrac{d+3D}{4}$
Spherical roller bearings	Type B, type C, type 213	$\dfrac{2d+D}{3}$	$0.97\,\dfrac{d+4D}{5}$
	ULTAGE	$\dfrac{3d+D}{4}$	$0.98\,\dfrac{d+5D}{6}$
Tapered roller bearings	All types	$\dfrac{3d+D}{4}$	$\dfrac{d+3D}{4}$

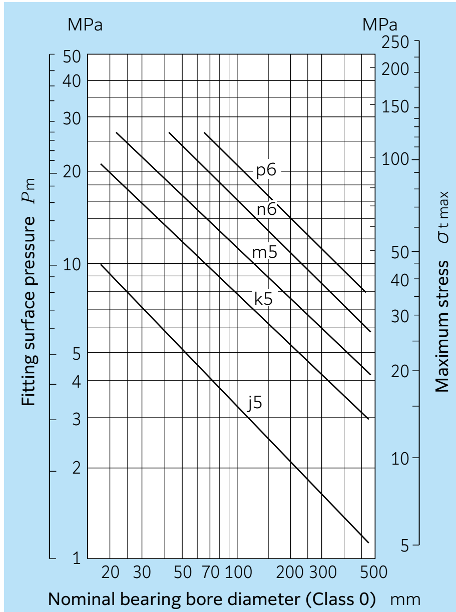

Fig. 17.4.1 Average fit interference as it relates to surface pressure P_m and maximum stress $\sigma_{t\,max}$

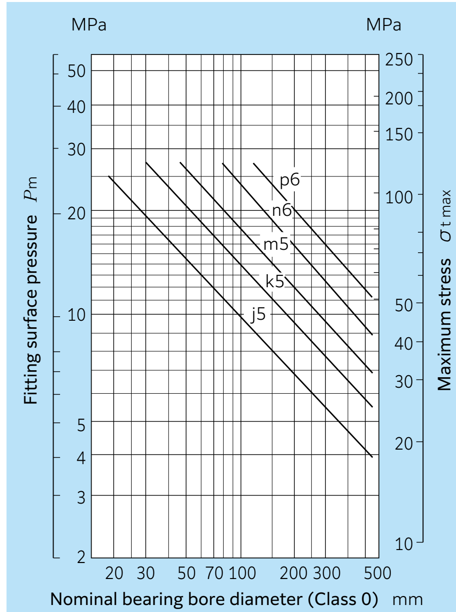

Fig. 17.4.2 Maximum fit interference as it relates to surface pressure P_m and maximum stress $\sigma_{t\,max}$

Note: For the recommended fitting, see the section of "7.3.2 Recommended fitting."

17.5 Necessary press fit and pullout force

Equations (17.1) and (17.2) below can be used to calculate the necessary pullout force for press fits on inner rings and shafts or outer rings and housings. The force obtained by the equations only serves as an approximation, and a larger load may be required for the actual installation and removal.

For shaft and inner rings:

$$K_{\mathrm{d}} = \mu \cdot P \cdot \pi \cdot d \cdot B \quad \cdots\cdots\cdots\cdots\cdots (17.1)$$

For housing and outer rings:

$$K_{\mathrm{D}} = \mu \cdot P \cdot \pi \cdot D \cdot B \quad \cdots\cdots\cdots\cdots\cdots (17.2)$$

Where:

K_{d} : Inner ring press fit or pullout force N
K_{D} : Outer ring press fit or pullout force N
P : Fitting surface pressure MPa (see **Table 17.4.1**)
d : Shaft diameter, inner ring bore diameter mm
D : Housing inner diameter, outer ring outer diameter mm
B : Inner or outer ring width mm
μ : Sliding friction coefficient (see **Table 17.5.1**)

Table 17.5.1 Press fit and pullout sliding friction coefficient

Concern	μ
Inner (outer) ring press fit onto cylindrical shaft (bore)	0.12
Inner (outer) ring pullout from cylindrical shaft (bore)	0.18
Inner ring press fit onto tapered shaft or sleeve	0.17
Inner ring pullout from tapered shaft	0.14
Sleeve press fit onto shaft/bearing	0.30
Sleeve pullout from shaft/bearing	0.33

17.6 Bearing technique calculation tool

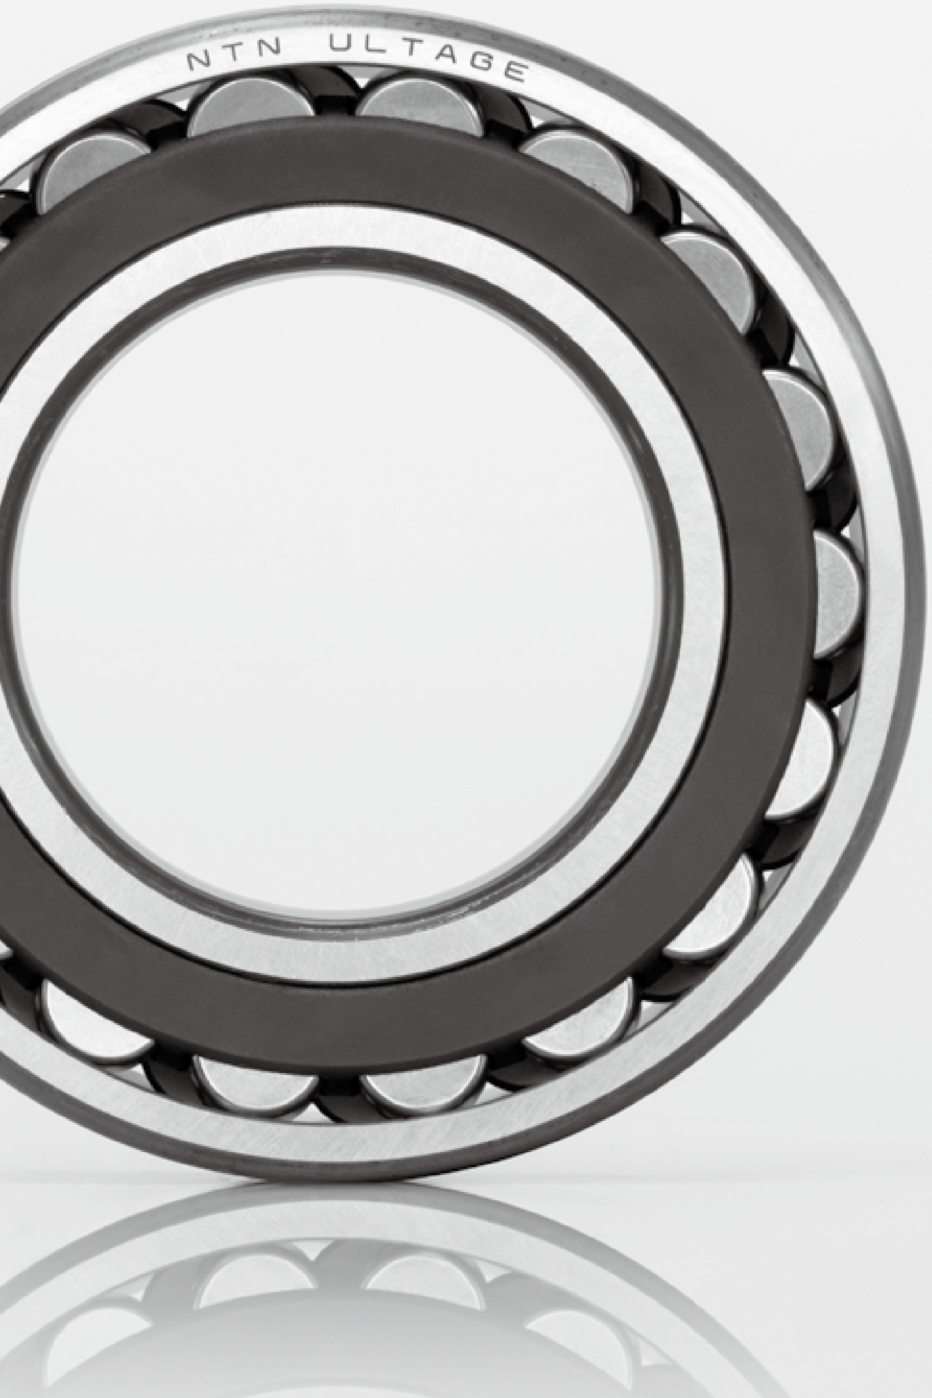
The following calculations can be performed by using the bearing technique calculation tool on the **NTN** website (https://www.ntnglobal.com).

- Basic rating life calculation of single bearing
- Basic rating life calculation of gear load and bearing
- Basic rating life calculation of bearing load and bearing
- Calculation of operating clearance
- Calculation of bearing vibration frequency

Ball and Roller Bearings

INDEX OF BEARING TABLES

NTN New Generation Bearings (ULTAGE Series)



Introduction of ULTAGE series

"ULTAGE" (a name created from the combination of "ultimate," signifying refinement, and "stage," signifying **NTN**'s intention that this series of products be employed in diverse applications) is the general name for **NTN**'s new generation of rolling bearings that are noted for their industry-leading performance. **NTN** is developing and expanding the ULTAGE series of each bearing type. Please see the introductory article on the following pages. The corresponding dimensions are specified in the dimension tables of each bearing type.

For details, see the following **NTN** catalogs.

ULTAGE series	cylindrical roller bearings	CAT.No.3037/E
ULTAGE metric series	large size tapered roller bearings	CAT.No.3035/E
ULTAGE series	spherical roller bearings [Type EA, Type EM]	CAT.No.3033/E

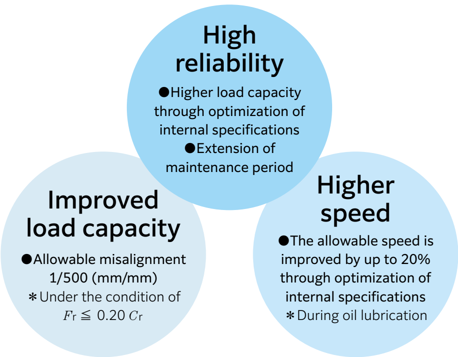
The following ULTAGE series bearings for special applications are also available.

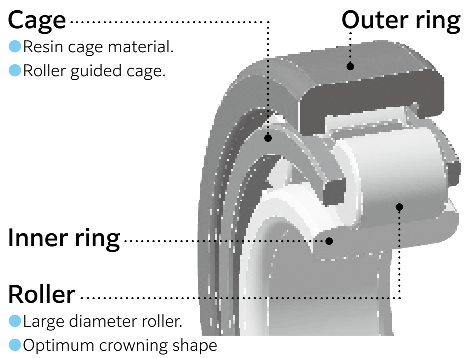
For further details, please refer to the section of "C. Special application bearings."

ULTAGE series	sealed four-row tapered roller bearings for rolling mill roll necks [CROU···LL type]
ULTAGE series	sealed spherical roller bearings [WA type]
ULTAGE series	spherical roller bearings with high-strength cage [EMA type]
ULTAGE series	deep groove ball bearings for high-speed servo motors [MA type]
ULTAGE series	precision rolling bearings for machine tools

Cylindrical roller bearings [ULTAGE series]

ULTAGE series cylindrical roller bearings are the standard series developed to meet the demands of "long operating life," "improved load capability," and "higher speed" that are required for various industrial machinery.





Features

1.Industry leading load rating

Higher load capacity and longer operating life have been realized through the optimization of internal specifications.

(1) Rating life: Up to 1.8 times longer (compared with NTN E type product)

(2) Basic dynamic load rating: Up to 20% higher (compared with NTN E type product)

2. Allowable misalignment (refer to Fig. 1)

Allowable misalignment: 1/500 (mm/mm)

Optimization of the roller crowning allows a combination of heavy loads (0.20 C_r) and allowable misalignment of 1/500 (mm/mm).

∗Necessary minimum load: 0.04 C_{0r}

3. Allowable speed

The allowable speed is increased up to 20% in oil lubrication (compared with NTN E type product).

4. Standard resin cage (refer to Fig. 2)

(1) Higher speed and longer operating life have been realized through the use of a window type combined PA resin cage.

(2) Resin cage materials: reinforced PA + GF

∗When machined cages are necessary for high speed and other special applications, consult **NTN** Engineering.

5. Interchangeability

The boundary dimensions conform to ISO 15, JIS B 1533, and DIN 5412 and are the same as that of the NTN E type products.

6. Allowable axial load

Same as NTN E type product

7. Allowable temperature

Allowable bearing operating temperature:
120°C (instantaneous) 100°C (continuous)

Bearing number

Cylindrical roller bearing

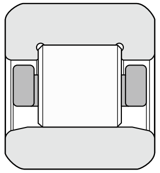
NU 22 04 EA T2X C3

- C3 — Radial internal clearance: C3
- T2X — Cage code: resin cage
- EA — **Type code: ULTAGE**
- 04 — Nominal bearing diameter: 20 mm
- 22 — Dimension series: 22
- NU — Bearing type: cylindrical roller bearing NU type

∗When the bearing is the NUP type, a code U is added at the end of the part number.

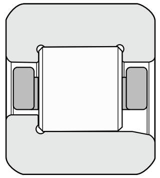
NTN

[Bearing type]



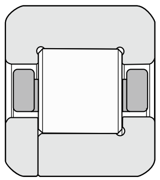
NU type structure
- Outer ring (with double flange)
- Roller
- Cage
- Inner ring (with no flanges)

The outer ring, roller, cage assembly, and inner ring can be separated.



NJ type structure
- Outer ring (with double flange)
- Roller
- Cage
- Inner ring (with single flange)

The outer ring, roller, cage assembly, and inner ring can be separated.

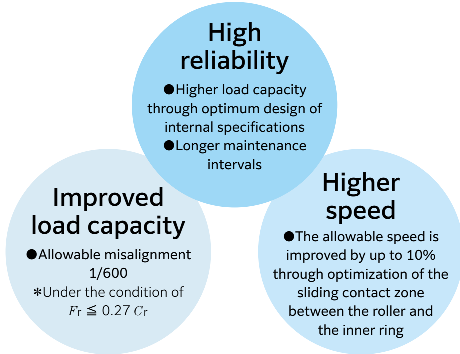


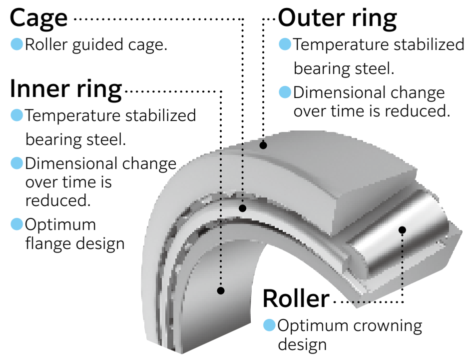
NUP type structure
- Outer ring (with double flange)
- Roller
- Cage
- Inner ring (with single flange)
- Inner ring collar ring

The outer ring, roller, cage assembly, inner ring, and collar ring can be separated.

Large size tapered roller bearings [ULTAGE metric series]

Large size tapered roller bearings (ULTAGE metric series with an outer diameter of ϕ270 mm or more) are the standard series developed to meet the demands of "long operating life," "improved load capability," and "higher speed" that are required for various industrial machinery.





Features

1. Industry leading reliability

The bearing load carrying capability has been improved by optimizing the roller crowning to reduce edge stress and allow a more uniform pressure distribution across the contact surface (see **Fig. 1**).

(1) Rating life: 3 times longer (compared to conventional NTN products)

(2) Basic dynamic rating load: 30% larger (compared to conventional NTN products)

2. Allowable misalignment

Allowable misalignment (single row): 1/600

Optimization of the roller crowning has allowed a combination of heavy loads (0.27 C_r) and allowable misalignment of 1/600.

*Necessary minimum load: 0.04 C_{0r}

Fig. 1 shows the contact surface pressure distribution of rollers considering an applied radial load of $F_r \leqq 0.27\ C_r$. By optimizing the roller crowning, the edge stress is greatly reduced and the contact surface pressure is made uniform compared with conventional products.

[Examined condition]

Bearing model : ULTAGE product and conventional NTN product (ϕ80 × ϕ170 × 42.5)
Load : 0.27 C_r
Allowable misalignment : 1/600

*The allowable misalignment differs depending on the loads and the bearing type. Please consult **NTN** Engineering.

3. Allowable speed

The allowable speed is improved by up to 10% (compared with the conventional NTN products) by optimizing the sliding contact zone between the roller and the inner ring, thus reducing the rotational torque and temperature rise (see **Fig. 2**, **Fig. 3**, and **Fig. 4**).

4. Dimensional change over time

Dimensional change of bearings over time has been reduced compared with conventional products by applying special heat treatment to bearing steel.

- Reduction in dimension change over time
  Conventional heat treatment : 1/10
  Case hardened steel ratio : 1/4

5. Interchangeability

The boundary dimensions conform to JIS B 1512-3 and ISO 355, and the installation dimensions are the same as that of the conventional NTN products.

In addition, the precision also conforms to JIS B 1514-1 and ISO 492.

- **UTG** — **Type code: ULTAGE**
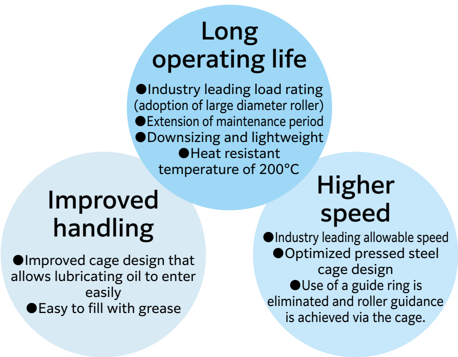
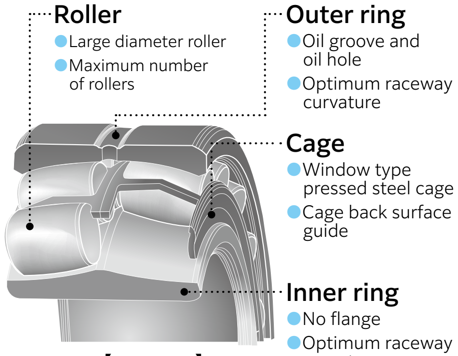
- **32** — Nominal bore diameter: 160 mm
- **31** — Dimension series: 31
- **32** — Bearing type: double row face-to-face tapered roller bearing

Spherical roller bearings [ULTAGE series EA/EM types]

ULTAGE series spherical roller bearings are the standard series developed to meet the demands of "long operating life," "higher speed," and "improved easy handling" that are required for various industrial machinery.





【EA type】

Features【EA type】

1. Industry leading load rating

Higher load capacity and longer operating life are realized by increasing the roller diameter and maximizing the number of rollers. This allows extension of the maintenance period (see **Fig. 1**).

(1) Basic dynamic rating load: Up to 65% higher (compared to conventional products)

(2) Basic static rating load: Up to 35% higher (compared to conventional products)

(3) Rating life: Up to 5 times longer (compared to conventional products)

2. Allowable speed of the world's highest level

Higher speed is realized through the adoption of a new pressed steel cage design.
[Allowable speed: 20% higher (compared to conventional products)]

3. Standard use of pressed steel cage

For the pressed steel cage, "window type" with rigidity is adopted, and the roller pocket is provided with four tabs (projections) (see **Fig. 2** and **Fig. 3**).

(1) Cage back surface used for guidance.

(2) The four pocket tabs stabilize the position of rollers.

(3) The new pocket shape allows consistent supply of lubricating oil and grease to the internal bearing surfaces (see **Fig. 4**).

(4) Special surface treatment is applied to the entire surface to improve the abrasion resistance.

4. Downsizing and lightweight

High-load capacity has allowed for downsizing and a lighter weight.

Comparison example

Bearing number	Rating load (kN)		Boundary dimension (mm)	Bearing volume (cm^3)	Mass (kg)
	C_r	C_{0r}			
22220B	315	415	ϕ100×ϕ180×46	810	4.95
22218EA	**385**	**398**	**ϕ90×ϕ160×40**	**550**	**3.28**

The volume weight and mass weight can be reduced by about 30%.

5. Improved handling

Adoption of the simple window type new pressed steel cage improved the workability at the time of assembly, disassembly, and grease application.

(1) Easy to fill with grease to roller surface

(2) Easy assembly and disassembly due to small roller drop

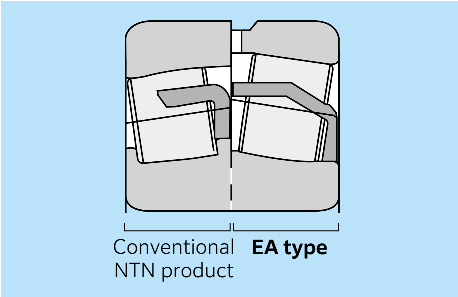


Fig. 1

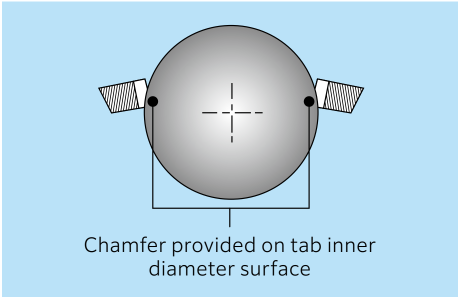

Fig. 3

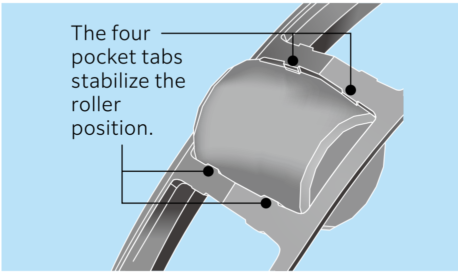

Fig. 2

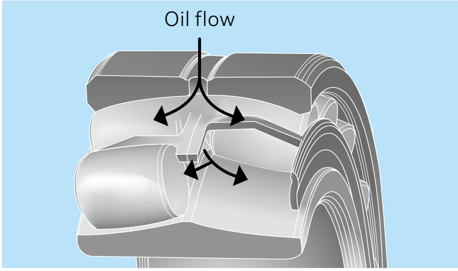

Fig. 4

Bearing number

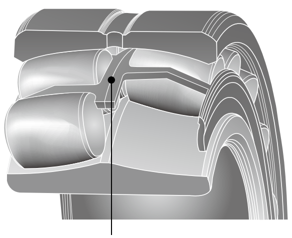
Spherical roller bearing

222 20 EA K D1 C3

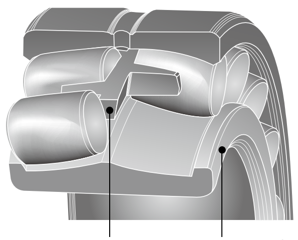
- **C3** — Internal clearance code
  - No code: normal clearance
  - C3: C3 clearance
- **D1** — Oil groove and oil hole code
  - D1 : oil groove and oil hole (Japan specification)
  - W33: oil groove and oil hole (Europe specification)
- **K** — External configuration code
  - No code: inner diameter cylindrical bore
  - K : tapered bore
- **EA** — **Type code**
  - EA : window type pressed steel cage
  - EM: one-piece high strength, machined brass cage
- **20** — Bore diameter code
- **222** — Dimension series code

A combined machined cage (EM type) is recommended for conditions with severe vibration and impact. (EM type and EA type have different inner ring shapes.)

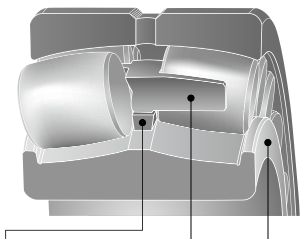
EA type



EM type



EM type (large size)



[Allowable misalignment]

- ●Normal load or more …… 1/115
- ●Light load …………………… 1/30

*Misalignment beyond the above limits may cause the roller to protrude from the outer ring, causing interference with the peripheral components.

Deep Groove Ball Bearings

Open type

Shielded type

Sealed type (non-contact)

Expansion compensating bearing

1. Design features and characteristics

Deep groove ball bearings are very widely used. A deep groove is formed on the inner and outer ring of the bearing enabling the bearing to sustain radial and axial loads in either direction as well as the complex loads which result from the combination of these forces. Deep groove ball bearings are suitable for high speed applications.

When two or more deep groove ball bearings are used in combination and mounted adjacent to each other a duplex set (D2) should be used. Duplex bearings (D2) utilize controlled tolerances to more evenly distribute the loading between the individual bearing rows which improves the overall performance of the assembly.

In addition to unsealed and unlubricated "open" bearings, **NTN** provides deep groove ball bearings that are pre-lubricated with grease and enclosed by seals or shields. See section "11. Lubrication" for a list of some of the greases which can be used.

Table 1 shows the construction and special characteristics of various sealed deep groove ball bearings.

Table 1 Sealed ball bearings: construction and characteristics

Types and codes		Shielded type	Sealed type		
		Non-contact type ZZ	Non-contact type LLB	Contact type LLU	Low torque type LLH
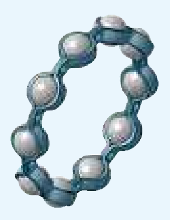
Construction							● Metal shield plate is affixed to the outside ring; the inner ring incorporates a V-groove and labyrinth clearance.	● The outer ring incorporates synthetic rubber molded to a steel plate; seal edge is aligned with V-groove along inner ring surface with labyrinth clearance.	● The outer ring incorporates synthetic rubber molded to a steel plate; seal edge contacts V-groove along inner ring surface.	● Basic construction is the same as LLU type, but a specially designed lip on the edge of the seal prevents foreign matter penetration; low torque construction.
Performance comparison	Torque	Small	Small	Higher	Medium
	Dust proofing	Good	Better than ZZ-type	Excellent	Much better than LLB-type
	Water proofing	Poor	Poor	Very good	Good
	High speed capacity	Same as open type	Same as open type	Limited by contact seals	Much better than LLU-type
	Allowable temp. range[1)]	Depends on lubricant	−25 to 120°C	−25 to 110°C	−25 to 120°C

1) Please consult **NTN** Engineering about applications which exceed the allowable temperature range of products listed on this table.
Note: This chart lists double shielded and double sealed bearings, but single shielded (Z) and single sealed (LB, LU, LH) are also available. Grease lubrication should be used with single shielded and single sealed bearings.

2. Standard cage type

As shown in **Table 2**, pressed steel cages are generally used for most deep groove ball bearings. Larger size deep groove ball bearings, and bearings operating at high rotational speeds often utilize a machined metallic cage.

Table 2 Standard cage for deep groove ball bearings

Cage type / Bearing series	Pressed cages	Machined cages
		


67	6700～ 6706	—
68	6800～ 6834	6836～ 68／600
69	6900～ 6934	6936～ 69／500
160	16001～16052	16056～16072
60	6000～ 6052	6056～ 6084
62	6200～ 6244	—
63	6300～ 6344	—
64	6403～ 6416	—

3. Other deep groove ball bearing enhancements

3.1 Bearings with snap rings

A snap ring grove or snap ring groove with snap ring combination are optional enhancements for the outer diameter of most deep groove ball bearings. Snap rings allow for simpler axial positioning and installation in the housing. Snap rings can be utilized with both open type and sealed or shielded deep groove ball bearings. Consult **NTN** Engineering.

3.2 Expansion compensating bearings (creep prevention bearings)

NTN offers the innovative Expansion Compensating (EC) feature to help with bearing retention when mounted in light alloy housings which is often a problem at elevated temperatures due to property differences between the bearing steel and the housing. This functionality is achieved by machining circumferential grooves into the outer diameter of an otherwise standard outer ring. These grooves are filled with an optimized polymer which has an expansion rate higher than that of the typical light alloy housing. The net result is a more consistent interference fit across a wide operating temperature range. This more consistent fit condition helps prevent the bearing from rotating within the housing (known as bearing creep) which helps ensure good performance and long life.

(1) Allowable load

As a result of having grooves machined in the outer diameter, the ring strength is lower compared with a standard bearing. Thus, **in order to prevent outer ring fracture, it is necessary to limit the maximum load applied to the bearing to be equal to or less than the allowable load C_p (see dimension table)**.

(2) Fit with housing

Table 3 shows the recommended fits for bearings with light metal alloy housings. In cases where the bearing is going to be interference fit with the housing, it is very important not to damage the polymer material. Therefore, it is essential that the lip of the housing diameter be given a 10-15° chamfer as shown in **Fig. 2**. Furthermore, as shown in **Fig. 2**, it is also advisable to apply the interference fit using a press in order not to force the bearing into the housing in a misaligned position.

Deep Groove Ball Bearings NTN

Table 3 Recommended fits for outer ring and housing bore

Condition: Load type, etc.		Condition: Housing material	Suitable bearing	Housing bore tolerance class
Rotating outer ring load Rotating inner ring load	Light load	Light alloys such as Al alloy and Mg alloy	Deep groove ball bearings Cylindrical roller bearings	H6
Indeterminate load	Normal load			
Rotating outer ring load	Heavy load	Light alloys such as Al alloy and Mg alloy	Thick-walled type deep groove ball bearings	N6
Indeterminate load	Impact load			

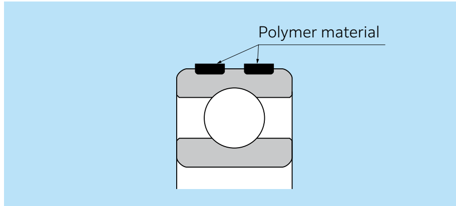


Fig. 1. Expansion compensating bearings

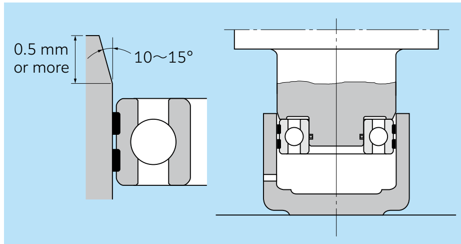

Fig. 2. Fitting method and housing inner diameter chamfer

(3) Radial internal clearance

Radial internal clearance are the same as those for standard deep groove ball bearings. With standard fit and application conditions, a C3 clearance is used. For more detailed information concerning this bearing and the availability of roller bearings contact **NTN** Engineering.

(4) Allowable temperature range

−20 to 120°C

3.3 AC bearings (creep prevention bearings)

NTN Offers the AC type bearing which performs a similar function to the EC bearing. AC bearings have the same outer diameter dimensions as standard bearings with the addition of two O-rings located in circumferential grooves on the outside diameter of the outer ring. (**Fig. 3**) While the EC bearing is more beneficial when using a light alloy housing at elevated temperatures, AC bearings are suitable for applications where a “tight fit” is not possible but outer ring creeping exists under rotating load on the outer ring. AC bearing can also be installed as a floating side bearing to accommodate expansion of shaft by heat as it is more axial. Before installing the bearing into the housing, a high viscosity oil (base oil viscosity, 100 mm^2/s or more) or grease must be applied to the space between two O-rings. This lubricant forms a thin oil layer on the bearing outer ring which prevents contact between the outer ring and housing, lowers the friction, and can minimize the occurrence of creeping by utilizing the friction force of the O-rings.

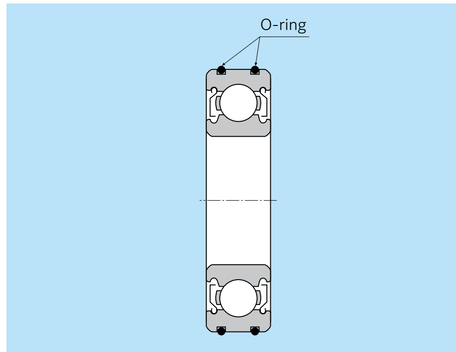

Fig. 3. AC bearing

(1) Allowable load

As is the case with the EC bearing, the load applied to an AC bearing shall be limited to C_p **(see dimension table) in order to ensure the strength limit of the modified outer ring is not exceeded**.

(2) Housing dimensions and shape

Fig. 4 shows the recommended shape of steel housings, and **Table 4** shows the dimensions.

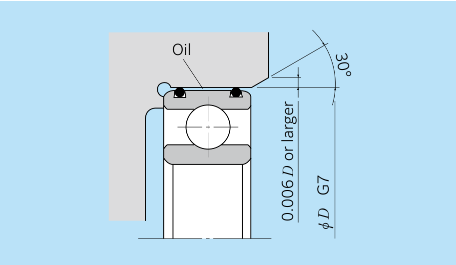

Fig. 4. Design of housing

Table 4 Dimensions and design

Housing bore tolerance	G7
Housing bore entrance chamfer	Max. 30°C
Housing bore chamfer undercut	0.006D or larger
Housing bore surface roughness *Ra*	2.5
Housing bore roundness	1/2 of bearing housing dimension tolerance

(3) Allowable temperature range

−25 to 120°C

1) Smallest allowable dimension for chamfer dimension r. 2) This bearing number is for double sealed and double shielded type bearings, but single sealed and single shielded type are also available.

3) This dimension applies to sealed and shielded bearings.

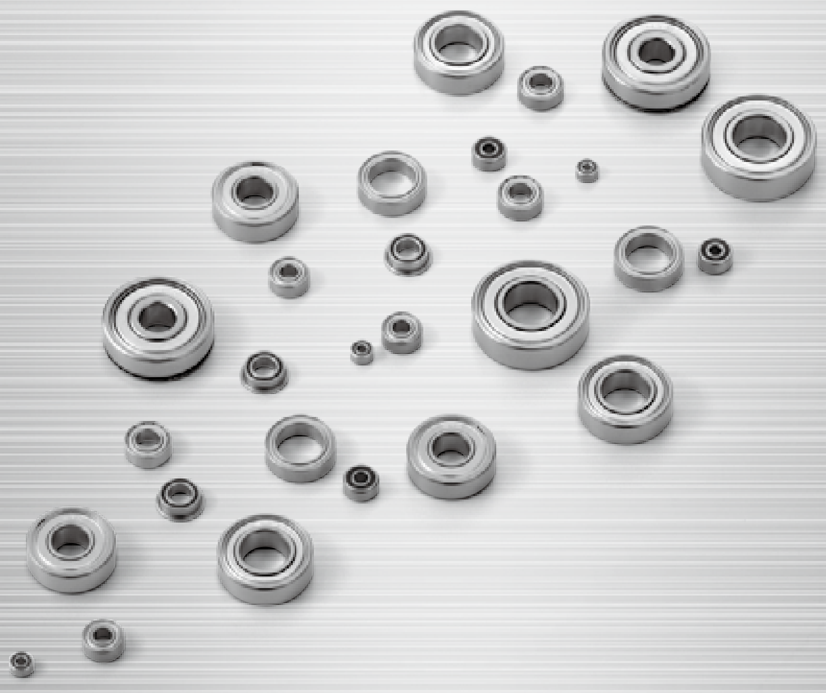
Miniature and Small Size Ball Bearings



Open type

Shielded type

Shielded type with snap ring

1. Design features and characteristics

The dimensional range of miniature and extra small bearings can be found in **Table 1**. Boundary dimensions for both metric and inch series are in accordance with the internationally specified ISO and ANSI/ABMA standards. The most widely used sealed and shielded type ball bearings generally have a 1 - 2 mm wider width dimension than open type bearings.

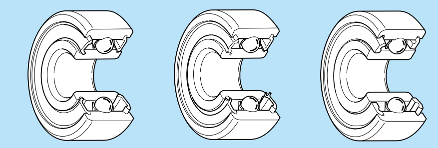
The main variations of these bearings are shown in **Table 2**. Miniature and extra small size ball bearings can also utilize snap rings, which simplify assembly within the housing. These bearings with snap rings can also be found in the dimensional tables in this catalog.

Among the most generally used sealed and shielded bearings are standard ZZ and ZZA type which incorporate non-contact steel shield plates. **Fig. 1** also shows non-contact type rubber sealed LLB and resin sealed SSA type bearings, as well as the contact-type rubber sealed LLU bearing.

Section "11. Lubrication" provides additional information on grease filled within the sealed and shielded bearings.

Table 1 Dimensional range

Bearing	Dimensional range
Miniature ball bearings	Nominal outer diameter $D <$ 9mm
Extra small ball bearings	Nominal bore diameter $d <$ 10mm Nominal outer diameter $D \geqq$ 9mm



Rubber sealed (non-contact type) LLB   Rubber sealed (contact type) LLU   Resin sealed (non-contact type) SSA

Fig. 1

Table 2 Main types and construction

Type	Standard type code			Flange-attached type code		
	Construction	Metric series	Inch series	Construction	Metric series	Inch series
Open type		6 BC	R		FL6 FLBC	FLR
Shielded type		6 X X ZZ W6 X X ZZ WBC X X X ZZ	RA X X ZZ		FL6 X X X ZZ FLW6 X X X ZZ FLWBC X X ZZ	FLRA X X ZZ

Note: 1. Representative codes are shown. For further details, please refer to dimension tables.
2. May change to ZA or SA for shielded type bearings, according to the bearing number.

2. Standard cage type

Pressed steel cages are standard for miniature and small size bearings.

3. Dimensional and rotational accuracy

The accuracy of miniature and extra small ball bearings complies with JIS standards. Accuracy of these bearings is defined by Table A-54 in section "6. Bearing Accuracy." Flange accuracies are listed in **Table 3**.

Table 3 Tolerance and tolerance values for outer ring flange

Unit: μm

Accuracy class		Outer diameter dimensional tolerance Δ_{D1s} or Δ_{D2s} Upper	Lower	Outer ring surface runout for rear surface S_{D1} Max.	Back face axial runout S_{ea1} Max.	Width deviation Δ_{C1s} or Δ_{C2s} Upper	Lower	Width unevenness V_{C1s} or V_{C2s} Max.
ISO standard	Class 0	* (see table below)		—	—	Identical to same bearing's inner ring Δ_{Bs}.		Identical to same bearing's inner ring V_{Bs}.
	Class 6			—	—

18	30	+330	−52
30	50	+390	−62

Miniature and Small Size Ball Bearings NTN

4. Radial internal clearance

Radial internal clearance is defined by Table A-88 in section "8. Internal Clearance and Preload."

The radial clearance values for high precision miniature and extra small bearings can be found in **Table 4**.

Table 4 Radial internal clearance for high precision bearings

Unit: μm

MIL Standard	Tight				Standard						Loose		Extra Loose	
Code	C2S		CNS		CNM		CNL		C3S		C3M		C3L	
Internal clearance	Min.	Max.	Min.	Max.	Min.	Max.	Min.	Max.	Min.	Max.	Min.	Max.	Min.	Max.
	0	5	3	8	5	10	8	13	10	15	13	20	20	28

Note: 1. These standards are specified in accordance with MIL B23063. However, **NTN** codes are shown.
2. Clearance values do not include compensation for measuring load.

Angular Contact Ball Bearings

Angular contact ball bearing

Four-point contact ball bearing

Double row angular contact ball bearing

1. Design features and characteristics

1.1 Angular contact ball bearing

Angular contact ball bearings are non-separable bearings with a defined contact angle in the radial direction relative to the straight line that runs through the point where each ball makes contact with the inner and outer rings (see **Fig. 1**). **Table 1** provides information on contact angles and their designated codes.

In addition to radial loads, angular contact ball bearings can accommodate single direction axial loads. Since an axial load is generated from a radial force, these bearings are generally used in pairs. **Table 2** shows general angular contact ball bearing characteristics, **Table 3** shows information on using duplex (side by side) angular contact ball bearings, and **Table 4** shows information on multiple-row angular contact ball bearings.

For bearings with a contact angle of 15° and bearing tolerance JIS Class 5 or higher, see special catalog "**Precision rolling bearings (CAT. No. 2260/E)**".

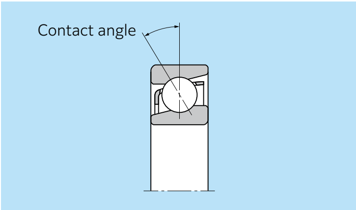

Fig. 1

Table 1 Contact angle and contact angle codes

Contact angle	15°	30°	40°
Contact angle code	C	A 1)	B

1) Contact angle symbol A is omitted from part number.

Table 2 Angular contact ball bearing types and characteristics

Type	Design	Characteristics
Standard type		● Available in bearing series 79, 70, 72, 72B, 73, and 73B. ● Contact angles: 30° and 40° (with B) available. ● Standard bearing cage type differs depending on bearing number. (see **Table 5**)

Table 3 Duplex angular contact ball bearings — types and characteristics

Duplex type		Characteristics
Back-to-back arrangement (DB)		● Can accommodate radial loads and axial loads in either direction. ● Has a large distance between the acting load centers of the bearings, and therefore a large momentary force load capacity. ● Allowable misalignment angle is small.
Face-to-face arrangement (DF)		● Can accommodate radial loads and axial loads in either direction. ● Has a smaller distance between the acting load centers of the bearings, and therefore a smaller momentary force load capacity. ● Has a larger allowable misalignment angle than back-to-back duplex type.
Tandem arrangement (DT)		● Can accommodate radial loads and single direction axial loads. ● Axial loads are received by both bearings as a set, and therefore heavy axial loads can be accommodated.

Note: 1. Duplex angular contact ball bearings are manufactured in a set to specified clearance and preload values; therefore, they must be assembled side by side with identically numbered bearings and not be mixed with other arrangements.
2. To satisfy specified clearance and preload values, tightening must be performed until the inner ring width surfaces or outer ring width surfaces come in contact with each other.

Table 4 Combination examples of multiple-row angular contact ball bearings

Duplex type	3-row arrangement	4-row arrangement
Back-to-back arrangement	 (DBT)	 (DTBT)
Face-to-face arrangement	 (DFT)	 (DTFT)
Tandem arrangement	 (DTT)	 (DTTT)

Note: Other combinations are also available. Consult **NTN** Engineering for details.

1.2 Four-point angular contact ball bearings

Four-point angular contact ball bearings have a contact angle of 30° and a split inner ring. As shown in **Fig. 2**, when the inner and outer rings receive a radial load, the ball contacts the inner and outer rings at four points. This construction enables a single bearing to accommodate axial loads from either direction, and when under a simple axial load or heavy axial load, the bearing relies on two contact points like ordinary bearings.

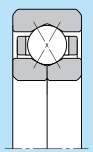

Fig. 2

■Flush ground

"Flush ground" is the name given to the finishing method shown in **Fig. 3** where the offset of the front and back faces of the bearing are ground to the same value. This allows a designated clearance or preload value to be achieved when using bearings with identical codes in DB or DF orientations. DT series bearings can also be used in various arrangements to achieve uniform load distribution.

General angular contact ball bearings are not flush ground. If it is necessary to flush grind any of these other bearings, please consult **NTN** Engineering.

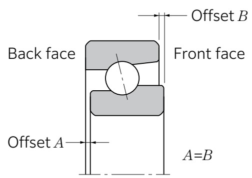

Fig. 3

1.3 Double row angular contact ball bearings

The structure of double row angular contact ball bearings is designed by arranging two single row angular contact bearings back-to-back in duplex (DB) to form a single bearing with a contact angle of 25°.

These bearings are capable of accommodating radial loads, axial loads in either direction, and have a high capacity for moment loads.

As shown in **Fig. 4**, sealed and shielded type double row angular contact ball bearings are also available. Standard loads vary from those of open type bearings.

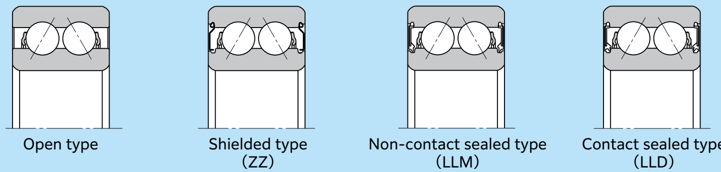

Fig. 4

2. Standard cage type

Table 5 lists the standard cage types for angular contact ball bearings.

Table 5 Standard cages for angular contact ball bearings

Type	Bearing series	Resin cage	Pressed steel cage	Machined cage
Standard type	79	7904~7913	—	7914~7960

Note: For bearing series 79 and 70, inner rings are constructed with groove abutments on both sides. Therefore, the inner ring chamfer dimension r_1 is identical to dimension *r*. Furthermore, the radius r_{1a} of the shaft corner roundness is likewise identical to r_a.

Note: For bearing series 79 and 70, inner rings are constructed with groove abutments on both sides. Therefore, the inner ring chamfer dimension r_1 is identical to dimension r. Furthermore, the radius r_{1a} of the shaft corner roundness is likewise identical to r_a.

Single row | Back-to-back arrangement (DB) | Face-to-face arrangement (DF) | Tandem arrangement (DT)
